The greatest threats facing herbal medicine availability today are sustainable harvesting and management of herb reservoir found around dwelling communities [111]. The extraction method of herbal medicines differs from one region to another and is exploitative in most cases. For instance, most herbs are extracted from stem bark and roots, hence exposing the plant to local extinction and in some instances death [111, 114]. In addition, overharvesting of herbal medicines has the potential to make endangered plant extinct in a short period of time [111, 114]. The uncontrolled utilization and harvesting of herbal medicines by community members to meet the constant health demand are responsible for the death of many plants with huge medicinal properties. Extraction methods like stem debarking, cutting, and uprooting affect the conservation and management of herbal products on a sustainable basis. Stem debarking, for instance, blocks the flow of plant material from the root to the leaves, thereby increasing insect attack and shortening the life of the plant [115].

Furthermore, the rapid exploitation of herbal products through global warming, urban sprawl, decline in natural ecosystem [106], and population growth posed a serious threat to the future sustainability of herbal medicines around the world [116]. In such, the overexploitation of herbal products across the world has resulted in the decline of herbal medicines and the emergence of gene pool and the loss of biodiversity for the current and future generation [116].

6.5 Lack of Value Addition Activity in Herbal Products

The high demand of herbal medicines motivates herbal practitioners to produce more, but the absence of value addition activity renders herbal products inferior to Western drugs [117]. Although herbal medicines are known to be a good source of biomolecules and other phytochemical derivatives, the presence of minimal value addition activities in the processing and preparation of the herbs prevents breakthrough in complex problems supposed to be cured by herbal products. The absence of value addition in herbal medicines discourages investment, reduces income generated through herbal product sale, and stalls local livelihood and economic activities [117]. Value can be added to the raw herbal products harvested from the wild through adequate packaging, branding, drying, milling, labeling, and mixing different products to form a remedy that can cure more sicknesses. In some parts of the world, the harvesting of herbal products is done haphazardly, and as such, drying, grading, storage, and improper processing influence the value of the final herbal products [118].

6.6 Poverty and Illiteracy of Herbal Medicine Users

Poverty is a big problem in most regions or countries where herbal medicine reliance is high. Recent literature suggests that high poverty and illiteracy rates are the major sources of unsustainable herbal medicine harvesting, prescription, and exploitation [119]. Studies have recently detected a relationship between poverty and mass exploitation of natural resources including herbal products. Furthermore, illiteracy and unemployment in herbal resource-rich communities pose a threat to the sustainability and conservation of resources due to massive overexploitation [118]. Poverty-stricken and deprived communities consider herbal medicine as the only alternative source of healthcare and income and as such exploit the resources to meet their increasing daily demands [118] unsustainably.

6.7 Impacts of Climate Change Uncertainties on Herbal Medicine

According to Applequist [120], climate change has proven to have adverse effects on both human and plant species. For centuries, herbal products from plants have benefited humanity in diverse ways especially in communities where western medicine are difficult to reach or purchased. Nonetheless, climate change uncertainties and vulnerabilities threaten the abundance and sustainability of these herbal therapies around the globe [120]. The evolving trend in climate change uncertainties in the form of drought, landslides, flooding, erratic rainfall pattern, and desertification poses a serious challenge against plant extinction [119]. In drier regions around the world, climate change uncertainties are leading to mass extinction of valuable plant resources and wild animals. In addition, climate change has had a detrimental effect on herbal plants through decline in herbal plants and to some extent extinction of some herbs. Moreover, climate change affects plant survival, phytochemical properties, and production ability of most plants. In some ecosystems, climate change has altered the environmental conditions and ecological setup [120–123].

6.8 Effects of Anthropogenic Activities on Herbal Medicine Sustainability

Time and again, traditional medicine has proven to be a reliable source of medicines capable of curing and preventing various diseases especially in developing countries where locals can't afford to buy expensive western drugs. However, anthropogenic activities continue to hinder the growth and survival of herbs with important medicinal properties [124]. In such, herbal medicine abundance and availability have been altered by anthropogenic activities [125]. In recent times, shifting cultivation, charcoal and firewood collection, land use change activities, and livestock grazing have resulted to the decline in traditional herbs used as medicine to cure ailments [124].

7 The Way Forward in Promoting Herbal Medicine Usage and Sustainability

For herbal medicine production to be sustainable, some measures and policies need to be put in place in order to tackle challenges affecting herbal product availability and conservation (Fig. 3). Furthermore, herbal medicine usage should be strengthened at both national and regional levels through the inclusion of herbal medicine in the healthcare system of countries [126]. Furthermore, more search should be conducted to identify the potential phytochemical properties of some unexplored herbal plants. Furthermore, research collaboration between herbal and modern medicine practitioners should be encouraged and promoted at national and regional levels (Fig. 3). In addition, more value addition activities should be undertaken to upgrade herbal product appearance and intake in order to compete with western drugs. Stakeholder engagement and awareness raising drive on the importance of herbal medicine management and conservation should be encouraged at both national and regional levels.

8 Conclusions

Herbal medicine contribution to the healthcare system of most countries especially developing ones has been immersed over the years. It is concluded that plants with medicinal properties are globally a valuable source of healthcare medication more so

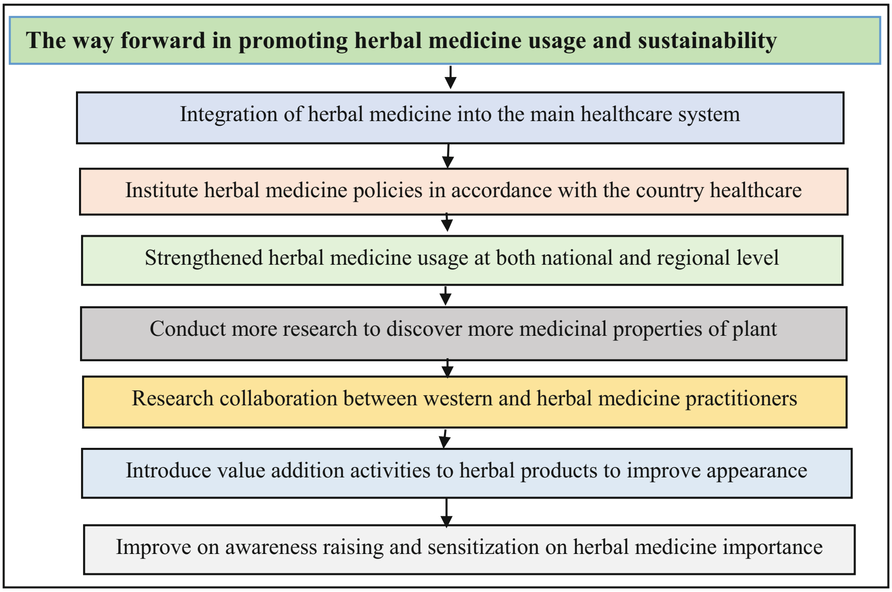

Fig. 3 Way forward in promoting the sustainable development of herbal medicine

for the less privileged in the society. The contribution of herbal medicines ensures the sustainable development of countries and their local economies. The upsurge in demand and value of herbal therapy today is closely linked with the rise in knowledge of the therapeutics, phytochemical properties, availability, and affordability of herbal medicine and the inexpensiveness of the herbal products as compared to modern drugs. The review accomplishes that herbal medicine sustainability is impeded by various factors ranging from policy absence, anthropogenic actions, uncontrolled deforestation, and limited collaboration between herbal and western healthcare practitioners. The review concludes that herbal drugs play a critical and central role in the sustainable development of local communities through the strengthening of healthcare system and the availability of drugs at any time among others. If adequate conservation and management measures are put in place, herbal products have the potential to trigger sustainable development revolution in the healthcare system of low-income countries. It is concluded that herbal medicine contribution to sustainable development is important in achieving the sustainable development goal 3 set for 2030. It is recommended that more research and collaboration be undertaken to integrate herbal medicine into the healthcare system of countries.

Abstract

Eco-friendly, bio-friendly, reasonably priced, and usually safe herbal medicines have moved from the margins to the center of medicine as a result of expanding research in the field of traditional medicine over the past few decades. A variety of herbal medicines have been created over the past few decades for both the prevention and treatment of diseases that are safe for the environment, organically produced, and affordable due to extensive study in the conventional system of medicine. Natural herbs have been used for a long time to treat and prevent many illnesses. However, the major obstacles to the growth of herbal medicine include regulation, industrialization, biopiracy, inadequate infrastructure, overuse and irrational use of medicinal herbs, and loss of biodiversity. Promoting and incorporating herbal medicines into basic healthcare develops sufficient capacity enhancement. This should be viewed as a sustainable route. It possesses the potential to support the Sustainable Development Goals (SDG) and the promotion of herbal medicines by the World Health Organization (WHO), as well as to facilitate the development of new drugs, improved access to healthcare, the preservation of forest resources, and assistance in bridging socioeconomic gaps.

1 Introduction

The utilization of plant species, particularly those having medicinal characteristics, has been essential for human survival throughout the evolution of human cultures [1]. Since their earliest beginnings, which date back to 8500 BC [1], medicinal plants have offered humankind curative therapies. Traditional Chinese medicine and Ayurveda are two notable cultures that have used and continue to use medicinal plants [2]. However, during the colonial era, these medical practices were disregarded and even made illegal by officials because they were thought to be primitive and unscientific. To use the potent medicinal substances found in plants as components in allopathic medicines, scientists began to extract and alter them when chemical analysis was accessible in the first decade of the nineteenth century [4]. At least one active component originating from plants is found in at least 25% of allopathic prescription drugs [88]. According to a recent study, herbal medications are incredibly safe and equally efficient as conventional ones. Figures show that only 15% of the 250–400 thousand plant species in the globe have undergone phytochemical investigation, and only 6% have undergone systematic biological activity screening [89]. As essential medications, more than 120 chemical compounds derived from plant sources are used, and over 60% of drugs used in therapeutic uses involve natural substances or their derivatives [90].

The word "herb" is used explicitly in botanical literature to describe nonwoody vascular plants without enduring wood stems, such as annual, biennial, and specific perennial crops (including the majority of the monocot species). The term is used more widely in the study of pharmacology, where it is used as a synonym for "plant" to refer to all trees, shrubs, and herbs. Herbal medicine is defined by the WHO (World Health Organization) as a practice that uses herbs, herbal supplies, herbal preparations, and final herbal products that include active substances extracted from plants, other plant materials, or combinations of these [3]. The stems, leaves, blossoms, roots, and seeds of plants are used to make these herbs [4].

Additives like dilute solutions, solvents, or preservatives are frequently added to plant-based medications in addition to plant components, either in their raw or processed forms or active substances [4, 5]. These active substances protect the plant from harm and illness and improve its scent, flavor, and color. They are categorized by scientists as phytochemicals and fall under a variety of categories, such as tannins, alkaloids, flavonoids, glycosides, saponins, and terpenoids [6]. The potential for phytonutrients to improve the well-being of people has been established over time by science [7]. Herbal sedatives and stomachic combinations, for example, contain aromatic plant species with medicinal essential oils with antibacterial, stomach-soothing, and antispasmodic properties. Species of plants that have a significant tannin content are used in mixes for the treatment of stomach ulcers and diarrhea because they typically have antibacterial, astringent, and anti-inflammatory qualities [8, 9]. Herbal remedies can potentially improve access to healthcare and help realize Sustainable Development Goal (SDG) number 3 – wellness and excellent health – in addition to playing a part in the economic, social, and environmental sustainability spheres. The production of medicinal plants can be used to improve income generation or as a source of alternate income, safeguard biodiversity, and foster regional economic development while preserving forests [10]. By keeping forests healthy, we may avoid irrevocable climate change. For instance, the Amazon is a significant carbon sink and contributes significantly to the global and regional water cycle [11, 12]. Severe changes in land use, particularly those connected to extensive deforestation and forest degradation, have been indicated to significantly influence regional and worldwide precipitation patterns [13]. Recognizing herbal medicines and their ability to stop forest destruction is now more crucial than ever before. Additionally, it might cause people to quit their present, less sustainable jobs in the forestry and mining industries. As a result, a bioeconomy may result in an expanded enterprise that, in spite of generating income, has the power to support and protect natural environments from harmful land use practices. The value chain must be analyzed to ensure all activities are sustainable, as development carries the danger of increased strain on natural ecosystems [13]. Additional study on the subject is necessary to improve awareness of how herbal medicine development may help ensure healthcare access, biodiversity preservation, and socioeconomic growth in this environment.

2 The Historical Significance of Herbal Therapy

According to historical Babylonian reports, people first used plants as medicines 60,000 years ago. At least 5000 years have passed since the writing of herbal therapy in Egypt and China, and 2500 years have passed since Asia Minor and Greece [14]. Multiple herbal medical systems exist, and the foundations and procedures in each are affected by the part of the world in which it was developed [15]. China has utilized traditional Chinese medicine (TCM) for quite a while [16]. The Celestial Farmer's Classic of Herbalism, the world's earliest herbal text, was written in China approximately 2000 years ago. Herbal written material provides access to multiple herbal pharmacopoeias and numerous monographs on specific botanicals [17]. Ayurveda is a historical Hindu medical discipline practiced for more than five thousand years in India and was created by ancient Hindu practitioners and philosophers. More than 1500 floral species and around 10,000 mixtures are exhaustively described in its Materia Medica. Unlike traditional Western medicine, the Indian government recognizes Ayurveda as an extensive healthcare system [18]. Kampo medicine, a category of Japanese herbal medicine with a history extending back over 1500 years, consists of 148 unique formulations [19].

2.1 Sustainable Development and Global Commitments

The intrinsic worth of natural assets and their social advantages must be comprehended, particularly in light of the global prevalence of medicinal plant use. But when seen from the viewpoint of environmental history, it stands out for the ways that people have used nature to further their ends. Inequality results from industrialized countries' increased consumption levels without considering the requirements of developing countries [20]. A human-centered viewpoint has made many environmental problems worse and contributed to the present endangerment of natural resources and medicinal plants. Since the 1987 release of the Brundtland Report, in which sustainability is defined as "addressing the demands of the present without jeopardizing the capacity of future generations of people to meet their own needs," sustainable growth has been an essential strategy for development [21]. In addition, it ensures continual access to the resources necessary to establish a less disruptive and highly resource-intensive economy [22]. It is an approach designed on the idea that economic, ecological, and social factors must work together to assure economic growth while fulfilling community and ecological necessities [20]. Rio de Janeiro, Brazil, hosted the United Nations Conference in 1992 on the Environment and Development, resulting from a growing global environmental movement. Agenda 21 results from the Earth Summit, which focused on the emergent need for a worldwide sustainable strategy that requires national, regional, and municipal effort [20, 22]. Agenda 21 included 120 recommendations for action. Over time, Agenda 21 was incorporated into the United Nations Sustainability Goals and Millennium Development Goals (SDGs and MDGs). To ensure that the needs of people are catered to both now and in the future, they were established in 2015 and include 17 goals and 169 targets that cover a broad range of topics. Regarding the requirement to appreciate medicinal plants as an element of primary healthcare, successful promotion and integration of herbal medicines could lead to a surge in the use of therapeutic plants and the development of the herbal medicines supply chain. A story that directly seeks to attain SDG 1 (No poverty), SDG 2 (Good health and well-being), and SDG 15 (Life on land) can be considered a means of achieving sustainable development (United Nations 2021).

2.1.1 SDG 1: No Poverty

Poverty affects freedom, health, and education and adversely affects the economy. This is particularly evident in emerging nations where poor infrastructure and service delivery, rural inequality, and environmental degradation are the leading causes of rural poverty [23]. Agroforestry and the incorporation of medicinal plants can help enhance livelihoods and contribute to the eradication of poverty in all its forms. SDG 15 (Life on land) has two goals that must be achieved to address the world's severe environmental concerns (United Nations, 2021).

2.1.2 SDG 3: Good Health and Well-Being

Incorporating plants for medicine into healthcare facilities can boost the availability of healthcare in both urban and rural areas, which is crucial for sustainable development. This is especially crucial in light of the effects of the COVID-19 pandemic and its spread of diseases such as AIDS, malaria, and neglected tropical diseases [24]. Plants with medicinal properties must develop new medications to improve healthcare.

2.1.3 SDG 15: Life on Earth

Earthly existence of protection, restoration, and development of ecosystem services and biodiversity require sustainable land use. The human population of tropical regions, which relies on natural resources for survival, must possess two characteristics to preserve its means of subsistence and confront the forthcoming difficulties of climate change [25]. Growing utilization and demand for medicinal plants may lead to an appreciation of the extant forest and its biodiversity in this context. Promoting the preservation of ecosystems and species in addition require equitable allocation of genetic resources by establishing a direct connection between medicinal plants and biodiversity.

The World Health Organization emphasizes the use and importance of safeguarding plants for medicinal purposes as one of the main actors in attaining the Sustainable Development Goals, which call for universal availability of healthcare [26, 27]. At the 1978 International Conference on Primary Healthcare held at Alma Ata, Kazakhstan, the World Health Organization (WHO) and the United Nations International Children's Emergency Fund (UNICEF) emphasized the need for immediate global action [28]. Since then, the WHO has remained dedicated to recognizing and encouraging the application of medicinal plants, which led to the development of a program for conventional medicine whose current version encompasses the years 2014–2023 [29]. The program's objective is to assist participating nations in developing and implementing a strategic plan that considers their unique capacities, goals, and regulatory and legal frameworks. Promoting herbal remedies is crucial for developing an alternative to traditional practices [30].

2.2 Health, Poverty, and Livelihoods

High levels of cultural diversity affect people's health in developing countries, particularly in tropical regions which are additionally affected by scarcity and infectious diseases [31, 32]. Since 1940, more than 300 contagious illnesses have emerged, impacting approximately 15 million individuals every year in the globe. In addition, one billion people worldwide are afflicted by neglected tropical diseases that have become endemic to rural areas with scarce resources and threaten the livelihoods of the people affected [32]. In the same regions, chronic diseases are also on the rise. Mexico will be used as an example because it is one of the biggest economies in Latin America and is still grappling with poverty and rural population inclusion [33]. Three thousand healthcare posts and 71 rural hospitals were established despite their attempts and accelerated expansion of their healthcare systems. As a result of the change, their healthcare system must now treat diseases connected to poverty and contemporary lifestyle disorders [31].

In the words of **Mphande** [32] who explains the association between health, poverty, and means of survival, the economic and health conditions of the population in developing nations influence their livelihood choices (Fig. 1). People are becoming increasingly aware that poverty can rapidly develop when a family's earnings are

Fig. 1 The relationship between poverty, health, and way of life with markers for each

restricted. However, declining health can also indirectly contribute to poverty by reducing the ability to support a family. This condition generates an endless cycle that jeopardizes all three pillars necessary for a prosperous existence. Figure 1 depicts the association between health, poverty, and means of subsistence, as well as the corresponding metrics for each factor.

3 Present State of Herbal Medicine: Higher Plants Are the Source of Modern Medicine

Due in significant part to medicinal plants, new medications are developed. According to the WHO, approximately 25% of current pharmaceuticals are derived from botanicals utilized in traditional medicine. Plenty more are synthetic analogues created using plant-derived model substances as a starting point. In addition, the WHO now recognizes medicinal plants as an integral component of primary healthcare [33]. Medications derived from plants have fundamentally transformed contemporary treatments. Vinblastine, extracted from the *Catharanthus rosesus* plant, is effective against malignancies of the testis, pharynx, Hodgkin's lymphomas, choriocarcinoma, and non-Hodgkin's lymphomas, among others [34]. The phophyllotoxin extracted from *Phodophyllum emodi* possesses anti-lymphoma, anti-lung, and anti-testicular characteristics. Taxol, which originates from *Taxus brevifolius*, is used to treat lung and ovarian tumors that have spread to these tissues. In 1953, serpentine was identified in the root of *Rauwolfia serpentina*, and it has been utilized successfully to treat hypertension and lower blood pressure [35]. Between 1950 and 1970, the US pharmaceutical industry reportedly introduced approximately 100 novel plant-based medications, which include deserpidine, reseinnamine, reserpine, vinblastine, and vincristine. Ectoposide, guggulsterone, teniposide, nabilone, plaunotol, Z-guggulsterone, llentinan artemisinin, and ginkgolides comprised among the novel plant-derived medications isolated between 1971 and 1990. More plant-based medications, such as Paclitaxel, Toptecan, Gomishin, and Irinotecan, are released to the pharmaceutical market between 1991 and 1995 [36]. Several researchers have recently discovered the chemical substances like quinine, digoxin, aspirin, ephedrine, atropine, and colchicine extracted from plants [37, 38].

3.1 Trends in Herbal Medicine Use

Herbal medicine continues to be extensively utilized in developing nations, and in the industrialized world, utterly 70% of physicians in France and Germany routinely prescribe herbal medications, based on estimates. Additionally, an increasing number of individuals are using herbal remedies [39]. Predictions indicate that 80% of the global population will use botanicals; this number could reach 95% in developing nations [40]. Traditional herbal remedies account for 30–50% of all pharmaceuticals used in China. In Ghana, Mali, Nigeria, and Zambia, herbal remedies constitute 60% of the first-line treatment. It is estimated that more than 50% of individuals in industrialized nations such as Europe, North America, and others have tried herbal remedies at least once [41]. In San Francisco, London, and South Africa, 75% of HIV/AIDS patients utilize natural treatments. Seventy to ninety percent of Canadians and Germans have used herbal remedies at least once. It is estimated that 158 million individuals in the USA use natural remedies, which continues to rise. The market for herbal remedies is presently worth over $60 billion annually and continues to expand [41, 42]. It is also important to remember that adult populations are more likely to use traditional and herbal medications. Since chronic diseases are increasingly common in this population, the long-lasting adverse effects of conventional medication therapies frequently discourage patients from using them for an extended period. Nevertheless, consistent application of herbal remedies offers a treatment without adverse effects. Due to these needs, herbal medicine has attracted interest and is rapidly gaining global recognition.

4 Challenges in the Medicinal Plants Sector

Human cultures in developing nations rely heavily on forest goods for their economic systems and way of life, so the continued growth of humanity is one of the factors causing concern regarding our capacity to meet our everyday needs for food and medicine. Due to this inclination, causing the forest and the goods it produces to continue to erode, it is difficult to satiate demand and safeguard irreplaceable bioresources [43]. The number of species in the Materia Medica is rising, but their purity and precise identification requirements have not kept pace. In addition, it is crucial to protect endangered medicinal plants due to the global deforestation crisis and the rise in herbal and ethnomedical practices. An enormous amount of plant materials and extracts are needed for the manufacturing of herbal formulations as well as for related industries, including food, nutraceuticals, cosmetics, perfumes, and toiletries, and because India, Tibet, China, and many African and Latin American countries are renowned for their traditional medicine, the majority of which, including Chinese medicine and Ayurveda and Unani in India, is primarily based on herbs [44]. Since market prices for medicinal plants and their by-products do not accurately reflect profits, supply, or demand, they only provide a nebulous understanding of how the market functions. After thoroughly examining the available information regarding the medicinal plant industry, we have identified the following essential characteristics and challenges.

4.1 Rising Demand

The World Health Organization (WHO) estimates that the annual market for medicinal plants is presently worth \$14 billion [45]. According to a WHO forecast, by 2050, the global market for restorative plant-derived raw materials will have grown between 15 and 25% yearly and be worth \$5 trillion. The annual value of medicinal plant trade in India is estimated at USD 1 billion [46]. India exported nearly three times as many Ayurvedic products during the previous two fiscal years (2001–2002 and 2002–2003). Due to the expected rise in demand for medicinal plants, numerous species were overharvested from the wild, causing their populations to decline. For instance, substantial quantities of Himalayan yew (*Taxus baccata*) have been harvested from the wild since its extract or parts, Taxol, have been approved for treating ovarian cancer. *Aconitum heterophyllum*, *Nardostachys grandiflora*, *Dactylorhiza hatagirea*, *Polygonatum verticillatum*, *Gloriosa superba*, *Arnebia benthamii*, and *Megacarpoea polyandra* are varieties of North Indian medicinal plants that have been overused for medicinal purposes and are now rare or endangered. Multiple species of medicinal plants are imperilled by excessive harvesting in the wild as they are used to treat a wide range of diseases [47, 48]. For instance, the *Hemidesmus indicus, Gloriosa superba, Aegle marmelos*, and *Phyllanthus emblica* are used to treat 34 diseases. The excessive use and ongoing devastation of medicinal plants [49] have hurt on the genetic diversity, supply of food, and manner of life of indigenous people who reside on the forest's periphery.

4.2 A Rise in Rarity

Due to the ongoing exploitation of several native medicinal plant species [50] and significant habitat destruction over the past 15 years [51], the overall population of high-value medicinal plant species has diminished over time. Biodiversity that is utilized by humans poses the biggest threat to medicinal plants [52]. Among the factors contributing to the disappearance of medicinal plant varieties is the decline of traditions that have governed the use of natural resources [53, 54]. Contemporary socioeconomic factors have repeatedly weakened these established regulations [55]. Numerous additional variables, such as habitat particularity, a restricted distributional scope, land use changes, the introduction of non-native species, habitat modification, alterations in the climate, significant grazing by livestock, the explosive growth of populace, population dispersion and deterioration, and genetic drift are responsible for the rarity of medicinal plant species [56–59]. Viruses, herbivores, and seed predators are natural adversaries that can significantly reduce the presence of rare species of medicinal plants in a given area [60, 61]. Even though humans and other animals consume medicinal plants, humans also experience physical disorders that can be treated by various species within the same genus. Several species of *Swertia*, for example, are used to treat malarial fever. Similar to how various *Berberis* species are used as a source of berberine to treat specific eye conditions, *Berberis* species appear in a diversity of forms. Moreover, even though they are less threatened by extraction than varieties with no alternatives, various species within the same genus have varying chemical concentrations, so there is a demand for them. Due to the absence of data/information on the population size and prevalence of rare plant species in the field, the classification has been limited to a handful of species based on herbarium specimens and expert opinion. Current assessments call into doubt the precision with which threat groups are assigned to species, particularly the number of endangered taxa in a given region. The problematic topography, hostile climate, and short plant life cycles exacerbate the difficulties associated with species assessment in the mountainous regions regularly at high altitudes. The majority of the material that is currently accessible was obtained from the more accessible regions of these mountains. Indigenous groups and commercial herb hunters also explore the same regions for medicinal plants. Because it varies in areas in which these rare medicinal plant species have been collected infrequently or never, the predicted density of classified rare medicinal plants is inaccurate [62].

4.3 Medicinal Plants Cultivation

Only 1% of the world's known plant species had access to agrotechnology, and less than 10% of those do not know how to reproduce [63, 64]. This pattern suggests that the development of agrotechnology ought to be one of the main study areas. To satisfy the growing demand for medicinal herbs, these plant types need to be cultivated. In addition to meeting the present need, agriculture may help preserve the genetic variety of medicinal plants in the wild. Agriculture enables the production of identical elements from which reliable standardization of products can occur. In addition, cultivation increases the likelihood of genetic advancements, improved quality control, and enhanced species identification. In large-scale cultivation, selecting the planting medium is another important consideration. Therefore, the plant material must be high quality, packed with active components, resistant to diseases and pests, and tolerant of its environment. To successfully cultivate all medicinal plants extensively, one must determine whether monoculture or polyculture is preferable.

Because many species of medicinal plants are mainly found in forest cover, agroforestry provides a valuable method for their farming and sustenance by:

1. Using medicinal plants that can survive in the shade as understory plants in multilevel ecosystems
2. Integrating fast-growing medicinal plants into established tree plantations
3. Planting plants with therapeutic properties for shade purposes

Regardless, it is recognized that cultivating medicinal plants is a complex undertaking, as demonstrated by the history of therapeutic plant cultivation. Medicinal plants like *Saussurea costus* have a lengthy cultivation cycle. Therefore, many farmers in the trans-Himalayan region of Northern India have shifted to cultivating common commodities such as peas, potatoes, and hops (*Humulus lupulus* [65]). It isn't easy to grow herbs for medicinal purposes in India since they are present in large amounts and are less expensive than many seasonal crops [66].

4.4 Bioprospecting and Biopiracy: An Emerging Problem

The once-remote verdant forests are now integral to the demanding multicultural politics and fast-paced, profit-driven global economy. For policymakers and economists, the declining demand for forest products, particularly medicinal plants, poses a challenge. Local medicinal plant traditions are significant on a global scale. The Rio Convention on Biological Diversity established a framework for the responsible and regulated utilization of biological diversity. The current climate for bioprospecting is marked by increasing suspicion and animosity regarding biopiracy and the rights of developing and developed countries to reap the benefits sharing [67]. The vast majority of obstacles associated with the legal protection of indigenous wisdom and the payment of remuneration to indigenous herbal practitioners for their expertise are extraordinarily complex. One group identifies the present system of payment or sharing of advantages under intellectual property rights as a new legal form of biopiracy. In contrast, another identifies it as a means of protecting the rights of knowledge proprietors. The diverse methods and procedures used in India, the USA, Europe, Canada, and other nations to grant patents on medicinal plants have created confusion [68]. Typically, patent protection is unavailable for plants, plant-related developments, and plant products such as seeds, flowers, fibers, and resins. However, any living object created by humans in the USA, whether through reproduction or laboratory research, is patentable. The Indian Preservation of Plant Varieties and Farmer's Rights Act of 2001 rewards farmers who engage in breeding initiatives. This legislation also includes arrangements for distributing benefits that recognize local populations as contributors of plant material [69].

The patentability of products varies greatly across developed and developing countries, including India. There were 31,25,603 patent applications from 91 countries, but only 301,177 (9.6%) were registered in developing countries, which is very unfortunate as they are the habitat of numerous plants having medicinal properties. The rest were filed in developed countries; 2.3% of those enrolled are from developing nations and 0.2% are residents. In addition, 97.7% of all applications for patents filed to date have been submitted by nonresidents for the primary purpose of monopolizing markets for export in developing nations [70]. Developing countries and numerous scientists interested in using medicinal plants require specific laws regarding the recording of the nationalities of samples and the equitable distribution of the benefits within the countries of origin, the inventor, and business benefactors. Several developed nations are hesitant to embrace these clauses. These disagreements have irritated numerous scientists who argue that organic products will always be the finest resource for developing novel medications. In 2004, at the Kuala Lumpur Conference, the delegates of 188 nations decided to develop a structure acceptable to all signatories to reduce such disputes and prepare for the discovery of new drug sources. The proposed framework will thus be presented for discussion at the forthcoming meeting in 2006, which Brazil will host.

4.5 Enhancing the Market System Medicinal Plants

Herb gatherers, local middlemen, urban merchants, wholesale suppliers, producers, exporters, and herbal therapists are a few of the many involved players in the medicinal plant trade. The marketing structure for medicinal herbs is largely unregulated and unjust [55]. Typically, marginal cultivators and laborers are responsible for the harvest of medicinal plants. They earn money by selling therapeutic botanicals to cover everyday costs such as food, healthcare, and their children's education. They frequently ignore the genuine market prices for a vast array of medicinal plants. Even the vast majority of bottom-up stakeholders in the medicinal plant industry, which typically employs a top-down approach, don't realize there's a growing market for what they're selling. Farmers in the Chamoli district of Uttarakhand grew Kut (*Saussurea costus*) and Dolu (*Rheum emodi*). Yet they faced problems selling them because they were unfamiliar with the local distribution network. On the other hand, illegal trafficking of medicinal plants is widespread.

The following factors also pose challenges for the medicinal plant industry:

1. Many useful plants grow at an extremely slow rate.
2. Many medicinal plant species have a lengthy gestation time.
3. Inadequate methods of plant growth technologies for medicinal plant species.
4. Less production.

5. Unsuitable harvesting techniques.
6. Insufficient study on high-yield varieties.
7. Fluctuating demand and supply.
8. Poor manufacturers.
9. Insufficient marketing infrastructure – this term basically indicates that there aren't enough marketplaces selling these medicinal herbs. When we examine the market for accessing, storing, distributing, and adding value for different commodities (such as allopathy drugs), we can observe the significant difference.

Manufacturers frequently choose untamed plant species over cultivated medicinal herbs because wild plant species contain more chemicals. The harvesting seasons and various growth stages of a species also influence variations in chemical composition. The market for medicinal plants is largely underreported and inadequately regulated. Due to the extensive illicit commerce, the revenue generated by this industry is therefore inaccurate. The economic benefits and management costs of natural populations are frequently miscalculated [71].

4.6 Problems with Herbal Medications' Quality Control

Both intrinsic (genetic) and extrinsic factors, including the environment and good agricultural and collection practices (GACP), which include crop selection, cultivation, and harvest techniques, influence the overall quality of the basic materials used to produce botanical products. Combining these factors makes it difficult to conduct surveillance on basic ingredients. Implementing standard operating procedures (SOP) for authentication, quality, storage spaces, sanitation, and cleaning of raw materials is essential for achieving excellent laboratory and valuable manufacturing practices [72]. Concerns about the quality of the finished herbal product, especially mixed herbal goods, are common because of the many ways in which it is impossible to verify the presence of every single herbs or raw materials. Consequently, finished goods tend to be subject to stricter requirements and quality control procedures than other medications. By WHO recommendations, organizations for quality assurance and control measures have been established to oversee good manufacturing practices (GMP) for botanical products, licensing and labeling methods for their manufacture, commerce, and national marketing initiatives [73].

4.7 Harvesting and Processing Issues

The bad quality of herbal medicines results from various factors, including lack of processing technology, efficient farming practices, propagation methods, and a sloppy harvest, all contribute to poor quality produce [74].

Adulteration is the practice of using subpar replacements for the original drug substance. The replacement parts might come from the same or a different factory and be counterfeit, subpar, flawed, broken, or useless [75]. Adulteration can take place in two approaches:

- Intentional or direct adulteration
- Unintentional or indirect adulteration; for instance:
  1. Using artificially made ingredients, such as when nutmeg is combined with basswood or beeswax is tinted paraffin.
  2. Using subpar substances, such as *Ailanthus* as a belladonna adulterant or *Piper nigrum* as a papaya adulterant.
  3. With pharmaceuticals or poisonous substances, such as lead shot in morphine, limestone in asafetida, white oil presence in coconut oil, or cocoa butter combined with stearin or paraffin.
  4. Powdered substance adulteration, such as selling powdered liquor ice as cinchona or gentian combined with powdered olive stones [76].
  5. Dangerous levels of heavy metals have been found in many herbal formulations, including lead, arsenic, mercury, and others, according to research from several colleges [77].
  6. Adulteration of herbal formulas with readily available synthetic drugs: The US FDA found that some herbal supplements had sildenafil, warfarin, indomethacin, alprazolam, estrogen, etc. added to them.

4.8 Challenges Associated with Medicinal Plants' Clinical Research

Before describing a novel drug for conducting significant phase III trials, studying herbal drugs presents several problems that must be resolved. These challenges include ones connected to the study's plan, quality control, study budget, and regulatory requirements. The WHO released an operational strategy in 2005 covering the regulatory requirements that enable herbal product scientific trials [73].

Blinding is the most effective method for reducing bias and eradicating placebo effects in randomized clinical trials (RCT). Neither the two investigators nor the patient knows which therapy is being allocated, thus the name "double-blind." Maintaining double-blindness in herbal preparations can be challenging due to the multifaceted therapeutic approach employed in this healing process, which includes lifestyle, listening, counseling, explaining, and nutritional recommendations [78]. Other factors that must be taken into account and which may influence the results of clinical research include:

- The selection of controls: If the purpose of the investigation is to present evidence of a particular effect of the herbal medication, comparison comparability is required, therefore the rules are selected to be as similar to the group that will be receiving the therapeutic intervention as is practically possible. Finding a suitable power may be challenging for some odorous natural substances, such as ginger.

- Sample size calculations are necessary to carry out clinical studies.
- It has been recognized that there needs to be occupational harmonization, particularly in herbal product trials where the therapist is key [79].

4.9 Challenges Related to Pharmacovigilance of Herbal Medicines

Due to the growing use of herbal products including treatments worldwide, it is becoming increasingly essential to include herbal products and therapies in pharmacovigilance procedures. The major problem with implementation of pharmacovigilance in herbal medicines involves the following reasons [80] (Fig. 2).

Due to their extensive use worldwide, herbal medicines and products have been integrated into pharmacovigilance systems for quite some time. In this context, these goods' security has become a significant societal concern due to the necessity of basing risk assessments of herbal medications entirely on human interaction.

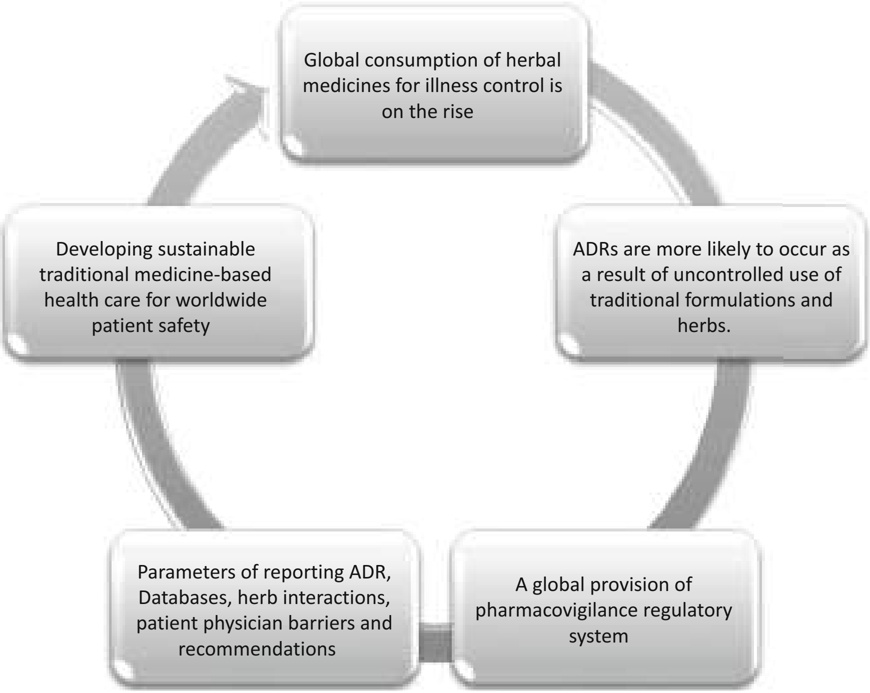

Fig. 2 Problem with implementation of pharmacovigilance

4.10 Problems with the Way Herbal and Conventional Drugs Interact

Many active phytoconstituents exist in different flora, each with a unique pharmacology, metabolism, and binding characteristic. These medications may also have pharmacokinetic or pharmacodynamic reactions with allopathic medicines. Garlic and ginger, which inhibit platelets and increase the risk of bleeding in warfarin-treated patients, increase bleeding in patients taking herbal drugs with a limited therapeutic window [81]. Other instances of how herbal medicines can combine

1. Ephedrine increases and prolongs the sympathomimetic impact by interacting with beta-blockers and MAO inhibitors (hypertensive crisis) [82]
2. Valerian and sedatives combination, causing more CNS depression [83]
3. Ginseng increases GABA metabolism and dopamine levels and reacts with MAO inhibitors [84]
4. Because of how KAVA (drug) and paracetamol combine, azole antifungals are more toxic to the liver [85]

5 Future Prospects of Herbal Medicine

Based on our understandings on herbal medicine, approximately 121 pharmaceutical drugs have been created in the last ten years [86]. At least 25% of currently available medications, including aspirin, picrotoxin, and many other substances with synthetic equivalents made from molecules extracted from plants, are thought to have their origins in plants [87]. Future expansion of the utilization of plants as sources of therapeutic agents will be accelerated by the increasing adoption of plant-based medications [86]. This has substantially increased the export of herbal remedies and attracted several pharmaceutical companies, which include multinationals [5]. The WHO's interest in chronicling ethnic communities' use of medicinal botanicals has resulted in increased scientific support for their application. Consequently, individuals will be better informed about the treatment's safety and effectiveness [14]. The oversight of herbs has contributed to the improvement of herbal goods, but additional adjustments are required to promote and advance high-quality research [4].

Conventional medical systems have gained popularity globally due to the public's fascination with herbal remedies and their astounding approval for their beneficial qualities with few to no adverse effects against various challenging health-related conditions. Sixty percent of the world's population currently relies on herbal or conventional treatments to treat malaria-related fever. Eighty percent of Africans, thirty to fifty percent of Chinese, forty-eight percent of Australians, seventy percent of Canadians, eighty percent of Germans, forty-two percent of Americans, thirty-nine percent of Belgians, and seventy-six percent of French individuals chose herbal or alternative treatments as their first line of defense against various diseases [88]. Seventy-five percent of people with HIV/AIDS in cities such as San Francisco, London, and the Republic of Africa use herbal medicines. Due to the availability of healthcare providers and affordability, countries such as Malaysia are spending more on costly prescription medications than on allopathic ones. Herbal medicines are gaining in popularity [89]. Projections show that many people in poor and developing countries get most of their healthcare from traditional drugs, and goods and remedies made from herbs are highly valued as essential parts of their cultures [90]. Herbal remedies are also widely used in many developed nations, while they are gaining increasing importance in the European Union, North America, Australia, and the UK [91].

5.1 Policies Proposed by AYUSH for the Healthcare Sector

- Ayush Ghutti, Bal Rasayana, Soubhagya Shunthi, Ajwain Ark, Pudina Ark, Punarnavadi Mandoor, and Tel Ksheerbala are some of the conventional medicines that will be added to the National Reproductive and Child Health (NRCH) Program.
- To come up with different ways for AYUSH remedies to work together with schemes like JSY-AYUSH, ICDS-AYUSH, breastfeeding early on, child development tracking, antenatal and postnatal care, etc.
- When used with the AYUSH medication Punarnavadi Mandoor to cure anemia during pregnancy.
- Verify if AYUSH treatments are accessible to major medical facilities.
- The use of AYUSH doctors in national programs for population stabilization and reproductive and child health.
- Utilizing the Indian methodology of traditional medicine to use in public health programs (NRHM), such as bringing in Ayurvedic medical professionals and paramedics.
- Spreading awareness of the Indian Traditional Medical System worldwide by giving seminars and conferences, working with foreign institutions, and initiating research there.
- The Institute for Research on Indian Systems of Medicine (CRISM) at the University of Mississippi in the USA was established by AYUSH as a joint Indo-American research facility.
- There are various universities in India teaching Ayurveda to international students from places like Japan, Italy, Russia, the USA, Australia, Holland, South Africa, Brazil, Canada, Hungary, Germany, France, Sri Lanka, Ukraine, and many more.
- Russia and India have entered an MoU that seeks collaboration in Ayurveda education, treatment, and study [92].

5.2 Industry

Over 10,000 industrialized traditional medicine facilities in India generate about $1 billion USD in net earnings from ISM and herbal systems. Over the past two decades, medications manufactured at AYUSH facilities have increased annually. Both ancient (such as pills, powdered form, medicinal oil, foods that have undergone fermentation, etc.) and modern-day medication forms can be used in the creation of Ayurvedic medicines (such as lotions, capsules, syrups, liniments, ointments, granules, and creams, among others). The Drugs and Cosmetics Act of 1940 governs this industry's production process and related regulations (1945). Entities involved with the production of both traditional and herbal medications must strictly adhere to GMP and GLP, which were developed by the Indian medical system's governing authorities [93].

5.3 India's Role and Future Perspectives

It is anticipated that herbal medicine will continue to be in high demand, and the prospects are optimistic. As a consequence of current ethnobotanical studies and the prolonged globalization of the trade markets for herbal remedies and medicinal plants [94, 95], the knowledge and use of innovative plant materials for domestic, medical, and industrial purposes are anticipated to increase. Moreover, India's economic growth depends on the prospective growth of botanical medicine. Priority should be given to ensuring sufficient quality assurance for herbal medication in order for consumers to purchase pure products. Herbal medicine's acceptance appeal is a significant advancement toward accomplishing the goal of delivering high-quality and affordable healthcare to people all around the world.

Demand for herbal medicines and supplements has skyrocketed with growing concern over the world's dwindling medical plant resources. India is in a privileged position regarding the variety of its climatic conditions and the profusion of its medicinal plant diversity. There is an extensive background to the Indian perspective on herbal medicines, which might be a source for future pharmaceutical innovations. According to reports, the Western Himalayan region is home to the medicinal plants that created 50% of British Pharmacopoeia's listed medications. The genetic variety of plants with therapeutic characteristics is just one example of the 8% percent of the entire world's biodiversity that may be found in India [96]. These facts demonstrate India's immense herbal medicine market potential. It is now critically important to combine modern and traditional knowledge. Following their discovery in plants, the pharmaceutical industry chemically synthesized several modern pharmaceuticals. Rare plants on the Indian peninsula are in danger of extinction due to excessive harvesting; saving them would benefit from the isolation, identification, and concomitant chemical response of therapeutically effective compounds derived from plant components. Growing economically valuable medicinal plants on wastelands can be an essential alternate income generator in rural areas. In Northeastern India, where numerous medicinal plants are produced, the socioeconomic status of the rural population has changed [97]. The government should motivate private gardeners to cultivate medicinal plants to ensure a constant supply. New jobs and prospects for employment would be created, contributing to economic sustainability in rural areas. For this sector to reach its full potential, we need feasible policies with a well-defined economic vision and sound planning techniques [98]. Today, encouraging the application of traditional herbal remedies is essential, as is investigating the integration of these treatments into context of public health. This potential has already been reached because India is home to abundant medicinal plants in great demand on the international market. If India wants the herbal medicine business to grow sustainably, it must fund studies into biological products, agrotechnology, standardized procedures, and quality control. To accomplish this, it is essential to comprehend the socioeconomic context and policies that promote research. Medicinal plant biodiversity must be safeguarded, and biopiracy must be stopped if this industry is to continue expanding. To demonstrate the scientific efficacy of our irreplaceable plant resources through exhaustive phytochemical, biological, and pharmacological research, collecting and documenting the extant traditional knowledge on them is necessary.

5.4 Bioeconomics

The green economy has evolved as a wholly novel idea in which industrial sectors have been forced to rethink their objectives, which are characterized by longevity and long-term viability, and focus growth on identifying new sustainable solutions [99]. In order to generate the components essential for human sustenance, this method entails using resources that can be renewed from the land and water, such as forests, crops, and microbes. It stands out as a suggestion for politicians and policymakers. Still, it has since garnered support from the general public, the research and development community, the financial community, and business leaders. The bioeconomy is more than just a branch of science or a particular industry; it is the framework for bringing together all of the significant businesses and endeavors built on bio-based products in a cutting-edge environment. Over 50 countries globally, including both developed and developing economies, now have bioeconomy strategies and initiatives in place. With the emergence of the bioeconomy, herbal medicine is becoming increasingly important to many forest-based occupations. In tropical regions, a bioeconomy transition has the potential to improve social engagement, protect and restore habitats, increase biodiversity knowledge, valorize livelihoods, and ultimately move away from the commodification of nature [99, 100]. Because it puts more pressure on natural resources and could result in overexploitation, the bioeconomy idea has been questioned until now. The emerging bioeconomy paradigm has also sparked the discussion over trade-offs between energy, food, and land. Furthermore, the bioeconomy idea has placed a strong emphasis on taking natural resources out of the environment, undermining significant benefits that ecosystems offer humans [100]. Such value chains must be assessed in order to make sure that over-exploitation is prevented and that local producers benefit from all activities, from cultivation to distribution.

5.5 Studies on Herbal Treatments

The plethora of scholarly articles that have recently been published strongly suggests that there is a growing concern among pharmacologists, microbiologists, and biochemists that botanists and natural product scientists are studying potential uses for medications for the management of multiple diseases [101, 102]. Most of these exercises focus on the isolation, purification, methodology for bioanalysis, and description of phytochemicals' pharmacological principles. In addition, research into herbal medicine aims to describe their molecular structures, mode of action, and potential toxicity [103]. In the twenty-first century, a paradigm shift is occurring in favor of standardizing herbal drugs for therapeutic purposes, resulting from search with corroborating data on herbal therapy, which numerous studies have supported and confirmed their effectiveness [104]. Concerns regarding their safety are: Ingestion of particular natural remedies has also been examined and approved using both in vivo and in vitro models [105].

Phytochemical and pharmacological studies of plants for therapeutic purposes were actively investigated throughout the past decade and conducted in universities and learning centers. Researchers are exerting considerable effort to identify and separate the bioactive chemical components, as well as to substantiate the efficacy and safety claims made about them [106]. Countless randomized clinical studies based on empirical proof have yielded favorable results in most natural remedies [107]. Understanding the mechanism of operation of plant bioactive ingredients has been facilitated by omics approaches, which has opened the way for the development and standardization of several herbal medications [108]. To contend successfully in biomedical science, it is crucial to remember that novel concepts and recent developments in the research field of herbal medicine have significantly impacted herbal remedies.

6 Recommendations for Expanding the Medicinal Plants Marketplace

An individual strategy for promoting commercial production, technological advancement, and a growth in medicinal herb exports is needed to take advantage of the current global interest in medicinal plants of Indian origin. Convergent efforts across all stages (including study findings, production, acquiring, processing, storage, manufacturing, and marketing) and an appropriate legislative framework are required to advance the medicinal plant industry. This evaluation identified several problems with the medicinal plant–based venture as well as potential solutions.

The choosing of cultivable medicinal plant species is an essential initial stage in the growth of the medicinal plant industry. The main reason for cultivating a particular medicinal plant variety is its economic viability. Additionally, according to National Planning Commission and National Medicinal Plant Boards (NMPBs), cultivation should be prioritized for rare species that cannot be eradicated from the wild because they tend to be expensive, in high demand, and are in scarce supply.

A medicinal plant may not be worth the cost to grow if it is abundant and easy to collect in the wild. Consequently, it is crucial to encourage the widespread cultivation of uncommon native varieties. Culturing medicinal plant species must be postponed until a reliable cultivation technique for the respective species is available. Numerous medicinal plant species can be grown in their natural niches in the varied climate and soil conditions of Northern India. To advance the medicinal plant industry, the following steps are required:

1. Documentation of traditional uses of medicinal plants
2. Certification of raw materials for quality control to be used in production
3. Build better agrotechnology for high-value medicinal plants
4. Indigenous systems of law should be formally recognized and protected
5. Develop a transparent procedure for issuing licenses to grow crops within a given time frame
6. Improve the methods of gathering and preparing medicinal herbs by doing continuing research and teaching

These initiatives could help rural and disadvantaged communities diversify their revenue sources and reduce their dependence on renewable resource bases [55, 59, 109, 110]. Agricultural funding organizations might help the medicinal plant industry thrive and research institutions support medicinal plant cultivators and producers by enhancing their comprehension of cultivation techniques [111]. Several variables, such as awareness among farmers and interest, beneficial policies by the government, secure and open markets, profitable prices of products, access to foundational and practical techniques, and the availability of skilled labor influence the successful cultivation of medicinal plants [112]. All of the current medical plant research must be distributed through a networked communication framework. Numerous herbs are used to treat diseases, but documentation is inadequate due to poor communication and infrequent application. Documenting the indigenous services of obscure and less-known medicinal plants is essential in order to communicate knowledge regarding their therapeutic value and relieve pressure on overfarmed species.

7 Conclusion

Herbal medicine is gaining popularity among the general population since it often does not produce any adverse reactions, has a lasting therapeutic impact on human wellness, and is frequently cost-effective even though the treatment typically lasts for a more extended period. If the information on clinical confirmation is prepared scientifically, it will not be difficult to coexist with modern medicine. The vast majority of the unprocessed ingredients (medicinal plants) utilized in the production of herbal therapeutic goods are taken from forests, which are the only environments in which these plants may thrive as a natural component of the flora. Producers of herbal medicines are required to develop the essential medicinal ingredients methodically so that they can guarantee the authenticity of the substances employed. Firms can additionally enter into buyback arrangements with the growers, in which they trade confirmed seeds and the relevant technology for a percentage of the production, and then purchase the full crop after it has been harvested. Before developing new products, the herbal business has to ensure that wild-harvested herbs are appropriately recognized and have those plants defined, maybe based on the amount of their active elements. If such provisions aren't in place, the description should be centered on the concentration level of the herbs' active ingredients. Using current biotechnological methods, the relevant government agencies ought to organize protection actions for known medicinal plants that can take place either in situ or ex situ.

During the production of medicine, "good manufacturing practices," also known as "GMP," must be utilized to guarantee the product's consistency and high quality. Regardless of the fact that these aspects have been defined in the past years via therapeutic experience, it is necessary to create clinical evidence regarding the security and efficacy of traditional herbal medicines to appeal to the contemporary mind. This must be done to win over the modern mind.

Part IV

Quality Assessment and Research Need of Herbal Medicine

Trace Metals Contamination of Herbal Remedies

48

Health Implications and Quality Control Strategies

Sylvester Chibueze Izah, Odangowei Inetiminebi Ogidi, Adams Ovie Iyiola, and Chioma Peggy Obasi

Contents

Abstract

Trace elements are ubiquitous chemical agents. They are basically classified into two categories: vital and non-vital. The vital group has a beneficial role in biological systems at certain concentrations, while the non-vital group has no known direct biological function; hence, even a low concentration of it shows

toxicity. Trace elements such as copper, zinc, magnesium, cobalt, lead, cadmium, chromium, arsenic, nickel, mercury, and iron have been detected in herbal medicine in different parts of the world. The trace metals enter the herbal medicine through the plant materials that are used in the formulation of the medicine; this could be due to the fact that plants have the tendency to bioaccumulate them in the soil. Furthermore, it could be from other materials, such as water used (for liquid herbal medicine), ingredients used in packaging them, etc. The concentration of these trace metals sometimes exceeds the tolerable level. Thereby posing a potential risk for the dysfunction of vital organs and tissues such as the skin, liver, kidney, and the various systems such as the cardiovascular, reproductive, digestive, respiratory, and nervous systems in the human body. If the disorder is not properly managed, it could lead to a chronic condition and even death. The trace contamination of herbal medicines can be avoided through quality assurance measures such as good manufacturing practices and good agricultural and collection practices for herbal medicines. Furthermore, there is a need for standardization and quality analysis at every stage of the value chain of herbal medicine, starting from the cultivation or collection of the herbs to the utilization of the formulated herbal medicine in the treatment of disease conditions.

Trace element · Health implications · Quality control · Health hazards · Chemical contaminants

1 Introduction

Trace metals are metalloids with a particular density of greater than 5 g/cm^3 having a detrimental effect on both the environment and living beings [1, 2]. Trace elements are usually characterized by high electrical conductivity, malleability, and luster and have the ability to lose their electrons to form cations. They mostly naturally occur in the crust of the earth and differ in composition between different sites, resulting in spatial variances in concentrations within a vicinity.

Trace elements have been widely reported in different environmental matrices including air [3, 4], soil [5–10], sediment [11, 12], water [1, 13–17], foods such as fishes [18–25], palm oil [26], cow meat [27], palm wine [28], tomatoes [29], vegetables [30], *Saccharomyces cerevisiae* biomass [31], waste water [32–34], spices and culinary condiments [35], and herbal medicine [36–38].

The trace metals are basically divided into two categories: essential and nonessential. The essential trace metals play a significant role in enzyme synthesis in living cells, while the nonessential metals do not have any direct biological functions. Trace metals have a permissible level of effect on human health that will cause harm when exceeded. The high level of trace metals in human health is dangerous and could result in illness, abortion, preterm labor, and mental health retardation, especially in children. It can also cause high blood pressure, fatigue, kidney problems, and brain problems in adults [1]. The concentration of trace metals can be influenced by production factors such as fertilizer, pesticide, and the food processing industry, as well as the oil and gas sector [39], mining, industrial activities, urban runoff, etc. Also, natural activities like soil erosion and the natural weathering of the earth's crust are sources of trace metals in the environment.

The accumulation of trace metals in the body has many adverse health effects if allowed to continue for a long period of time. Trace metal exposure continues and is increasing in many parts of the world. Trace metals have significant environmental effects as pollutants and toxicity problems of increasing significance for ecological, nutritional reasons [40, 41]. Some trace metals commonly found in waste water include arsenic, cadmium, chromium, copper, lead, nickel, and zinc. These metals pose risks to the environment, which in turn affects human health.

Herbal medicine is an important remedy for diseases. Approximately 80% of the global population relies on herbal medicine for the treatment of diseases, especially among individuals residing in rural areas in many parts of the developing world [42, 43]. Herbal medicines are produced using plants as active ingredients [36–38]. Thus, the use of plant parts or the combination of different plant parts to form a medicine is increasing. This herbal medicine is basically formulated in powder or liquid form using parts of medicinal plants that haven proven to possess therapeutic potentials through research and development [44–67]. The focus of this chapter is to assess the level of trace metals in herbal medicine, the composition of herbal medicine used in the treatment of human diseases, and the human health implications of trace metals in herbal medicine. The chapter concludes by highlighting the quality control strategies for trace metals in herbal medicine.

2 Overview of Contaminants of Herbal Medicine

Herbal products are usually of plant origin. The use of medicinal plants is one of the oldest methods of treating illness and is mostly used in healthcare in low- and middle-income countries around the world. Its use has increased in developed countries because it is assumed to be harmless because it is derived from natural products. Presently, safety has become a major concern in the world. Most contaminants, such as metals and radionuclides, occur naturally in the atmosphere and on the ground. Some may occur from human activities in the environment, such as chemical factories, which later bioaccumulate in medicinal plants, which are active ingredients in the formulation of herbal medicine. Some contaminants may arise from the conditions in which the medicinal plant is cultivated, treatment during postharvest, or the manufacturing of products from the medicinal plants, such as residues from pesticides and fertilizers. Despite the perceived idea that medicinal herbs are safe, their compounds can interact with synthetic drugs, and some have side effects [68, 69].

With the increased usage of herbal medicine by humans and the expansion of the markets for herbal products globally, the issue of safety has become a major focus for both the health and public sectors. Countries around the world have begun regulating their herbal products based on various standards accrued to them. The World Health

Organization [70] developed some guidelines and strategies for herbal medicines focused on promoting the safety, efficacy, and quality of herbal products and medicines. This move is apt because the quality of herbal medicines directly impacts their efficacy and safety, as the most important step is controlling the quality of medicinal plants and the materials produced from herbs. This area is complex because it cuts across different areas ranging from the condition of the environment to agricultural practices during the propagation of herbal plants.

Many contaminants and residues that have the ability to cause serious harm to humans after the consumption of trace metals have been reported [71, 72]. The majority of these contaminants occur naturally in the environment, such as radionuclides, bacteria, or toxic metals. Some may be caused by the use of some materials in the past or present that leach hazardous substances that pollute the environment and medicinal plants. Examples of such are the factories' emissions and pesticide residues. It has been reported in recent research that herbal plants can absorb trace metals during growth [73]; this implies that there is a potential risk and danger to the health and well-being of human beings. These dangers can be reduced by ensuring the herbal medicines that contain such hazardous substances and contaminants do not get to the open market. The quality of the herbal plants and products must be checked optimally before reaching the public market.

The contamination of herbal medicine is a threat that affects humans globally, especially at threshold concentrations. The uptake by plants and animals and the accumulation in the food chain are threats to animal and human health [36, 74]. The contaminants in herbal medicine can be classified into biological, chemical, physical, and radioactive contaminants (Fig. 1). Many of these contaminants can cause several disorders, affecting the internal organs and causing various types of cancer

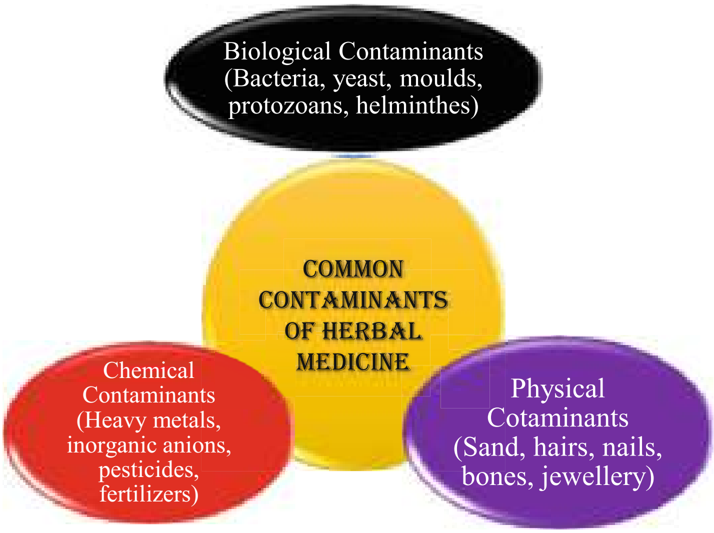

Fig. 1 Common types of contaminants of herbal medicine

depending on their toxicity level. WHO [70] reported some hazardous residues that may be present in herbal medicine, including organic solvent residues such as acetone, methanol, ethanol, and butanol, and residues from agrochemicals such as chemical fertilizers and pesticides. Some of the residues are unavoidable contaminants. For example, in most agricultural practices, the use of pesticides is increasing in order to kill, repel, or mitigate pests [75–87]. Some commonly used pesticides include fungicides, insecticides, and herbicides. Many chemical-based pesticides have the ability to persist in the environment for a long period of time. Therefore, some of the residues of the pesticides can enter the herbal medicine through the water, soil, air, and handling stages. Furthermore, traces of pesticide residues in medicine plants can be detected at different stages, including the plant itself, the production stage, and even finished products.

2.1 Common Types of Contaminants of Herbal Medicine

2.1.1 Biological Contamination

Biological contaminants are mainly life forms that can contaminate the quality of herbal medicine. The life forms can be classified into microorganisms (fungi, thus molds, yeasts, bacteria, and even viruses), parasites (protozoans and helminthes), plant residues, and animals (anthropods). Some of these contaminants, such as molds, can produce mycotoxins that are toxic to humans [88–90]. Some secondary metabolites are toxic to humans, and limits have been set for their levels in food and spices by European legislation. Limits have also been set for some medicinal herbs by the European Pharmacopoeia. The development of mycotoxin from mold depends on the following factors:

- The substrate on which the mold is growing
- The humidity of the environment
- The genetic predisposition of mold to produce mycotoxin
- The carbon dioxide to oxygen ratio
- The presence of other microbial species that are competitive and the presence of fungicides

2.1.2 Chemical Contamination

Chemical contaminants include metallic and nonmetallic toxicants such as nitrate, nitrite, arsenic, copper, mercury, cadmium, chromium, and lead; plant residues; fumigants; agrochemical residues; chemical-based pesticides; and fertilizers. This contamination may be caused by various sources; examples of such are the discharge of contaminated emissions from factories, contaminated water that runs off into rivers, lakes, and water bodies, the soil composition, and fertilizer composition.

2.1.3 Physical Contaminants

Physical contaminants are substances that can be seen with the naked eye, and they can contaminate herbal medicine. Some of the potential physical constituents of herbal medicine include sand, hair, nails, bones, jewelry, etc. The presence of foreign objects or physical contaminants may affect consumers.

3 Global Trace Metal Concentrations in Herbal Medicine

Many countries around the world, including India, Malaysia, Nigeria, the United Arab Emirates, Brazil, Ethiopia, Turkey, Ghana, China, Pakistan, Bangladesh, Iran, Poland, Zimbabwe, South Africa, Uganda, and the Sudan, have reported finding trace metals (copper, zinc, manganese, cobalt, lead, cadmium, chromium, nickel, mercury, and iron) in various herbal medicines (liquid and powder) (Table 1). The health, safety, and quality of the herbal product are among the factors that determine the global standard and regulatory criteria for the concentration of trace metals in herbal medicine. However, these legal specifications differ between nations [91]. The Italian Pharmacopoeia (FUI), the United States Pharmacopoeia (USP), and the European Pharmacopoeia (Ph. Eur.) are only a few examples of international laws on medicinal plants and products. Additionally, administrate frameworks have been developed to control the caliber of plant-based goods. Many countries have their own administrative procedures for herbal medicine or traditional medicine; however, China leads publications on medicinal plant analysis and number of inclusions in their Pharmacopoeia [92]. Before 1998, just 14 member nations, according to WHO [93], had laws governing herbal goods; by 2003, that number had risen to 53 (37%). Guidelines have been devised expressly to ensure that levels of trace metal concentration in medicinal and plant-based goods are within appropriate ranges in nations including Malaysia, Singapore, Canada, China, and Malaysia (Table 3). Although the maximum levels that are acceptable for Cadmium and Lead in raw materials are 0.3 mg/kg and 10 mg/kg, respectively [94], WHO has yet to publicize and establish these amounts.

The concentration of the reported trace metals in herbal medicine often exceeds the allowable level recommended by some countries such as Canada, China, Malaysia, Singapore, Thailand, the Republic of Korea, and the World Health Organization (Table 2). Basically, the presence of these trace metals in the herbal medicine is as a result of the traces of the metals in the plants used as active ingredients in the formulation of the herbal medicine, the water used in the formulation (in the case of liquid herbal medicine), processing equipment, and the environment.

4 Composition of Herbal Medicine Used in the Treatment of Human Diseases that Trace Metals Have Been Detected

Trace metals have been found in some herbal medicine used in the treatment of diseases conditions (Table 3), including those that cause piles, waist pains, sexual weakness, constipation, removal of excess phlegm, stomach pains, improvements in eyesight, menstrual pains, headache, infertility, body pains, high fever and toothache, menstrual pains, anemia, lumbago, dyspepsia, purifies blood, enhances

Table 3 Composition of herbal medicine used in the treatment of human diseases that trace metals have been detected

Name of the herbal medicine	Composition	Indications	List the trace metals that have been reported	Types of herbal medicine (liquid/ powdered)	Study locations and country	References
Not disclosed	*Carica papaya*, Khaya	Piles, waist pains, sexual weakness, constipation, removal of excess phlegm, stomach pains, improves eyesight, menstrual pains, headache, infertility, body pains, high fever and toothache	Iron, zinc and lead	Liquid	Accra/Ghana	[98]
Not disclosed	Combination of several medicinal plant parts and honey	Piles, menstrual pains, anemia, abdominal pain, lumbago, dyspepsia, purifies blood, enhances circulation	Zinc and lead	Liquid	Accra/Ghana	[98]
Not disclosed	Combination of several medicinal plant parts	Relief of piles, constipation, waist pains, headache, fever, sexual weakness, fibroid, hernia	Iron, zinc, cadmium, and lead	Liquid	Accra/Ghana	[98]
Not disclosed	Combination of several medicinal plant parts	Ordinary piles, bleeding piles, eyes itching, sexual weaknesses, menstrual pains, constipation, rheumatism	Iron, zinc, cadmium, and lead	Liquid	Accra/Ghana	[98]
Not disclosed	Combination of several medicinal plant parts	Rheumatism, anemia, menstrual disorder, loss of appetite, tiredness, general disability, piles, fevers	Zinc and lead	Liquid	Accra/Ghana	[98]
Not disclosed	Combination of several medicinal plant parts	Rheumatism, anemia, menstrual disorder, loss of appetite, tiredness, general disability, piles, fevers	Iron, zinc, cadmium, and lead	Liquid	Accra/Ghana	[98]

(continued)

Table 3 (continued)

Name of the herbal medicine	Composition	Indications	List the trace metals that have been reported	Types of herbal medicine (liquid/ powdered)	Study locations and country	References
Not disclosed	Combination of several medicinal plant parts	Constipation, kidney-related problems, asthma, sexual weakness, menstrual imbalances, removes phlegm, appetizer	Iron, zinc, cadmium, and lead	Liquid	Accra/Ghana	[98]
Bobofen	Combination of several medicinal plant parts at varying concentration	Spastic gastric and intestinal ailments, colic, flatulence, adjuvant treatment of inflammatory states of the alimentary tract	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Bronchial	Combination of several medicinal plant parts at varying concentration	Adjuvant in upper respiratory tracts infections, particularly in cases of dry cough and in common colds with fever	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Cholagoga II	Combination of several medicinal plant parts at varying concentration	Metabolic disorders and insufficient secretion of bile, adjuvant in biliary dyskinesia	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Circulosan	Combination of several medicinal plant parts at varying concentration	Heart ailments resulting from neurosis and in climacterium period, adjuvant in mild heart rhythm disorders, and impaired heart efficiency	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Gastrosan	Combination of several medicinal plant parts at varying concentration	Alimentary tract inflammation, chronic gastric and duodenal ulcer disease, adjuvant in secretory and motor disorders of the alimentary tract	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]

Diabetosan	Combination of several medicinal plant parts at varying concentration	In prediabetes states, in latent diabetes, in an early stage of insulin-independent diabetes, adjuvant in diabetes treated with anti-diabetes drugs	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Infektoten	Combination of several medicinal plant parts at varying concentration	Common colds, adjuvant in influenza, and infections of upper respiratory tract with fever	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Nervosan	Combination of several medicinal plants parts at varying concentration	Nervous tension, anxiety, mild neurosis or insomnia, adjuvant in nervous disorders during puberty and climacterium periods	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Nervinum	Combination of several medicinal plant parts at varying concentration	Discomfort caused by nervousness, mild tension, and anxiety, difficulties in falling asleep	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Normosan	Combination of several medicinal plant parts at varying concentration	Constipations, adjuvant in metabolic disorders and meteorism	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Pyrosan	Combination of several medicinal plant parts at varying concentration	Diaphoretic in fever states, common colds, rheumatic ailments, muscle pains, adjuvant in a flu	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Septosan	Combination of several medicinal plant parts at varying concentration	Acute and chronic inflammations of the oral cavity and throat mucosa, adjuvant in gingivitis and tonsillitis, angina, and in purulent processes of the oral cavity	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]
Urosan	Combination of several medicinal plant parts at varying concentration	An agent increasing secretion of urine in renal calculosis and urinary sand, adjuvant in	Iron, zinc, cadmium, manganese, nickel, chromium, cadmium, and lead	Liquid	Gdansk/ Poland	[136]

Table 3 (continued)

Name of the herbal medicine	Composition	Indications	List the trace metals that have been reported	Types of herbal medicine (liquid/ powdered)	Study locations and country	References
Not disclosed	Combination of several medicinal plant parts	Stomach disorder, indigestion, peptic/duodenal ulcer, improves blood circulation, eliminates pain, and discomfort	Zinc and copper	Liquid	Lagos/ Nigeria	[112]
Not disclosed	Combination of several medicinal plant parts	Pile, hemorrhoid, waist pain, enhances effective digestion, reduces fatigue, improves libido, strengthens the heart and cardiac muscles, reduces blood sugar	Zinc and copper	Liquid	Lagos/ Nigeria	[112]
Not disclosed	Combination of several medicinal plant parts	Glaucoma, eye ulcer, cataract	Zinc and copper	Liquid	Lagos/ Nigeria	[112]
Not disclosed	Combination of several medicinal plant parts	Purifies the blood, eliminates toxic material from the blood vessels, reduces accumulated fat and cholesterol level, prevents edema, numbness, and reduces blood sugar	Zinc and copper	Liquid	Lagos/ Nigeria	[112]
C-lax	Combination of several medicinal plant parts	Laxative	Cadmium and lead	Powder	Tehran/Iran	[120]
Carvil	Combination of several medicinal plant parts	Weight loss	Cadmium and lead	Powder	Tehran/Iran	[120]
Garlet	Combination of several medicinal plant parts	Antihypertensive and lipid-lowering agents	Cadmium and lead	Powder	Tehran/Iran	[120]
Slim-quick	Combination of several medicinal plant parts	Appetite suppression Obesity weight loss	Cadmium and lead	Powder	Tehran/Iran	[120]

Galega	Combination of several medicinal plant parts	Anti-diabetic	Cadmium and lead	Powder	Tehran/Iran	[120]
Valiflore	Combination of several medicinal plant parts	Sedative hypnotic	Cadmium and lead	Powder	Tehran/Iran	[120]
Garcine	*Allium sativum*	Anti-hypertensive, anti-hyperlipidemic, antithrombotic, anti-atherogenicity	Cadmium and lead	Powder	Tehran/Iran	[120]
Ginko	*Ginkgo biloba*	Enhance memory	Cadmium and lead	Powder	Tehran/Iran	[120]
Green teadin	Combination of several medicinal plant parts	Lowering cholesterol, weight loss, preventing diabetes, and stroke	Cadmium and lead	Powder	Tehran/Iran	[120]
Aphrodit	Combination of several medicinal plant parts	In potency, premature ejaculation, sexual desire disorder, and low sperm count	Cadmium and lead	Powder	Tehran/Iran	[120]
Anethum	Combination of several medicinal plant parts	Lipid-lowering agents	Cadmium and lead	Powder	Tehran/Iran	[120]
Herbal formulation	Combination of several medicinal plant parts	Treatment of hyperlipidemia	Lead	Powder	Kerala/India	[129]
Herbal tea	Combination of several medicinal plant parts	Sore throat, headache and fatigue	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Ginseng pills	American ginseng	Fatigue and blood pressure	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Ban Kah Chai	Combination of several medicinal plant parts	Stomachache and diarrhea	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Li Chee powder	Combination of several medicinal plant parts	Mild diarrhea	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Green pills	Essential oil and radix	Fever	Copper, iron, nickel and zinc	Powder	Peninsular/ Malaysia	[143]

(continued)

Table 3 (continued)

Name of the herbal medicine	Composition	Indications	List the trace metals that have been reported	Types of herbal medicine (liquid/ powdered)	Study locations and country	References
Bo Ji Wan	*Cordyceps sinensis*	Excessive sputum, cough, and cold	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Chee Ke Wan	Essential oil and radix	Diarrhea and flu	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Chee Suat Tan	Radix and gypsum	Throat ulcer	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Seng Lian cough pills	Radix and essential oil	Cough	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Intamol	Essential oil and radix	Fever	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Guan Ying Chian	Bark of "Guan Ying Chian"	Fatigue and blood pressure	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Pang Nian Jin	Bark of "Pang Nian Jin"	Fatigue and relief cold	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Cold relief pills	Rhizome Belancandae and essential oil	Cold relief	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]

Flu pills	Essential oil	Flu	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Biau Leng San	*Artemisia*, malt, and coptis	Woman stomachache	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Oh Ouh Pau Chee San medicated powder	Mentha herb and *radix angelica*	Improving appetite	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Stomachache powder	Mentha herb and *radix angelica*	Stomachache and flatulence	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Soo Hup Wan tiny pills	Essential oil and rhizome cymbopogon	Indigestion and vomiting	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Tou Seah San (baby)	*Poriacocos* and semen *Plantago asiatica*	Stomachache	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Hung Lien Shang Ching Pien	Essential oil and ginseng	Reducing heat	Copper, iron, nickel, and zinc	Powder	Peninsular/ Malaysia	[143]
Deep roots	Combination of several medicinal plant parts	Male infertility	Zinc, copper, and manganese	Liquid	Abakaliki/ Nigeria	[113]

circulation Intestinal, respiratory, and metabolic disorders, as well as discomfort brought on by nervousness, mild tension, and anxiety, problems falling asleep, constipation, diabetes, ulcers, rheumatic illnesses, body inflammations, and renal issues, can all be treated and managed with the help of cominatin, according to Suchacz and Wesolowski [136]. These conditions include ulcers, diabetes, rheumatoid arthritis, body inflammations, and renal issues. Additionally, according to Kumar et al. [144], some herbal remedies can boost vigor, lessen physical weakness, and enhance sexual performance. The management and treatment of antitussive, expectorant, peptic ulcer, gastritis, menstruation disorder, hypertension, depression, migraine, urinary issues, anxiety, and insomnia are all conditions that certain herbal medication is useful in managing and treating, according to Ravanbakhsh et al. [136]. Malaria, typhoid, painful and irregular periods, diabetes, stomach issues, piles, vaginal itchiness, burning, and irritation, chronic piles that help with digestion, hemorrhoids, and waist pain, according to Idu et al. [112] strengthens the heart and cardiac muscles, boosts libido, lowers fatigue, and increases effective digestion. Herbal medication can be used to control or treat conditions like low blood sugar, infertility, menstruation dysfunction, STDs, mouth odor, acute stomachache, obesity, glaucoma, eye ulcers, and cataracts. The use of herbal medicine in the treatment of urinary illness, as a fertility enhancer, and in stabilizing menstrual cycles was also described by Udom et al. [140]. According to Mousavi et al. [120], certain herbal remedies have been shown to improve memory, lower cholesterol, prevent diabetes, prevent stroke, and be anti-hypertensive, anti-hypertensive, anti-hyperlipidemic, antithrombotic, anti-atherogenicity, and lipid-lowering agents. They also act as laxatives and aid in weight loss. According to Yap et al. [143], male infertility, diarrhea, copious sputum, cough, and cold.

5 Human Health Implications of Trace Metals

Trace metals are fundamentally divided into vital and non-vital groups based on their biological impacts. Iron, zinc, copper, chromium, cobalt, and manganese are typical examples of vital trace metals for human health and may be excellent for the body's metabolism [145, 146]. The non-vital trace metals, including cadmium, lead, and mercury, are regularly found in the environmental matrices and food sources of humans, just like the essential ones. Thus, the typical method of taking trace metals into the body is through the dermal route, inhalation, and, most importantly, ingestion of foods, drugs, or materials containing traces of these metals. However, the organs and tissues of the body may suffer if the concentration surpasses the permissible limit. Some of the typical roles of the essential metals are shown in Table 4.

Life support requires medicine, and herbal medicines contain trace metals that are detrimental to humans. Globally, herbal medicines have been reported to contain traces of toxic metals (Table 1). Trace metals often turn toxic when their concentration exceeds the permissible limit. In many developing nations, herbal medicine is one of the key resources for maintaining a healthy lifestyle. The majority of herbal medicines contain trace metal concentrations above allowable limits.

Table 4 Functions of vital trace metals to the human body

Essential trace metal	Roles	References
Iron	Involved in a number of biochemical and metabolic activities, including the transport of oxygen, the synthesis of deoxyribonucleic acid, the electron transport chain, and the control of cell development and differentiation	[147–149]
	Involved in some physiological processes, as well as the production of iron-containing enzymes and hemoglobin	[150]
Zinc	Vital for the generation of prostaglandins, bone mineralization, healthy thyroid function, taste acuity, blood coagulation, and maintaining sperm quality	[151]
	Vital for the immune system and wound healing	[146, 151, 152]
	It is necessary for connective tissue growth and maintenance, homeostasis, DNA synthesis, RNA transcription, cell division, and cell activation	[151, 152]
	Important structural, co-structural, catalytic, and regulatory capacities in enzyme molecules	[151–154]
	Essential for taste acuity, prostaglandin production, bone mineralization, proper thyroid function, blood clotting, cognitive functions, fetal growth, and sperm production	[146]
	Control of body fluid pH, production of collagen for hair and nail growth, improvement of cerebral development, and enhancement of sexual processes like testosterone secretion and prostate activity	[151, 155]
	Important for healthy organogenesis, neurotransmitter function, thymus development, taste sensibility epithelialization, pancreatic and gastric enzyme secretion, proper spermatogenesis and maturation, and sperm genomic integrity	[146, 156]
Copper	The production of red blood cells (hemoglobin), connective tissue metabolism, and bone growth are all examples of normal iron metabolism	[146, 152, 157]
	Numerous enzymes, including tyrosinase, uricase, and cytochrome oxidase, are involved in cell metabolism	[146]
	Important for several biological operations, such as hepatocyte and brain functioning, mitochondrial respiration, regulating hemoglobin levels, and embryonic growth	[158]
	Essential as a pro-oxidant, antioxidant, and for maintaining the strength of the skin, blood vessels, epithelium, myelin, and the thyroid gland	[152]
Manganese	Part of metalloenzymes and as a need for enzyme activation	[146]
	A need for the metabolism of mucopolysaccharides, fatty acids, and cholesterol	[146, 159]
Cobalt	It regulates the translocation of enzymes like homocysteine methyltransferase during the metabolism of methionine.	[146]
Chromium	Glucose tolerance factor biosynthesis	[146]

Adapted from Izah et al. [1]

The human body can create dangerous free radicals that can damage cells even at the cellular level when the amounts of trace metals in ingestible materials surpass optimal limits. These free radicals can cause diseases like cancer, harm to the immune system and central nervous system, damage to the intestinal tract, and harm to the lungs, kidneys, liver, and other vital organs. Additional acute human health symptoms include skin rashes, vomiting, dizziness, unexpected birth outcomes, and occasionally even death due to the intake of high concentrations of trace minerals by humans. Redox-active metals may also undergo redox cycling events because of their ability to produce reactive radicals like the superoxide anion radical and nitric oxide in biological systems [1]. According to Jomova and Valko [160], high levels of trace metals are linked to a wide range of different disorders, including cancer, cardiovascular disease, diabetes, atherosclerosis, neurological issues, and chronic inflammation. In addition, trace metal toxicity can cause muscle cramps, nausea, lethargy, poor nutrition, vomiting, pain, sweating, migraines, suffocation, speech difficulty, convulsions, anxiety, emotional instability, insomnia, and nausea. There is also a probability of digestive system problems as a result of exposure to trace metal-contaminated food, water [1], and herbal medicine. According to Rowel [161], exposure to trace metals such as lead, mercury, copper, cadmium, and chromium can cause cardiovascular disease, some types of cancer, and developmental issues in children, in addition to neurological effects like memory loss and behavioral changes.

Furthermore, trace metals are harmful to the human body because they can accumulate inside the body and result in deadly problems even in low quantities. These effects might be teratogenic, phytotoxic, carcinogenic, or synergistic. Trace metal concentrations can also harm cell membranes by interfering with cytoplasmic and nuclear functions [1]. According to Oguntona et al. [162], it could take months or even years for the chronic symptoms of trace metal exposure to manifest. Table 5 provides a list of the harmful consequences that trace metals in drinking water have on human health.

Arsenic is another nonessential metals that have been reported in food, water, and herbal medicine. High levels of arsenic exposure may result in cancer, dermatitis, neurological, pulmonary, gastrointestinal, cardiovascular, hematological, and neurological issues (Fig. 2) [163].

6 Quality Control Strategies of Trace Metals in Herbal Medicine

Quality control is the process involved in the standardization of an herbal product, drug, preparation, or substance. Quality control results in the standardization of herbal medicine and products. The authenticity of the herbal product is determined by morphological and microscopic identification, and the quality is determined by the physical and chemical characteristics based on the existing quality standards [187].

Table 5 Pathological effect of trace metal on human health

Metals	Pathological effects/symptoms	References
Lead	Liver and brain damage, infertility in women, and death.	[164, 165]
	Destruction to reproductive system	[165–167]
	Destruction to kidney	[164, 165, 167, 168, 169, 170]
	Destruction to nervous system	[164, 165, 166, 167, 170, 171]
	Birth weight loss and early birth	[172]
	High concentration results in anemia and brain edema	[168]
	Destruction or poisoning of cardiovascular system	[166, 173]
	Hair loss, lung fibrosis, skin allergies, an eczema flare-up, and varying kidney function	[172]
	Destruction to renal system	[166, 174]
	Anorexia, headache, malaise, diarrhea, lead-palsy, encephalopathy, and sleeplessness are among the symptoms of a gastrointestinal and neuromuscular illness	[174]
	Causes anemia, elevated blood pressure, and numbness in the fingers, wrists, or ankles	[164]
	Brain development is hampered, and the immune system is suppressed	[169]
Chromium	The oxidation of blood cells causes hemolysis and renal problems	[171]
	Injuries to the kidneys, liver	[164, 175]
	Circulatory, nervous system, and skin irritation issues	[175]
	Numerous health conditions, such as cancer, rapid breathing, irritation of the nasal mucosa, nose ulcers, runny noses, and breathing issues include asthma, coughing, and shortness of breath	[164]
	Cancer	[170]
Cadmium	Desmineralization of the bones, kidney, and liver damage	[164, 167, 170, 171, 174, 176, 177]
	Breathing issues and internal bleeding	[174]
Cobalt	Raises the likelihood of goiter	[168]
	Nauseousness and vomiting, cardiovascular, thyroid, and optical impairment	[178]
Manganese	Hinder dietary iron absorption, which can lead to iron deficient anemia	[179]
	Neurological condition	[170]
Copper	Abdominal pains, nausea, vomiting, diarrhea, headache, and dizziness	[180]
	Anemia, acne, adrenal insufficiency and hyperactivity, allergies, hair loss, rheumatoid arthritis, cancer, raised cholesterol, depression, diabetes, dyslexia, failure to thrive, exhaustion, fears, bone fractures, headaches, heart attacks, hyperactivity, hypertension, infections, inflammation, kidney and liver dysfunction, panic attacks, strokes, and decay in teeth	[164, 175]

(continued)

Table 5 (continued)

Metals	Pathological effects/symptoms	References
	Gastrointestinal malady	[170]
Zinc	Diarrhea	[181]
Iron	Metabolic and genetic illnesses	[182]
	Siderosis, a benign form of pneumoconiosis	[164]
Mercury	Death and respiratory failure harm the developing fetus and brain. The list of symptoms also includes nervousness, tremors, abnormalities in vision or hearing, memory issues, nausea, vomiting, and diarrhea, as well as elevated blood pressure, skin rashes, and itchy eyes	[163]
	Renal and central nervous system impairment	[164, 170]
	Abnormalities of the digestive system, irritation of the respiratory tract, collapse of the kidneys, and neurotoxicity	[169]
Nickel	Carcinogenic and toxic	[167, 170]
	Digestive issues, cardiovascular illness, pulmonary fibrosis, skin dermatitis, and kidney and lung dysfunction	[183–185]
	Agents that are carcinogenic, genotoxic, genotoxic, reproductively toxic, pulmonary toxic, nephrotoxic, and toxic to the kidneys and liver	[186]

The increase in adulteration, substitution, and the inadequacy of skilled personnel are the reasons for substandard herbal medicines. There is a need for advanced quality control processes and suitable standards for herbal medicine practices and use. Standardization is a major approach used in the identification of quality, purity, and confirmation of herbal products. As the primary method of identification, physical, chemical, and biological properties can contribute to the extent of purity of herbs. For the quality preservation of natural herbs and products, quality control is necessary.

Quality is of major concern to humans, and when herbal medicines are consumed, it is important that they address the well-being of humans. As there are various quality standards for pharmaceuticals, it is important that herbal medicine follow suit and be controlled as it is for chemically synthesized medicines [188]. Standardization and investigation of phytochemicals are usually done before the production of herbal medicine [189]. However, in many parts of the world this is not carried out.

The World Health Organization has been up to the task of fighting against contaminated herbal drugs and products and has developed documents and technical guidelines to ensure the quality and safety of herbal medicine, plants, and materials. Examples of such are:

- Guidelines on good agricultural and collection practices for medicinal plants.
- Quality control measures for medicinal plant materials.

The documents have provided explicit information on the determination of chemical, biological, pesticide residues, and radionuclear contaminants that may be present in herbal medicine and medicinal plants. They also provide information on appropriate test methods for contaminants and the regional quality specification standards for contaminants and residues that may be present in herbal plants and herbal medicine. It is also essential that these guidelines be reviewed from time to time in relation to the changing environment and human activities. Medicinal plants and materials that have medicinal potential can be consumed as a dietary supplement, as food, or as functional foods. A survey by World Health Organization [93] on the national policy and regulation of herbal medicines reported that the status, based on regulation that is ascribed mostly to herbal medicine, is as dietary supplements and health foods in over 100 countries. Therefore, more work is needed in the aspect of food safety, especially in connection with herbal medicines. This approach initiated a joint collaboration between traditional medicine and food safety teams with the Food and Agriculture Organization of the United Nations and the World Health Organization Joint Programme: Codex Alimentarius [70].

The processes involved in the registration and regulation of herbal medicine and its use vary from one country to another. In areas where they are regulated, herbal medicines are classified as prescription or nonprescription medicines. The World Health Assembly at its 56th session adopted a resolution on traditional medicine (WHA56.31), which urged member states to ensure safety, quality, and national standards for herbal medicines. It requested support from the Director-General of the World Health Organization in terms of technical information for monitoring and ensuring herbal medicine quality, safety, preparation, and information exchange.

Contamination in herbal medicine should be avoided as much as possible, and this can be achieved through quality assurance measures such as good manufacturing practices and good agricultural and collection practices for herbal medicines. The concentration of these contaminants may also reduce as a result of postharvest processing in herbal extracts and finished medicinal products during the manufacturing process.

To ensure guaranteed safety in the use of herbal medicines, several studies have been carried out in some countries of the world with the aim of safeguarding the concentration of trace metals. Most of these studies used a limited number of herbal samples and categories. Due to the hazardous effects trace metals can cause on the health of humans and the environment, some approaches were carried out by researchers to show that the concentration of trace metals in herbal medicines has a potential risk to human health and requires immediate attention [190]. Some of the approaches are:

- The exposure risk assessment [36].
- The hazard quotient [36].

Studies by Izah et al. [36] on the health risk assessment of trace metals due to the usage of certain herbal medicines could affect the health of humans negatively over a prolonged period of time. With this in mind, it is very important to carry out a risk assessment of trace metals in herbal medicine to ascertain their toxicity level. Many trace metals have no known biological function. Hence, even a low concentration of it suggests toxicity. Therefore, it is vital to check for any potential source of trace metals in the herbal medicine.

Compliance with guidelines on good agricultural and collection practices for medicinal plants and quality control measures for medicinal plant materials is essential in the production of herbal medicines that are of good quality. It is essential that the guidelines be strictly followed, from the cultivation of herbal plants to the sale of the herbal product. Foreign items found in medicinal plants and herbal drugs must be within the limits set by national or international regulations. Examples of such foreign items include insects, animal dungs, and other plant species.

The maximum concentration of trace metals in herbal medicine can be given based on the provisional tolerable intake values, which can vary from country to country. Herbal medicine products are not expected to contribute to the exposure of trace metal contaminants, and it is recommended that the contamination of trace metals be minimized. For global trade, it is essential to harmonize the limits of toxic metals and their standards in herbal medicine.

7 Conclusion

Traces of chemical substances are present everywhere. They fundamentally fall into two categories: vital and non-vital. The vital group has a beneficial impact on biological systems at specified concentrations, in contrast to the non-vital group, which has no recognized direct biological role and is toxic even at low quantities. Many regions of the world have reported finding trace levels of metals in herbal treatments, including copper, zinc, magnesium, cobalt, lead, cadmium, chromium, arsenic, nickel, mercury, and iron. Plant components used in the manufacture of herbal medicines may contain trace metals since plants have a tendency to bioaccumulate these substances in the soil. It could also originate from other substances, such as the chemicals used to package herbal medicines or the water required to create their liquid form. The concentration of certain trace elements sometimes goes over the permissible limit. As a result, there is a postnatal risk for dysfunction of the body's multiple systems, such as the skin, liver, and kidney, as well as the cardiovascular, reproductive, digestive, respiratory, and neurological systems. If the issue is not properly addressed, it could become a chronic sickness and cause death. Trace contamination of herbal drugs can be avoided through quality control measures such as adequate manufacturing practices and acceptable agriculture and gathering practices. Standardization and quality assessment are necessary at every stage of the value chain for herbal medicine, from the collection or cultivation of the herbs through the use of the prepared herbal medication to treat medical ailments.

Matthew Chidozie Ogwu

Contents

Abstract

The absence of any form of a globally recognized and standardized regulation and policy for the coordination of the earliest form of medical care continues to hamper the development of this ageless and invaluable medical practice – herbal or traditional medicine. Considering that the availability, value, exploitation, exploration, and exportation of herbal medicine keep growing, this may be the

best time to promote the safety, quality, and quantity evaluation as well as efficacy of herbal medicine products, practices, and practitioners through globally recognized regulations and integration into mainstream medicine. Existing community, national, and regional guidelines can serve as foundation materials for global policymaking and regulatory parameters as this continues to be the backbone of the calls from the World Health Organization. The advantage of this approach is connected to the prevention of communities, countries, and regions in the Global South (where herbal medicine use is widespread) and elsewhere from perceiving herbal medicine regulations and policies as entirely foreign, colonial, and disconnected from current realities. However, formal structures and institutions would be required to address and understand the transdisciplinary nature, complexities, and epistemology needed to dissect the cultural, clinical, and accessibility nexus of herbal medicine policy and regulation dimensions. The direct benefits of herbal medicine regulations and policy includes an increase in coordination and One Health security while preventing misappropriation. Current loopholes in community-, regional, and national-based herbal medicine regulations and policies are encouraging quack approaches like indiscriminate and unstandardized harvesting and processing of plants with herbal medicine potentials for herbal medicine formulation as well as herbal medicine production, storage, and use in the management and treatment of diverse ailments. Therefore, unified regulations and policies would serve as a reform tool with allowance for regular updates. However, such regulations and policies would first have to overcome the challenges associated with the diverse number of plants used in herbal medicine, their phytochemical constituent, production systems, and utilization patterns.

1 Introduction

Herbal medicine has been used by humans for millennia for the treatment, management, and prevention of diseases as well as for health promotion and quality of life enhancement. The practice and products may be considered cosmopolitan despite only a little influence of globalization and the abandonment due to modern medicine. The use of herbal medicine in modern medicine has increased over time [51, 52, 58, 93]. For instance, around 80% of the global population now rely on herbal medicine for their primary healthcare, while 25% of drugs from contemporary medicine are made from plants [22, 90]. Herbal medicine is part of the heritage of almost all human communities, cultures, and traditions [75]. Herbal medicine has been practiced and utilized as the oldest treatment type in developed and developing nations [41, 60]. The World Health Organization (WHO) classified herbal medicine into three categories: raw plant materials, processed plant materials, and therapeutic herbal products [39, 88]. For many millions of people, herbal medications and traditional practitioners constitute the main source of healthcare and, in some cases, the only option [95]. This is because nature provides humans with food, clothing, housing, and medical needs. Herbal medicine practitioners could tell active plants from harmful ones and useful herbs with positive effects [41]. For nearly 80% of the world's population today, particularly in underdeveloped nations, herbal medicine remains the primary form of healthcare [38, 41, 46, 51, 63, 93]. Additionally, more people in rich countries like Germany, France, Italy, the United Kingdom, Spain, and the United States use herbs instead of regular drugs [19, 20, 90].

The procedures of herbal medicine are the culmination of centuries worth of therapeutic experience from previous generations of conventional doctors [51]. The concern of many scholars is that not all herbal medicines are safe; however, the many years of using herbal medicines provide enduring and time-tested modes of selection, preparing, and applying these herbs to address numerous health needs [4, 21, 22, 61, 62]. Due to their great safety compared to other therapeutic classes, herbal medications exhibit advantages in clinical therapies, particularly for cancer, hypertension, and many other incurable disorders [2, 28, 31, 45]. Several epidemic diseases have benefited greatly from the use of herbal remedies for both prevention and therapy [98]. For instance, in 2003, severe acute respiratory syndrome was treated using herbal medications, and the results were remarkably positive [47]. Additionally, the use of herbal remedies for the treatment of malaria finally led to the development of artemisinin, a herbal extract that is now a component of the worldwide standard treatment for *Plasmodium falciparum* welch malaria [82]. Furthermore, using herbal medicines therapy against coronavirus disease 2019 (COVID-19) is still a cost-effective solution in many nations and areas due to their efficacy, safety profile, and relatively reduced pharmaceutical costs [98].

Despite the perceived difficulties in regulating traditional, complementary/alternative, and herbal medicines on a global scale, nations have independently achieved significant progress in this area [4]. Since WHO adopted the Alma-Ata Declaration in 1978, to make primary care the key to healthcare and service for all, efforts have consistently been made to integrate traditional medicine into public health services [75]. Although existing herbal medicine policies and laws/regulations differ from country to country and region to region, they essentially continue to address the need for a global framework to ensure the safe use and practice of herbal medicines [4]. However, the differences in cultural orientation regarding the use and regulation of herbal medicines among different countries effectively reduced the opportunities to use herbal medicines to treat COVID-19 currently [98].

This chapter aims to address the need for standardized global regulations and policies for herbal medicine practice and practitioners. The chapter discusses the state of herbal medicine by highlighting available resources and the broad focus of the practice and practitioners. Thereafter, the chapter presents a viable guide for regulation and policy development through approaches, processes, and necessary tools. This is connected to the next section on the benefits of herbal medicine governance and an analysis of existing medical regulations and policies that may be relevant to herbal medicine practice and practitioners. The focus of the final part of the chapter is on the importance of sustainable regulations and policies for herbal medicine practice and practitioners.

2 State of Herbal Medicine: Resources, Practices, and Practitioners

Medicinal plants (i.e., plants that contain bioactive substances with therapeutic benefits [76]) are the core herbal medicine resources. These plants or their parts are used wholly or combined with other plants and chemicals (like water, alcohol, or soda) and used for disease prevention and health promotion through diverse strategies and are worth billions of USD per annum. Indigenous medicinal plants have long been used to cure varying diseases globally. The application of herbal medicinal plants as efficacious natural remedies in the treatment of diseases has gained prominence in recent decades as they have been recognized to pose relatively lower side effects as compared to chemical and synthetic medicines [53] and are also recognized to have widespread accessibility as compared to allopathic medicine [3, 56, 57, 66, 77]. Calixto [14] established that an estimated 40% of medicinal products used in recent times emanate from natural products (plants 25%, microorganisms (13%), and animals (3%)). Today, herbal medicine includes the use of herbs, herbal preparations, herbal materials, and finished herbal products containing active ingredients from plants, parts of plants, and other plant materials or combinations [94]. These materials are used in pursuit of Goal 3 of the United Nations Sustainable Development Goals to ensure healthy lives and promote the well-being of the world's populace.

There is widespread reportage on the use of herbal medicine globally. High patronage of herbal medicine uptake has been found in Southeast Asia. For instance, Cai et al. [12] discovered that over 1000 Chinese people use herbal drugs daily following prescriptions by Chinese medical practitioners with an annual uptake of herbal medicine clinching 200 million accounting for more than 40% of healthcare deliveries in the country [10]. Similarly, an estimated 70% of Japanese allopathic medical practitioners prescribe varying herbal and alternative treatments for their patients. Traditional Korean medicine usage is also pegged at 70% [11]. Interestingly, a nationwide survey by Rashrash et al. in 2015 in the United States found about 35% uptake of herbal supplements by adults on a routine basis [72]. The global market for herbal medicine was estimated at USD 71.19 billion in 2016 in a study conducted by Hexa Research [34], which has been projected to reach a whopping USD 5 trillion by the WHO [74]. In most developing economies, native healers are the focal health providers for the teeming populations. The implications for the preponderance of the native healers mean there is a better patient-to-healer ratio than the case of doctors-to-patient ratio in the case of allopathic medical practices.

There are peculiarities among practitioners of herbal medicine in Africa. In Ghana, herbal medicine is frequently used as the first line of defense against illness, particularly in rural areas. Traditional healers are widely used for several reasons, including the cost of care, lack of access to medical institutions, and poor roads and infrastructure. In addition, the patient-to-doctor ratio for conventional healers is 1: 200 as opposed to the approximately 1:20,000 ratio for medical practitioners. This has a significant impact on how healthcare decisions are made. Other determining elements, like economic position, level of education, and recommendations from relatives and peers, affect the type of health care a person chooses (Tabi et al. 2006; [59]). Herbal medicine is still widely recognized even though allopathic medicine has been embraced. It is a popular belief among some Akan communities in Ghana and other indigenous communities around Africa and Asia that individual(s) or an entire community may be at risk of severe illness or plague due to disobedience of native laws, customs, and culture that constitute a taboo [29, 32, 33], which is a fundamental architecture of African traditional religion. In Zambia, complicated treatment practices are often initiated following the diagnosis of a health condition by using herbal components accompanied by rituals in an attempt to cure the disease. Persistent illnesses call for *chizimba*, which means permanently locking a disease or illness away.

To do this, a lizard must be killed, and its heart must be burned with charcoal and the roots of particular trees. The combination is applied to small wounds made on the affected area. There are several ways in which herbal medicines are applied. For instance, a single plant can be used for herbal treatment or it may be used in conjunction with other plants. In whichever way the treatment is done, the acquisition, preparation, and utilization of the herbal medicines go through a similar procedure. The requisite parts of the plant are initially collected while fresh. These are then dried either at room temperature or in the open sun. Thereafter, depending on the mode of application or utilization, the dried parts of the plant are either soaked in water or other edible liquids, ground into powder form, or incompletely burned to obtain the residue for utilization. The modes of application also range from drinking the solution, adding the powder to meals, making incisions on specific parts of the human body and the powder then applied, bathing the extracts of the herbs, utilizing the steam from the boiling herbs, as well as dancing after applying the herbs to exorcise spirits. All these forms of treatment using herbal medicines are available to the ethnic groups in Zambia. Nga:nga is the name of the traditional healer in Zambia [79]. In South Africa, traditional medicine is a daily part of the lives of thousands of people. In actuality, the use of traditional medicines, often known as muti, is reported to be at 80% of the population. The term “muti,” which is derived from the words “medicinal plant,” designates drugs that are traditionally obtained from plants, minerals, and animals. Traditional medicine could also comprise minerals and animal parts in addition to plants.

A myriad of practices are also employed by traditional and herbal practitioners in the diagnosis and treatment of diseases. One dominant practice in herbal and traditional medical practice by indigenous people is divination. Divination is the practice of learning about healing via the use of symbolism that is placed at random to acquire knowledge about a person or sickness condition. In addition, it is viewed as a way to gain access to knowledge that is generally outside the scope of the rational intellect. It is a transpersonal technique wherein diviners converse with spiritual beings like gods, spirits, and ancestors to get knowledge [65]. Therefore, divination plays a crucial role in the traditional African method of disease diagnosis. The etiology of illnesses and diseases is said to be ascertainable through divination, particularly when one is suspected of breaking a taboo or contaminated by evil spirits as the source of the ailment. This is demonstrated by using cowry shells, throwing coins, seeds, dice, domino-shaped objects, or even actual dominoes, and other tools chosen by the diviner and the spirit to represent specific polarities on leather strips or flat pieces of wood. The majority of the items are divining bones, such as those from crocodiles, wild pigs, goats, antelopes, baboons, hyenas, anteaters, and lions. The bones are a representation of the forces that threaten any human being irrespective of his or her cultural orientation [16].

In herbal and traditional medical practice, interviewing and medical reporting are also a basis for the diagnosis and treatment of a health condition. Some traditional healers often rely on oral interviews to learn more about a patient’s medical history, where they have had treatment, and how long they have had the ailment which serves as the basis for finding the cure to a particular disease. Sometimes, to establish the history of the ailment, a family member could be interviewed if the patient is too ill to talk. After the interaction with the patient, the healers sometimes would advocate for the patient to access orthodox medical services for precise diagnosis. Patients are advised to return to the herbalist with the diagnosis for them to holistically heal them. The medical diagnosis of the patients is kept by the herbalist as evidence of their prowess in healing those ailments. Besides the cost of treatments which is often moderate and the easy access and availability of the herbalists, among other merits, the herbalists adopt a holistic approach to healing that involves the psychosomatic aspects of the person. Hence, there is no distinction between the natural and the spiritual or physical and the supernatural aspects of the person [80].

3 Regulation and Policy Development Approaches, Processes, and Tools

In parts of the world where the populace does not rely on herbal medicines and practitioners for their primary healthcare like in the European Union, United States, and Canada, herbal medicines are sold as food supplements albeit without or with little regulations [13]. Due to the contamination and adulteration of herbal medicinal products during their initial periods of discovery as having the capacity to treat various diseases [71], economies across the globe have enacted some guidelines and regulations to ensure the purity of these medicines to avoid complications after usage. The World Health Organization (WHO) in 2018 reported that about 90% of its member countries had some form of regulation or policy guideline on herbal medicine [94]. These regulations ensure herbal medicines are taken through some quality check and standardization processes such as physicochemical evaluation of medicinal products in their raw state through stability assessment to ensure the safety of processed products for consumption (Riedl et al. 2015).

Standardization of herbal medicines has been a complex phenomenon that involves a series of processes aimed at ensuring the quality of the final product. Given the different definitions of herbal medicines by various countries, standardization has for some time been at the individual country level. However, WHO has set guidelines lines for the standardization of herbal medicines [99]. The need for standardization has also been indicated by several studies [7, 23, 25, 30, 78, 84–86].

The first Herbal medicine strategy to be developed by the WHO was initiated between 2002 and 2005. However, due to the rapid expansion and the rapid utilization of traditional and herbal medicine, there was a shift in the reliance on herbal products which led to the incorporation of practices and practitioners in the traditional and herbal medicine fraternity stimulating the WHO to devise a comprehensive strategy which led to the development of the Traditional Medicine Strategy, 2014–2023, to regulate herbal medicine practices [95]. Three policy objectives underlie this strategic initiative. These include the building of a knowledge base that will allow for effective management of traditional and allopathic medicine within the national policy context. This is to help ensure the coordination and harmonization of the diversity of products, practitioners, and practices underlying herbal medicine. In addition, the 2014–2023 policy strategy seeks to strengthen the quality levels, safety, and right application or usage of both traditional and allopathic medicinal end products by regulating these as well as the activities of the practitioners. And finally, the policy strategy sought to make health coverage accessible to all through the integration of traditional and complementary medical service delivery as well as self-healthcare services.

There are however difficulties in the harmonization of global herbal medicine policies as different countries pursue varied regulatory strategies and implement varied policy legislations. This notwithstanding, there are several legislative frameworks on herbal products in many countries worldwide. For instance, in Mexico, legislation on herbal medicine has been incorporated into the Mexican General Health Law [73]. The Federal Commission for the Protection against Health Risks

(COFEPRIS) is a decentralized organization of the Ministry of Health charged with the responsibility of managing and promoting healthcare (COFEPRIS 2022) as enshrined in the General Health Law [73] and other legislative instruments. It sets the parameters for checking the safety and consumability of medical products including those generated from plant materials. In Canada, a whopping 1.7 million people identify themselves as indigenous and are often referred to as First Nation People [73]. Canada originated the policy of Natural Health Products (NHPs) in 1999 and incorporated herbal medicinal practices into its health system. This policy came into fruition in 2004 after the annexation of the NHPs in subsection 30(1) of the Food and Drugs Act [73]. These have legislative backing in the current national policy and national program on traditional and complementary medicine whose implementation is the reserve of provincial states and territories.

The Health Products and Health Branch of Food Canada have direct legislative authority over herbal products and as such ensure the licensing of all herbal medicine to ensure compliance with safety protocols before they are been commissioned into the market [37]. Herbal medicine products and raw materials are also sold in the market in developing countries [54, 55, 67]. In the case of the United States, there are institutions like the Food and Drug Administration (FDA), which, among other functions, is tasked with the responsibility of regulating the safety, effectiveness, as well as security of drugs, biological products, and food supplements. This implies that it has the mandate to regulate herbal medicinal products [83]. Amid these efforts at regulating herbal medicines, the United States is yet to develop a national plan that promotes the integration of herbal and complementary medicine into the healthcare system. There is, however, a National Center for Complementary and Integrative Health focused on supporting research as well as the provision of relevant information on complementary health products and practices [94].

African governments have also implemented policies and regulations aimed at regulating herbal and complementary medicines. For instance, in Kenya, a national policy document on traditional medicine and medicinal plants was drafted in 2005 which emphasizes the need to take account of all medicinal plants in the country while also establishing herbal gardens to ensure bio-conservation and also intensify research [64]. Similarly, in Ghana, many administrations have acknowledged the value of conventional medicine. This is demonstrated by the founding of the Ghana Psychic and Traditional Healers Association in 1961 and the Centre for Scientific Research into Plant Medicine in 1975. The establishment of the Food and Drugs Board in 1992, which among other things certified the sale of traditional medicine products to the general public, followed the establishment of the unit for the coordination of traditional medicine (which is now the Traditional and Alternative Medicine Directorate) in 1991 (Ministry of Health 2005). The TMPC Act, Act 575 was passed by the government in 2000 to create the Traditional Medicine Council, which is in charge of registering all Traditional Medical Practitioners in the nation. This, therefore, stands to reason that herbal medicine usage is now gaining moment, thus generating interest from international bodies and national governments to design legislative backing for traditional and complementary medicinal products.

4 Benefits of Herbal Medicine Governance

Public health and safety, job and income security, and biodiversity and resource management are major issues connected to herbal medicine. The focus of herbal medicine governance is to ensure that safe and quality herbal medicine products are available in the market to contribute to public health [18, 22]. The governance of herbal medicine will also ensure the sustainable harvesting and processing of materials used in formulating herbal medicine products and the job and income security of practitioners. Herbal medicine cannot be dissociated from allopathic medical delivery because a quality healthcare system and services are only achievable through informed policy and strategies. There is clinical trial data that abound stressing the efficacy of herbal medicine as well as herbal product components that are used in the manufacture of modern drugs. Herbal extracts are more clinically effective and accessible with fewer health risks [50, 81]. Sufficient examples have been published by clinical laboratory scientists demonstrating the potency of allopathic drugs that have been derived from herbal medicines (e.g., artemisinin) which saves millions of lives annually [26, 35]. Besides the modern governance approach, traditional governance approaches and systems may be instituted to regulate the herbal medicine sector because they shape the belief systems behind the practice and of practitioners [15]. On the other hand, modern governance systems within local spheres are considered top to be a form of downregulation and disconnected from realities. Negative experiences in the hands of modern medicine are one of the major reasons why many people prefer herbal medicine for their primary healthcare [91]. The major benefits associated with the governance of health practices as outlined in Busse et al. [8] include:

1. Providing clarity on the meaning of quality care and its connection to the health system
2. Creating a framework to assure and improve the quality of care provided by the health system
3. Evaluating care approaches based on current practices to align with cost-effectiveness and implementation
4. Addressing gaps by measuring and synthesizing existing quality healthcare knowledge and practice
5. Aligning national strategies with international guidance on quality healthcare provision
6. Ensuring accessible systems exist for an evidence-based assessment of quality healthcare strategies that address patient safety and culture
7. Clarifying the links and roles of stakeholders in assuring quality healthcare

Quality healthcare is central to the governance of every healthcare system because it links service delivery, healthcare workers, information, health products, financing, and governance to the goals, i.e., improved health, responsiveness, equity, and efficiency [9].

Fig. 1 Countries with national herbal medicine laws or regulations. (Source: adapted from WHO [94])

As of 2018, the number of countries with some form of a legal framework for herbal medicine is presented in Fig. 1. Surprisingly countries in the Global South with a long history of herbal medicine practice, production, administration, and use do not have any form of a legal framework for herbal medicine including Chad, Central Africa Republic, South Africa, Somalia, Eritrea, Congo, Gabon, Equatorial Guinea, Ivory Coast, Panama, Honduras, and Senegal.

Most of the existing national regulations are focused on prescription, nonprescription, and herbal medicines which include those that can only be purchased with a prescription from a physician, without a prescription for self-medication, and sold over-the-counter herbal drugs respectively (WHO [94]; Fig. 2).

According to WHO [94] out of the 249 member countries, 124 have some form of laws or regulation focused on herbal medicines, while 125 only have herbal medicine registration systems. Some of these are presented in Table 1.

These policies range from those that are partially or completely similar to conventional pharmaceuticals to those that are exclusive to herbal medicines. And in terms of their distribution by region, Europe and Africa dominate with 45 and 20 WHO member states with herbal medicine regulations, respectively, while Southeast Asia region had the lowest with only 10 WHO member states having herbal medicine policies as of 2018 (Figs. 3 and 4).

According to WHO [94], there is a clear increase in the number of countries with some form of herbal medicine laws and regulations from 65 in 1999 to 124 in 2018 (Figs. 3 and 5).

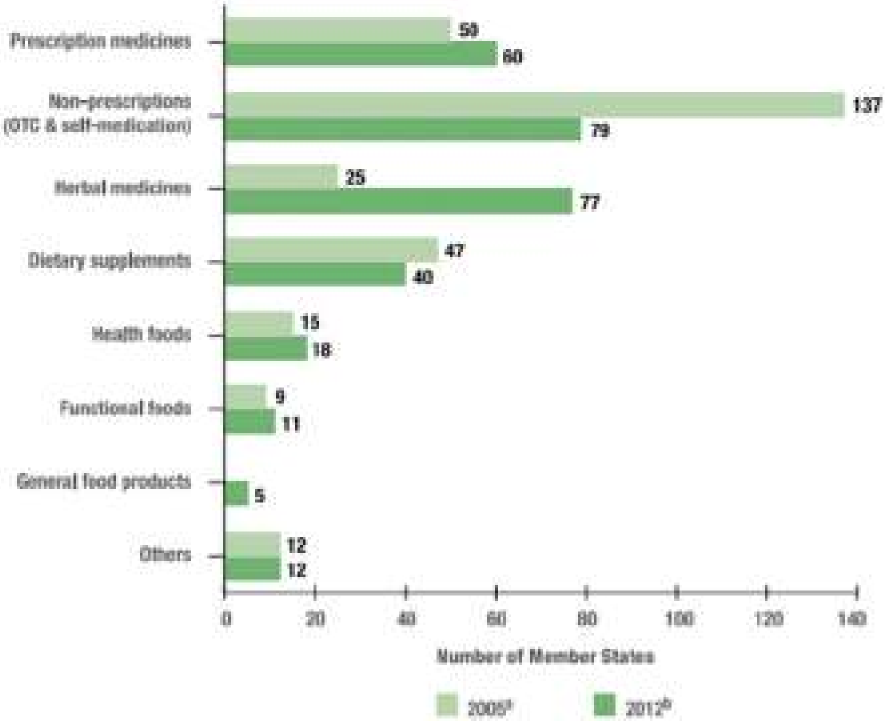

Fig. 2 Types and focus of national herbal medicine laws or regulations. (Source: adapted from WHO [94])

The importance of these herbal medicine governance frameworks in healthcare delivery is to align national structures with public healthcare foci of numerous international bodies and conventions. For instance, herbal medicine has gained recognition from the World Health Organization (WHO) in the Beijing Declaration as an important provider of primary healthcare [92]. The World Trade Organization (WTO) laid similar emphasis on the role of herbal medicine in strengthening healthcare in regions across the globe [97]. Even though the contribution of herbal medicine has been downplayed in many developed countries, these countries have alluded to the successes of this type of medicine in successfully controlling and managing chronic diseases associated with lifestyle [94]. The increasing usage of herbal medicine has been consolidated by rising healthcare costs and the rising cost of allopathic drugs. Herbal medicine aside from its curative and healing tendencies for medical conditions is also a representation of the skills, knowledge, and belief systems of indigenous people which are harnessed for the diagnosis and treatment of mental and physical ailments and the maintenance of general health conditions [94].

Table 1 Herbal medicine policies, regulations, and regulatory pathways

Country/ region	Policy and legislation	Year	Focus
United States	Dietary Supplement Health and Education Act	1994	Regulation of dietary supplements which are defined as any herb or part of a herb, botanical, and natural concentrates, metabolite, and constituent of extract
Canada	Natural Health Products Regulations (SOR/2003-196)	2003	Registration, licensing, labeling requirements, and recommended utilization approach of natural health products
European Union	Herbal Medicinal Products Committee European Directives 2001/83/EC and 2003/63/EC and amended versions like 2004/24/ EC (European Herbal Legislation)	2001, 2003, 2004	Provide guidelines for the authorization, evaluation, and safe use of herbal medicine products and resources (collection, characterization, manufacturing, testing, and quality control)
Brazil	RDC 48/2004	1967	Regulation of herbal drugs
India	Drug and Cosmetic Act and Rules	1940 and 1945	Regulation of herbal drugs and herbal medicine preparations
Ghana	TMPC Act and GMP rules	1992 and 2000	Registration of traditional medicine practitioner and their products
Nigeria	Decree Number 15/1993	1993	Regulation of finished herbal medicine products
United Kingdom	Medicines Act	1968	Registration, licensing, and regulation of herbal medicines
Korea Republic	Pharmaceutical Affairs Act	2015	Regulation of herbal medicinal preparations
Ethiopia	Proclamation # 176/99 and 1112/ 2019	1999 and 2019	Regulation of the preparation and finished herbal medicine products
China	Law of the People's Republic of China on Traditional Chinese Medicine (TCM law)	1986	Promotion and regulation of traditional Chinese medicine
Kenya	Pharmacy and Poison Act (cap 244)	2019	Control the trade and administration of drugs and poisons
Tanzania	Pharmaceutical and Poison Act	1978	Control the trade and administration of drugs and poisons
Hong Kong	Hong Kong Chinese Materia Medica Standards	2009	Ensure the safe use, trade, and quality of Chinese Materia Medica
Gabon	Ordinance # 001/95	1995	Recognition of herbal medicine
Australia	Therapeutic Goods Act	1989	Regulation of medicinal products containing such ingredients as

(continued)

Table 1 (continued)

Country/ region	Policy and legislation	Year	Focus
			herbs, vitamins, minerals, nutritional supplements, homeopathy, and certain aromatherapy preparations used in complementary medicine
Bolivia	Law # 1737	1996	Regulation of herbal medicine products and materials
Indonesia	Minister of Health Regulation # 007	2012	Provide criteria and permit for the distribution and sale of herbal medicine
Russia	Article 41 TM/CAM	1991	Regulation of herbal medicine prescription, use, sale, and production license
Democratic Republic of Congo	Organization of the Exercise of the Profession of Practitioner of Traditional Medicine	2002	Registration and regulation of herbal medicine formulation, content, and use
Argentina	Resolution 144/98	1998	Management of phytotherapeutic medicines and vegetable drugs
El Salvador	Decree # 55	1988	Regulation of herbal drugs as prescription and over-the-counter medicines
Peru	Decree # 584 and Supreme Decree # 002-92-SA	1990	Registration and regulation of herbal medicines

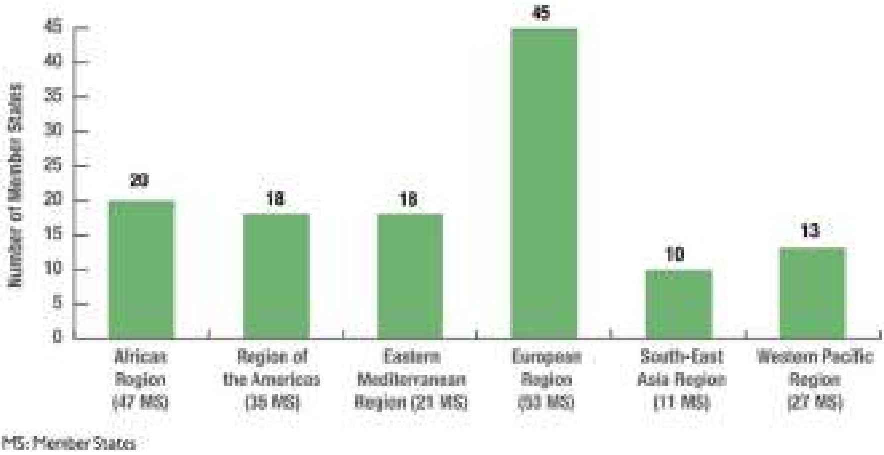

Fig. 4 Distribution of WHO member states with herbal medicine national policies by region. (Source: adapted from WHO [94])

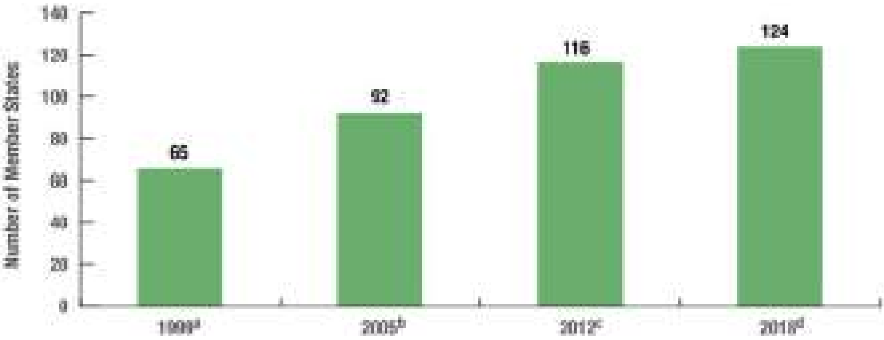

Fig. 5 Increase in the number of WHO member countries with some form of herbal medicine laws and regulations from 1999 to 2018. (Source: adapted from WHO [94])

Transforming existing national herbal medicine policies into a global policy strategy will help govern the education of practitioners and users, protect their right to practice and use herbal medicines, ensure safety and competence, and promote the reputation, quality, and efficacy of herbal medicines. A global policy will help address variations in care outcomes within and across countries in the world through an arsenal of strategies that are simple, cheap, and attentive to local needs (Busse et al. 2019). Existing evidence abounds to support the continued development of the practice, but initiatives need to be supported with appraisal mechanisms including research and policies [42]. For instance, this will regulate the admission of new practitioners and the validation of their practices, content, and accountability, balance the extraction and use of raw materials, and promote their continued education.

5 Medical Regulations and Policies that Are Relevant to Herbal Medicine and Practices

The pharmaceutical sector in recent times has shown a vested interest in studying various plant species because they can both be valuable and advantageous resources for the creation of novel medications and help preserve biodiversity [69, 87]. International agencies and national governments the world over have begun to establish regulatory frameworks for producing and distributing herbal medicines due to the increased interest in researching plants as therapeutic resources [89]. This is critical since many herbal products used may probably not have undergone any form of safety analysis to assess their effectiveness with negative consequences associated with some [70, 89]. According to Vyas et al. [89], there are difficulties in adapting herbal medications, which have been developed over many generations, to a contemporary regulatory system. Yet, China and India, two nations that have formalized training as a part of their national health systems to guarantee that traditional medicine attains high quality in the provision of healthcare, have prospered in this transformation [70].

To understand the usage of medicinal plants, it is essential to keep in mind that there are certain conceptual disparities while discussing herbal medicines. Medicinal plants can be used as a DIY remedy, as in tea, as a source of inspiration for new pharmaceuticals, or as an ingredient in herbal products that are sold commercially [49]. The market for herbal medicinal products has been split into herbal remedies and herbal medicinal products in Mexico, another country with a long history of employing medicinal plants [89]. According to the Mexican framework definition, herbal medicine is made up of components of a medicinal plant that have been combined or produced separately into a pharmaceutical form that is known to be effective for treating symptoms. It should not have any characteristics that could endanger human health, and all plant material must be cleaned following established standards. On the other hand, herbal medicines must adhere to stricter quality standards, which may include using standardized plant material or its derivatives that have been converted into various pharmacological forms [49]. The medicinal plant utilized in the herbal medical product needs to have a monograph in the national pharmacopeia proving it is effective and safe. The scope of regulation for herbal medicine in the event is a matter of a jurisdiction's regulatory frameworks due to differences in culture, history, and usage of herbal products [44]. For instance, the US surveillance agency Food and Drug Administration (FDA) has no regulatory framework for companies who manufacture dietary food supplements [44]; this notwithstanding, products containing medicinal plants with therapeutic capabilities require monitoring due to the possibility of negative side effects [43].

Given this complexity in pursuance of policy regulations presented as a result of the varying approaches that may be adopted by different governments, some underlying themes are required for them to be relevant. The World Health Organization has provided an important resolution by drafting the WHO *Traditional Medicine Strategy 2002–2005*. This breakthrough has three principal goals. First, it is aimed at helping to frame government policy. Second, it is meant to ensure safety, efficacy, and quality and to enhance access. Finally, it is aimed at promoting the right use of traditional medicine/complimentary and alternate medicine (TM/CAM) and herbal medicine [24]. These WHO Traditional Medicine Strategy objectives are crucial in bringing about increasing acceptability and relevance of herbal medicine and practices.

National governments need to specifically introduce regulatory systems on herbal medicine in the context of their local medical practices. These regulations are imperative for quality assurance and registration purposes and also to ensure that consumers used high-quality herbal products. Ensuring quality control for herbal medicine is a sophisticated venture as pointed out in several WHO documents including but not limited to Quality Control Methods for Medicinal Plant Materials and the General Guidelines for the Methodology on Research and Evaluation of Traditional Medicine [96]. Regulations on quality control of herbal medicine are thus important to ensuring compliance by small-scale manufacturers. Another important area in the field of regulation that will contribute to herbal medicine practice is the development of reliable information systems on the most common access to traditional and herbal medicine therapies which should be the result of intensive scientific and clinical studies. This will serve as a guide to TM/CAM and herbal medicine practitioners which will consequently help combat the irresponsive use of traditional medicine [17, 96].

There is also the need for medical regulations on the training and licensing of TM/CAM as well as herbal medicine practitioners to improve safety and build trust in herbal medicine therapies as well as promote the credibility of TM/CAM and herbal medicine practitioners in the eyes of consumers. Such rules may be established by either national or international authorities. Whether through statutory regulation or oversight by regional groups like professional associations in the shape of self-regulation, consumers will need to know where to get what information when it is needed. These regulations, like those suggested by the WHO, will go a long way to reduce or eliminate misinformation and bring sanity into the field of herbal and complementary medical practices and products. There are numerous guidelines for the training of TM/CAM and herbal medicine practitioners developed by WHO and other international agencies and national governments [17].

6 Importance of Sustainable Regulations and Policies for Herbal Medicine and Practitioners

For over millennia, herbal medicine has been relied upon as a form of treatment. However, due to the advent of allopathic medicine and expansion in the synthetic medicine industry, herbal medical practices and products have come under increasing threats that may undoubtedly threaten the continuous usage of herbal products if sustainable policy guidelines and regulations are not instituted. Mainstreaming herbal medicine into primary healthcare is one effective way of creating sustainable pathways to sustained utilization of herbal medicinal products and thus making it imperative to design policy frameworks and regulations to ensure continuous utilization of herbal medicine [49].

Sustainable regulations and policies for herbal medicine, herbal practitioners, as well as users of the product will yield fascinating results and rewards. For instance, the COVID-19 pandemic has reiterated the role of herbal medicine in the development of efficacious drugs and vaccines [49]. Jayk Bernal et al. [36] elicited several merits of herbal medicine including their effectiveness in blockading the multiplication of certain viral genomes, their quick usage to treat new antivirals, as well as producing products with fewer side effects as compared to synthetic medicine. A clinical study by Kumar et al. [40] consolidates this stance as his study revealed highly improved recovery rates from the COVID-19 virus in instances where allopathic medicine was supplemented with herbal medicine.

Herbal medicine also presents an avenue by providing access to explore herbal medicinal products and can contribute to the global commitment to realizing the Sustainable Development Goal 3 of attaining good health and well-being. Integrating herbal medicines into healthcare systems has the potential to increase access to health in both urban and rural settings, which is essential for sustainable development [27]. Herbal medicine also plays a critical role in different socioeconomic and cultural contexts. For instance, due to widening social and economic inequalities amid the devastating threats of climate change, especially on the production side, herbal medicine has become a topical agenda driving a lot of discourses [69]. Malhi et al. (2008) contend that the cultivation of medicinal plants can be exploited as a complementary option in the area of income generation, biodiversity conservation, and stimulating rapid local economic development while also stressing the importance of forest conservation. According to research [6, 48], the Brazilian Amazon plays a significant role in the regional and global water cycle as well as a crucial carbon sink in addition to its sociocultural significance. Chagnon and Bras (2005) explained that land use alternations, especially those linked to widespread land degradation and deforestation, influence precipitation patterns globally, thus stressing the need for herbal medicine sustainability through sustainable policy regulations and practices.

Herbal medicine has also been argued to tend to bioeconomy promotion as it recognizes economic activities and their associated value chains in the context of biodiversity [5, 69]. Complementing the above, in global attempts to attain climate change mitigating targets, keeping global temperatures at bay, and phasing out fossil resources, the bioeconomy has been highlighted as an important tool. Bioeconomy is noted not just as an academic disciplinary sphere or a business opportunity but serves as a conduit for the integration of all the relevant agencies and activities dependent on bioproducts under a single innovative hub [1, 87]. Besides, bioeconomy has direct benefits for the countries that transition to it, especially in the tropics where it could elicit the support of the locals, increase their livelihood pathways by conserving and restoring lost habitats, and bring people closer to nature, which changes their perspective in objectifying nature, with its attendant negative effects (Lima 2022). The bioeconomy idea has been contested up to this point since it puts more strain on natural resources and encourages overexploitation.

7 Conclusion

Existing national policies and regulations have a defining role in what may eventually become a global policy and regulation for herbal medicine practices, products, and practitioners. These existing national policies can provide the necessary regulatory and legal mechanisms necessary for ensuring global good practice, authentication guidelines, and safety and efficacy evaluation of herbal therapies. Also important is the need to maintain and promote herbal medicine practices as well as meet the socioeconomic needs of practitioners and the ecological and cultural security of resources through global policies and regulations. This will ensure that good manufacturing and administration practices are promoted, regulated, and adhered to by herbal medicine practitioners and users. Herbal medicine policies and regulations could also serve as means to harmonize the herbal medicine market and practice across different continents and bring professionals and consumers together. No doubt, almost every herbal-derived remedies require an assessment to ascertain their pharmacological qualities and safety, but this is not achievable with the current level of disinterest. Modern scientific technologies like next-generation sequencing as well as genomic testing and fingerprinting techniques can help address the pharmacogenomic and metabolomic benefits. Herbal medicine should not be evaluated at the same level as contemporary medicine when it is not receiving equivalent amount of budgetary and policy attention. However, on the practice and practical side, it is fair to compare their benefits using evidence-based medicine. Globalization efforts including goals like the United Nations Sustainable Development Goals should aim to integrate herbal medicine practice, practitioners, and resources. Herbal medicine is not only affected by goals and targets that are medico-centric but are also influenced by policies on biodiversity and environmental management. The threat to biodiversity is having a negative impact on the availability of plant resources that are used in herbal medicine by practitioners because most of them are harvested for use from the wild and less so from cultivated lands and poorly managed wild collections coupled with growing disinterest in farming may threaten the industry without relevant policies and regulations. Through policies and regulations, herbal medicine practice can be reinvented and the vital resources protected to meet and sustain the rapidly expanding herbal product market.

Abstract

Plants, especially herbs, are an essential part of the world's biodiversity; they are crucial to maintaining the environment. Natural ecosystems and the variety of plants that they support are crucial to human welfare and way of life because they offer the conditions for life to exist. For food, and other essentials for maintaining life, about 7000 plant species are used. A number of studies into the biological mechanisms and chemical make-up of herbal treatments have been made, and these investigations have proven to be quite helpful in identifying bioactive plants. The use of these therapeutic herbs is quickly spreading over the world due to the rising demand for herbal medications, herbal treatments, and their secondary metabolites. Unfortunately, the majority of herbal remedies found in natural settings are now increasingly at risk due to their unsustainable use and overexploitation. As a result, many highly valued species are fast becoming extinct. This situation is largely caused by a rise in human population, development, habitat alteration, and the increasing dependence of the vast majority of people on the planet's limited natural assets. This calls on management at all levels to pay attention to the usage and threat to these valuable resources to increase their sustainability.

1 Introduction

Plants are critical to sustaining the ecosystem since they are a vital component of the world's biodiversity. Because they provide the circumstances for life to exist, natural ecosystems and the variety of plants they sustain are essential to human well-being and way of life. Plant species are a valuable source of medications in addition to providing food, particularly when applied in conventional medicine to treat a variety of diseases [1]. Herbal remedies are a large natural resource and are essential for the provision of primary healthcare services, particularly in underdeveloped countries [2]. Since ancient times, herbal remedies and common herbal remedies have been used throughout the world to treat and alleviate a diverse array of human and animal diseases. Herbal remedies are also the most profitable sources of new medications in the world [3, 4]. About 118 of the top 150 prescription medications in the USA are produced using natural ingredients, as are 90% of the more than 1300 herbal remedies used in Europe [4]. In addition, 80% or more of residents in the developing world commonly used herbal remedies for their basic treatment, compared to around 25% of the recommended prescriptions in wealthy countries that are manufactured via the use of natural plant species [4]. The usage of medicinal herbs is growing quickly around the world due to the increased demand for natural health products, including secondary metabolites of medicinal plants [3, 5]. According to a very conservative estimate, the world loses at least one significant therapeutic candidate every 2 years, and the rate of plant extinction is currently between 100 and 1000 times quicker than expected by natural elimination [6]. According to the World Wildlife Fund and the International Union for Conservation of Nature, approximately close to 80,000 different types of flowering plant species are said to be utilised as medication globally [50]. Because of desecration of habitat and overuse, 15,000 of these species are at risk of going extinct [7], and 20% of their natural resources have already been depleted by an increasing number of animals and plants [8]. Although this problem has been known for decades, the extinction threat to herbal remedies has grown particularly in China [3, 9], India [9], Kenya [10], Nepal [10], Tanzania [11], and Uganda [11]. There is much research on the preservation and sustainable use of medicinal plants [1]. Numerous groups of suggestions have been made in order to safeguard them, such as the necessity for integrated conservation measures focused on both in situ and ex situ techniques, as well as the creation of protocols for species inventorying and assessment of status [12]. A viable conservation strategy for medicinal plants with declining populations is the wise use of natural resources. Due to the enormous demands of vast populations, the scenario is particularly terrible in China and South Africa.

2 Relevance of Herbal Remedies in Africa

The World Health Organization (WHO) has projected that 80% of Africans employ conventional herbal treatments. Plant extracts are used in traditional medicine in approximately 85% of cases [13]. This might indicate a strong reliance on natural medicines. Consider that there are around 500 traditional healers for every 40,000 individuals in Sub-Saharan Africa as opposed to only one doctor to grasp the extent of this dependency. Hence, the importance of herbal treatments in African culture cannot be overstated. A variety of issues, such as the growing cost and lack of orthodox treatments for individuals with average salaries, are contributing to the rise of interest in herbal therapies in Africa [14]. The fact that many diseases are becoming resistant to conventional treatments is another factor. For example, malaria parasites are becoming more and more resistant to chloroquine, one of the cheapest and most widely used medications in Nigeria to combat malaria [15]. Another well-known instance is the bacterial resistance to drugs. Another explanation could be that some diseases and infections, like HIV/AIDS, cannot be cured by Western orthodox treatment. As a result of the growth of the human immunodeficiency virus, extensive research has been done on plant derivatives that may be beneficial, especially for use in developing and developing nations.

The fact that employing herbal treatments has little to no drawbacks is another argument in favour of herbalism.

2.1 Raw Materials for Herbs Making/Remedies for Man

Herbal remedies have been used by cultures throughout history to treat a variety of diseases. A 5000-year-old clay slab from Sumer contains the oldest documented evidence of the use of herbal treatments [16]. Traditional medicinal plants continue to be the primary source of healing in many rural and developing countries today [17] (Fig. 1). The therapeutic plant components are prepared in a variety of ways (decoction, concoction, water homogenization, chewing, crushing, steam bath, smoke inhalation, etc.) and are administered through a variety of channels (oral, dermal, nasal, and other body parts) (Table 1). However, the most typical method of herbal preparation for human and cattle health problems is simply crushing and crushing a specific plant component or parts of a plant and homogenising them in water. When used by humans, the medicine is often first decanted. It was discovered that several of the medical plant species studied served many functions for the local population, including charcoal, firewood, building materials, feed, medicine, food, and household utensils.

2.2 Herbal Remedies for Domestic Animals

Many studies of the biological characteristics and chemical composition of ethnobotanical flora have been conducted, and ethnobotanical studies are very useful in the discovery of bioactive plants [18]. Interest in medicinal plants for veterinary health has grown as a result of the various side effects and the rising cost of pharmaceutical drugs [19]. Furthermore, since they represent a minimal risk of antibiotic resistance due to their complex chemical make-up and various biological activities, plants might replace antibiotics in the treatment of multifactorial diseases [20] (Fig. 1).

Erythrina senegalensis has a significant diuretic effect, in contrast to the purgative and convulsant properties of Cassia occidentalis leaves. *Andasonia digitala* is administered to cattle as an antidiarrhoeal [21]. According to reports, the plants *Guleria senegalensis*, *Anogassus leocarpus,* and *Selerocarya birrea* are effective in facilitating domestic animal pregnancies easier [22]. Madubunyi [23] asserts that the root extract of *Nauclea latifolia* has antihepatotoxic effects and prevents the growth of the *Trypanosoma brucei* infection. When used to treat anaemia in rabbits, a mixture of Sorghum bicolor and *Telfaria occidentalis* is more effective hematogenic than commercial hematogenic [24]. Studies have shown that papaya extracts are efficient against *Salmonella aureus* and *Escherichia coli* [25]. When a variety of northern Nigerian plant extracts were evaluated using the microtiter plate inhibition test against poliovirus, astrovirus, and parvovirus, an effective antiviral impact was discovered at values between 100 g/100 l and 400 mg/100 l [26]. It has been shown

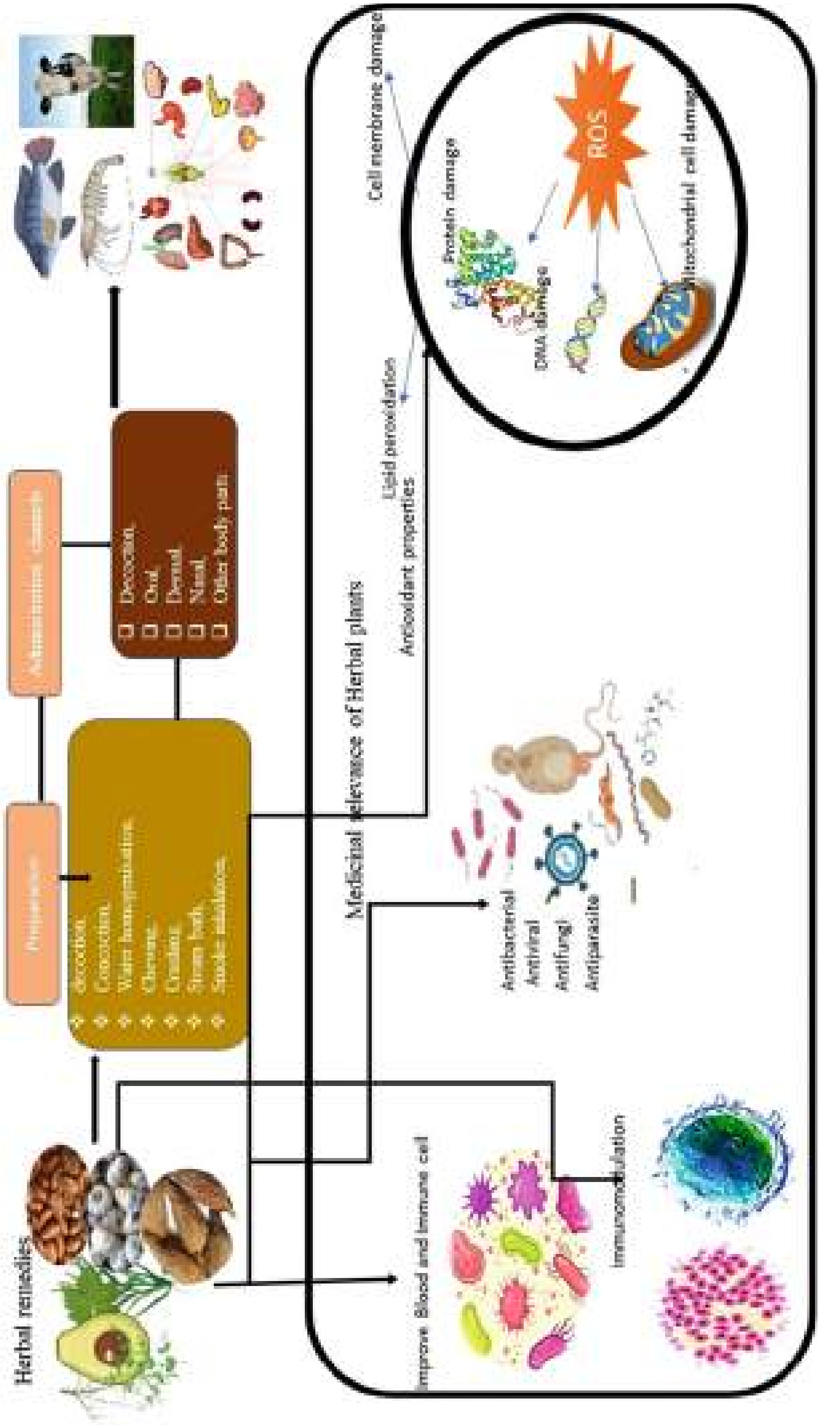

Fig. 1 Medicinal plants and their importance to man and animals

Table 1 Some herbal remedies of relevance to human health

Plant name	Image	Medicinal uses
Marigold		One type of perennial plant in the sunflower family is the marigold. It often has colours such as yellow, orange, red, and maroon and is a member of the Plantae kingdom. Marigold has several health advantages, including: Immune system booster Cures skin conditions Helps with period pain Cure oral sores Relieve joint discomfort Treats fungus-related illnesses Reduce conjunctivitis and eye infection Wards off insects and mosquitoes
Giant milkweed: *Calotropis gigantea*		Crown flowers are a great option for floral arrangements, as they include a group of waxy white or lavender blooms. As long as you plant crown flowers next to a location with direct sunlight, growing them in your yard should not be difficult. When it comes to Ayurvedic therapies for different diseases, it has a prominent position in treating toothaches and healing intestinal issues. May be useful for snakebites and treats a cough/ inhalation
Lemmon grass *Andropogon* spp.		A perennial grass belonging to the grass family, lemongrass is used both as a culinary and medicinal plant worldwide. The medicinal qualities and lemon-like smell are why people grow it. It may grow up to 10 ft tall with a crimson stem at the base. Many deodorants, soaps, teas, and cosmetics frequently use the grass genus as a component Excellent for aromatherapy, detoxifying the body, aiding in sleep difficulties, cure fever, preventing rheumatism, cleaning the skin, and protecting bodily cells
Aloe vera *Aloe barbadensis*		Evergreen succulent *Aloe vera* has very little or no stem. This plant, which has its origins in the Arabian Peninsula, thrives in tropical regions throughout the world. The plant is well-known among contemporary gardeners since it thrives both indoors and outdoors. The plant is used in making goods, including drinks, lotions, and ointments, to mention a few An effective antioxidant, frequently relieves constipation, lessens sunburn, prevents wrinkles, and lessens oral plaque

(continued)

Table 1 (continued)

Plant name	Image	Medicinal uses
Neem *Azadirachta indica*		A tall evergreen shrub known as neem or Indian lilac is grown for its lumber, resin, and fragrant seed oil. Although it is an evergreen plant, excessive dry circumstances can cause it to lose all of its leaves. In addition to being used medicinally, it may also be used as a pesticide to get rid of bugs indoors. It is used to prevent wounds, ulcers, pimples, and acne. May be used to cure a cough. It has antifungal and antibacterial characteristics, stimulates the kidney and liver, decreases oedema and inflammation, and reduces the risk of malaria
Soursop *Annona muricata*		A tiny evergreen tree from which medication is made in the pharmaceutical industry. It has recently received a lot of attention as a meal that fights cancer. It has a high concentration of antioxidant qualities, which is why many people like it. Antioxidant-rich prevents ulcers, treats herpes, boosts energy levels, and keeps joints and nerves in good condition
Moringa *Drumstick tree*		Drought-tolerant Moringa plants are widely grown for their medicinal stems, flowers, leaves, and pods. Although the whole plant is nutritious, the leaves provide the greatest nutrients. A healthy vegetable called moringa can help with issues like battling free radicals, maintaining the endocrine system, reducing inflammation, rejuvenating skin, safeguarding your cardiovascular system, and promoting wound healing
Turmeric *Curcuma longa*		Turmeric is a spice of the ginger family that contains bioactive ingredients. The plant is antibacterial and has many other health advantages due to these components. It is often brilliant orange and has a distinct earthy flavour and scent. It possesses potent antioxidant qualities. Capable of reducing the risk of cancer, lowering the risk of heart disease, improving heart health, balancing hormone levels, strengthening the immune system, and preventing hair loss
Peppermint *Mentha piperita*		The well-known member of the mint family is peppermint, obtained from the cross of watermint and spearmint. Today, peppermint is a popular flavouring for toothpaste, ice cream, soft drinks, and many more products. These are some of its therapeutic qualities. Improves the immune system, fights bad breath, eases gastrointestinal ailments, lowers stress, and eases muscular discomfort

Table 1 (continued)

Plant name	Image	Medicinal uses
Garlic *Allium sativum*		*Allium sativum*, popularly known as garlic, is a plant that belongs to the Allium family and is widely used in cuisine around the world. It has a distinctive flavour that makes it a necessary component in many meals. Provides several additional health benefits in addition to easing those with blood and heart disease. It reduces disease, prevents Alzheimer's, lengthens life, improves athletic performance, stops hair loss, and removes pollutants from the skin
Pawpaw *Carica papaya*		Papaya aids in reducing inflammation and accelerating burn recovery. In addition, it includes lycopene, which enhances blood cell health and reduces the risk of blood clots. Papaya leaf juice is crucial in preventing stroke because it improves clotting, heals the liver, and destroys germs that obstruct digestion. It also helps to stimulate white blood cells and platelets
Mint plant *Mentha longifolia*		The 2–4-inch-long purple flower spikes on this plant are typical. When planted properly in the ground, the mint herb is a drought-tolerant plant. The leaves of this healing plant make a stimulating beverage and can provide a special flavour to the food. Very useful for diarrhoea treatment, removing fever and congestion, relieving nausea, and perhaps curing hepatitis
Thyme: Thymus vulgaris		One of the most used herbs of the mint family is thyme. In addition to several nutritional applications, it has been used to treat a variety of ailments. This decorative plant also has antibacterial and insecticidal qualities. The herb is available commercially in the form of tea and essential oils. Effective for stomach discomfort, diarrhoea, and sore throat. It may be used to treat arthritis, reduce blood pressure, treat coughs, and strengthen immunity
Milkweed *Asclepias syriaca*		A garden plant called a bloodflower provides nourishment for butterflies. It produces bright red blooms almost all year long. Among its health advantages are the following: prevents ringworm, acts to reduce discomfort, heals skin lesions, stimulates the nerve in the brain, combats jaundice, and increases blood-flow precision

(continued)

Table 1 (continued)

Plant name	Image	Medicinal uses
Bamboo *Bambusa vulgaris*		Historically, arteriosclerosis, cardiovascular disease, hypertension, and some types of cancer have all been treated using bamboo leaves
Cannabis sativa		*C. sativa* has also been used to treat rheumatism, epilepsy, asthma, skin burns, discomfort, and sexually transmitted diseases in addition to alleviating gastrointestinal symptoms
Pineapple *Ananas comosus*		The digestive enzyme found in pineapples, bromelain, has anti-inflammatory and analgesic qualities. This is beneficial if you have an injury, such as a burn or sprain, or an infection, such as sinusitis. Moreover, it lessens osteoarthritis-related joint discomfort. The vitamin C in pineapple juice helps keep inflammatory levels low
Albizia lebbeck		Several countries in Africa, Asia, and Australia have used *A. lebbeck* to prevent scabies, lung conditions, piles, bronchitis, stomach tumours, cough, eye issues, and other conditions
Mucuna pruriens		*Mucuna pruriens* (Fabaceae) is a well-known herbal remedy that is used to treat neurological problems, and male infertility, and as an aphrodisiac

that Ageratum conyzoides' crude extract has antibacterial activities [27]. Using the zone inhibition approach, the capability of the methanol leaf extract of *Balanites aegypti* to inhibit Shigella and Staphylococcus albus has been investigated. Staphylococcus aureus was used to confirm the antibacterial abilities of Aegypti [28].

According to Refs. [29] and [30], localized psoroptic mange infection in rabbits can be successfully treated by washing the skin lesions with fibrous palm kernel fruit waste mixed with lime, common salt, lime juice (*Citrus auraatium*), and palm oil for a few weeks [31]. Report that the mahogany seed oil (*Kyaya ivoriensis*) is useful in treating dermatitis brought on by mange and dermatophilosis. Powdered seeds from *Annona squamosa* and *Tephrosia vogelli* are efficient at preventing lice in ruminants and poultry, according to Ref. [29]. During the second day of treatment, tobacco leaf and stem extract is 100% effective against lice and continued to be so for around 56 days after the challenge in West African dwarf goats [32].

2.3 Relevance of Herbal Remedies in Aquaculture

Expanding aquaculture is typically linked to strengthening the culture, which results in congestion and poor water quality, which promotes breakouts of disease and demise [33].

To prevent and cure disease outbreaks and financial losses associated with sanitary deficiencies, veterinarian drugs are used routinely utilised in aquaculture [34]. Abuse of manufactured medications has many detrimental repercussions on both human health and the environment. The muscles of commercially produced animals develop antibiotic accumulation as a result of frequent use [35].

In addition, the use of antiparasitic drugs in bath treatments, such as trichlorfon or praziquantel, can cause resilience to arise and is bad for the environment and animals [36]. Most vaccinations are only effective against one type of disease since it is incredibly difficult to generate vaccines against several types of infections [37]. Although vaccinations are believed to be the most effective strategy to stop disease outbreaks in aquaculture, their high cost discourages fish producers from routinely using them. Alternative disease management tactics in aquaculture are becoming more and more necessary given the serious drawbacks of synthetic medications. Furthermore, because most infections are opportunistic and feed on weak or stressed animals, outbreaks of disease in aquaculture are typically related to the fitness and health of the animals. To protect fish from pathogen infections, alternative therapies should increase fish fitness and immunity [38]. As herbal remedies have been shown to offer a variety of bioactivities, including antistress, immunostimulant, and antiparasitic qualities (bacterial, fungal, viral, and ectoparasites), aquaculture may benefit from employing them as an alternative to chemotherapy [39]. Notwithstanding the recent surge in interest in the use of medicinal plants and plant extracts in aquaculture, rural fish producers have always used therapeutic herbs. The use of therapeutic herbs in aquaculture is supported by several scientific studies [40]. Plants' various active principles, including alkaloids, terpenoids, tannins, saponins, and flavonoids, have been shown to have a variety of benefits, including antistress, hunger stimulation, growth promotion, immune stimulation, and antipathogen capabilities in fish and shrimp aquaculture [41, 42]. When given to farmed fish, several plant extracts are said to increase intake and weight gain [43].

Fish treated with herbal remedies have improved immunological responses, according to [44]. A 42% increase in survival was seen in Nile tilapia (*Oreochromis niloticus*) that had been exposed to the bacterial pathogen *Aeromonas hydrophila* due to enhanced lysozyme, respiratory burst, alternative complement, and phagocytic activity [45].

The biological activities of herbal remedies with antibacterial properties are by far the most studied, according to numerous in vitro studies showing that certain plants have antibacterial action against both gram-positive and gram-negative marine bacteria [46, 47].

3 Operative Threats to Medicinal Flora

Several species of medicinal plants are threatened by both natural and human-induced reasons. However, threat levels differ from one location and one species to another.

3.1 Excessive Use for Local Purposes

A significant risk to herbal remedies, this species is human overexploitation for local use, which also jeopardises the habitats of some economically significant wild species of medicinal plants. In the wild, each of these plant species is subjected to both legal and illicit exploitation because of their therapeutic potential and are all sold locally, nationally, or internationally [48]. The greatest threat to these plant species is the abuse of some plants by locals for medical uses (such as *A. heterophyllum*, *S. costus*, and *P. kurroa*) and export to areas beyond the region [48]. A major threat to the biodiversity of rare herbal remedies is overexploitation for local use. Aconitum heterophyllum, a species with a high-risk index, needs immediate protection [49]. With these plant species, locals take a risk by collecting the entire plant or particular sections of it. The fundamental factor that causes the disappearance of economically viable herbal treatments is excessive and unchecked exploitation [50]. Dar and Naqshi [51] claim that decades of uncontrolled collecting of medical plants have caused numerous species to become extremely rare or even extinct in a region. Locals take a chance with these plant species by taking the entire plant or various sections of it. Excessive and unchecked exploitation is the main factor behind the demise of commercially lucrative medicinal plants in the Kashmir Himalayas [50]. Dar and Naqshi [51] claim that decades of unfettered collecting of medicinal plants have caused numerous species to become extremely rare, if not extinct. Due to overexploitation, the therapeutic plants in Kashmir Himalayas disappear with startling speed [48]. One of the main hazards to medicinal herbs is thought to be overuse [52]. The overuse of the estimated 15,000 different varieties of medicinal herbs puts them at risk [53].

3.2 Landslides/Eroding Soil

Landslides disrupt not only ecosystems but also a substantial section of the natural population [51]. Lapcha [54] asserts that landslides significantly contribute to the vulnerability of the wide variety of medicinal plants. Landslides frequently pose a threat to several species that are only found on mountain slopes. Two examples of plant species that perform well in muddy and damp environments that are prone to landslides and pose a serious threat to their survival are *Anemone rupicola* and *Corydalis cashmeriana* [50]. Due to the landslides' changes to the soil's physico-chemical composition, other ruderal species may proliferate more quickly, which might result in the extinction of endemic species whose natural settings were formerly favourable [50].

3.3 The Excessive Grazing

Most medicinal plant species live in places that are heavily grazed; grazing animals not only consume their leaves, but also destroy the reproductive portions of the species (inflorescence, flowers, and fruits), greatly limiting the size of their populations [48, 50]. When cattle graze the flowers extensively, the majority of individuals in diverse groups are unable to produce seeds (e.g. cows, sheep, and goats) (e.g. cow, sheep, and goats). Grazing and trampling, according to studies, are the factor that is decreasing the number of sought-after herbal remedies [55, 56]. Due to the removal and damage caused by overgrazing, plant populations are at risk of extinction [57, 58]. Overgrazing alters the biological niches in addition to directly devouring them, preventing the spread of new species [59]. Overgrazing hurts the environment, causing the formation of bogs, erosion of the soil, and loss of plant variety. Overgrazing has indirect consequences on the soil biota, damage to plant seedlings, and soil compaction, among others, as well as making the surface more vulnerable to erosion. These actions increase the susceptibility to erosion [48]. The vast majority of plants today appear rare in the vast majority of grazing locations because the grazed component of the species is frequently prone to fungal infection [60].

3.4 Forest Loss and Construction Process

The number of medicinal plant varieties that may still be found in the wild has decreased significantly dropped over the past 20 years as a result of the high rate of forest destruction. The natural habitats of these plants have been harmed by deforestation, which has decreased the variety of medicinal plant species in their original ecosystems. Deforestation poses a serious threat to Southeast Asia's biodiversity, according to Ref. [61]. Many detrimental consequences of deforestation on habitat exist, such as habitat degradation, fragmentation, shrinkage of patch and core areas, and isolation of suitable habitats [62]. Moreover, fragmentation makes it possible to allow weedy plants that require light to colonise new areas encroach on their native habitat on the borders of forests [63]. The array of herbal treatments has been impacted by the random development of highways and other structures in wild environments (forests, meadows, etc.). Some species of medicinal plant native environments have been severely affected by development activity [50]. Construction work was cited by [64] as the primary cause of the lack of diversity of the species. One of the main causes of species extinction that is often emphasised is habitat degradation and fragmentation caused by construction [65].

3.5 Illegal Commerce and Flash Floods

Various medicinal plants have been lost because of the hazard that flash floods offer to different sorts of plants around the world. The terrestrial flora's submergence considerably reduces the need for new individuals and reproduction; certain populations have even been seen to be uprooted. Among the greatest dangers to these species is the recent reports of the illegal trafficking of several therapeutic herbs. These species are at risk of going extinct as a result of the excessive collection of them for smuggling outside of their native habitats [51].

3.6 Invasion of Alien Species and Forage Overharvesting

Significant populations of medicinal plants have been greatly reduced as a result of alien plant species' extensive encroachment [66]. According to the observation of Pandey et al [49], the growth of native populations of *Sinopodophyllum hexandrum* has been severely impeded by the rapid proliferation in between forest gaps. The suppression or eradication of native species by invading species has a negative influence on biodiversity and the ecological system's ability to operate normally. They can gently influence the structure and species composition of the ecosystem by changing how nutrients are cycled through it [67]. Three important herbal remedies, *A. heterophyllum*, *Sinopodophyllum hexandrum*, and *A. absinthium*, are harvested along with other types of grass that the community consumes. The bulk of these plants are chopped down during the peak flowering season (July to August), as their seeds are not available for regrowth in the subsequent growing season. The *Acorus calamus* is chopped, which puts its existence in peril because it is a desirable plant species.

3.7 Uncontrolled Tourism

Due to a growth in tourism-related activities, the allowable number of tourist attractions within various ecological zones has been surpassed, jeopardising biodiversity. Certain species of medicinal plants are in danger of going extinct, and excessive visitor traffic in popular tourist destinations also wreaks havoc on their delicate environments. Trampling is one of the negative consequences that damage the medicinal flora in its natural environment [55, 56]. Unrestricted tourism activities are the main contributors to the species' scarcity, claim [57].

3.8 Conversion of Grasslands and Forests for Agricultural Purposes

Change in land use, which is the largest threat to biodiversity globally, is also a concern for medicinal plants [45]. Land use modifications remove the medicinal plant species' natural habitat, hence reducing their range and hastening their extirpation. The alteration of land use constitutes one of the main risks to biodiversity in many nations, which also results in the isolation of suitable ecosystems [62]. One of the main risks to medicinal plants is supposedly changes in land use brought on by increased agricultural output [68].

3.9 Quarrying and Mining Process

The medicinal flora is seriously endangered by unregulated mining. Mining operations currently pose a danger to the natural habitats of major herbal remedies. According to reports, the world's medicinal plants and their ecosystems are in peril due to mining, stone quarrying, and associated activities [69]. Three endangered fern species, as well as *Calotropis gigantea* and *Azadirachta indica* in Ewekoro, Nigeria, have lately been discovered to be threatened in Chhattisgarh, India [1, 54]. Additionally, industrial pollution from cement factories, notably cement dust, has put some plant species in danger. Disturbed habitats generated substantially fewer seeds than other natural areas where the plant thrives. This may be the case because a thick layer of cement dust has been spread across receptive stigmas, thereby preventing pollen from germinating there. It is important to investigate whether heavy exposure to cement dust has an impact on photosynthesis. Together with other risks, pollution was found to pose a serious threat to biodiversity [70]. Cement dust's chemical composition and pH have a significant impact on how plants utilise carbohydrates. Additionally, cement dust promotes leaf cell surface plasmolysis, which hinders starch production [71]. According to Ref. [72], alkaline cement particulate from electric filters purportedly prevented the production of reducing carbohydrates right away.

4 Sustainability in the Source of Raw Materials

In recent years, patients have mostly embraced herbal remedies, but the demand is increasing exponentially, and natural resources cannot keep up. Regrettably, the bulk of the herbal remedies found in undomesticated settings are currently going extinct as a result of their unsustainable use and overexploitation. Some highly valued species are rapidly becoming extinct as a result of causes such as population increase, urbanisation, loss of habitat, and an increased reliance of the vast majority of people on limited natural resources [73]. These human-made actions are thought to have significantly accelerated the pace of species extinction [74, 75]. In all, 96, 951 species have been assessed for danger categories, and 26,840 of them have been designated as threatened [51]; a few risks are habitat destruction or depletion, excessive utilisation of resources, invading species, industrial development, pollution, and rapid climate change [52]. Although it takes 3–5 years for certain wild herbs to organically regenerate, this period is excessive considering the increasing demand. As a result, it is becoming more and more difficult to responsibly use herbal resources. Long-term sustainable use of herbal resources requires striking a balance between social benefits, ecological stability, and raw material market demand [5]. To address issues of diminishing natural resources and the increasing market demand for wild herbal remedies, cultivation and natural nurturing were now the primary production methods [6]. Large-scale cultivation is a quicker and more efficient method than other methods of producing the required quantity of basic medicinal components. Although cultivation requires a large amount of farm space, the main obstacles to restricting its use to all medicinal plants are heavy metals, pesticide residue, plant disease, and pests. Moreover, the raw materials' output quality occasionally falls short of the required clinical requirements. Natural fostering, also known as a wild nursery or semi-imitational culture, is an innovative method of growing herbs. By integrating economic benefit with species conservation, the tension between the need for subsistence and the preservation of biodiversity can be effectively handled. By conserving and rebuilding healthy populations of wild species, China has profited from this technique [6]. It still has limitations, though, such as a drawn-out manufacturing cycle and subpar productivity, which prohibit it from swiftly satisfying the market's escalating demand. Although the production of raw medicinal components can benefit from natural care, wild harvesting, and cultivation, these methods alone cannot fully address the prevailing problems of sustainable exploitation of herbal resources.

4.1 Medicinal Herbs Under Traditional Management

Traditional legal systems for managing resources are typically more successful than enforced ones in stopping overharvesting and other harmful practises [76]. Traditional beliefs and practises include limiting how plant resources are used. The Indigenous knowledge linked with these cultural practises has been employed for many generations to fairly utilise the plant resources despite the fragile ecosystem in which they live. Knowledge passed down from generation to generation among Indigenous peoples is strongly related to the traditional method of land management method.

Herd expansion and crop rotation were the techniques adopted. These techniques provide the elders the ability to rest the grazing areas and feed their cattle a variety of browse and grass types, giving them enough ground cover for grazing throughout both the dry and rainy seasons. Furthermore, it is culturally unacceptable to cut trees, particularly for charcoal. Instead of being felled for animal feed, bushes or trees are lopped, and leaves, seeds, and pods are thrown with sticks. The preservation of biodiversity is aided by these traditional ways of life. Simonsen [77] made the same finding among pastoralists who resided in different locations. This may show how pastoral and agricultural groups might apply their combined management skills in situations where resources usage is similar. Given the grave circumstances, it is expected that urgent research attention would be given to biodiversity conservation priority in general and therapeutic plants in particular. Prioritising medicinal plant species whose primary distribution range includes the region under consideration, which means that they are almost ever known to exist elsewhere, is the most scientifically valid method for concentrating conservation efforts at the local level [78–80]. Regional rarity, followed by local rarity, and habitat vulnerability, would need to be assigned the greatest weights to use this method [81].

4.2 Conservation Approaches for Herbal Remedies

Regional rarity would need to be given the most weight, followed by local rarity and habitat vulnerability, to use this method [81]. More resources are being removed, mostly from wild populations. The worldwide demand for natural resources has expanded by 8–15% annually during the last few decades [7, 8]. There is a point at which a species' capacity to reproduce is irreparably compromised [82]. There are various alternate sets of guidelines for the sustainability of herbal treatments; offering both in situ and ex situ conservation is one example (Fig. 2).

Fig. 2 Conservation methods for herbal remedies

4.3 In Situ Conservation

Most of the therapeutic advantages of herbal treatments are derived from endemic species, which have molecules of secondary metabolism that react to environmental cues in their natural environments, while they might not appear in laboratory settings [83]. We can protect native species, natural communities, and the intricate web of interactions that connects them by maintaining complete communities in place [84]. Additionally, conservation in the wild increases the number of species that can be maintained while also strengthening the link between resource protection and sustainable use [85, 86]. The establishment of protected areas and the adoption of an an ecosystem-focused strategy as opposed to a species-focused one have been the primary goals of in situ conservation initiatives around the world [87].

4.3.1 Natural Reserves and Establishment of Wild Nurseries

One of the primary causes of the decrease in biodiversity is the state of the ecosystem [88]. Natural reserves protect important wild herb resources and were established to maintain and restore biodiversity [89]. There are now more than 12,700 protected areas worldwide, covering a total of 13.2 million km^2 (8.81% of the planet's geographical area) [90]. Analysing the contributions and ecological roles of certain habitats is necessary to conserve herbal remedies through by protection of important wild ecosystems [91].

Every natural wild plant habitat cannot be designated as a protected area due to financial limitations and competing land uses [92]. Species-focused cultivation and domestication of endangered herbal medicines are carried out in such a wild nursery, which is constructed in a protected area, natural habitat, or anywhere that is only a short distance from where the plants generally grow [93]. Wild nurseries can provide a useful strategy for the in situ preservation of medicinal plants that are rare, endangered, and in high demand, despite the fact that overexploitation, habitat degradation, and invasive species represent major dangers to the abundance of many wild species [94].

4.4 Ex Situ Conservation

For misidentified and endangered herbal treatments with retarded growth, limited supply, and a serious vulnerability to illnesses influencing replanting, ex situ conservation is a beneficial adjunct to in situ preservation [95]. Ex situ conservation, which is usually a swift response to preserve medicinal plant resources, tries to nurture and naturalise endangered species to secure their survival and occasionally to generate huge amounts of planting material required in medication synthesis [96]. When maintained in gardens remote from their natural environments, a variety of previously wild medicinal plant species can be chosen for and protected for reproduction in addition to maintaining potent activity.

4.4.1 Botanic Gardens and the Use of Seed Banks

According to Havens et al. [95], botanical gardens can protect ecosystems to aid in the survival of rare and threatened plant species. In addition, they are crucial for ex situ preservation [90]. Although live collections often only include a small number of specimens of each species and are consequently of limited utility for genetic conservation, botanical gardens offer numerous unique characteristics [2]. They often have a flora with a large variety of plant species that are grown locally under comparable conditions and are ecologically and taxonomically diverse [97]. Since seed banks offer a more efficient way than botanic gardens to preserve the genetic variety of many therapeutic plants ex situ, Li and Pritchard [98] advocate using them to preserve the biological and genetic diversity of wild plant species. The most well-known seed bank is the Millennium Seed Bank Programme at the Royal Botanic Gardens in the United Kingdom [99]. Seed banks make it easy to obtain plant samples for analysis of their characteristics and information that is useful for protecting the remaining natural populations [98]. Two difficult problems in seed banking are how to actively encourage the regrowth of wild populations and how to reintegrate plant species into the wild [98].

4.5 Cultivation Practice

Although wild medicinal plants are generally regarded as more potent than those found in domestic cultivation, the practice of domestic cultivation is common and well tolerated [100, 101]. Horticulture presents the opportunity to apply cutting-edge methods to address concerns with the cultivation of medicinal plants, like harmful components, pesticide pollution, low concentrations of active compounds, and incorrect identification of biological origin [102]. Production stability may be ensured, and the yields of active chemicals, which are virtually invariably secondary metabolites, can be improved when cultivating under-regulated growth conditions. The perfect conditions for water, fertilisers, optional additions, and climatic factors like temperature, light, and humidity are provided through growing methods.

4.5.1 Standard Agricultural Practises (SAP)

Standard agricultural practises (SAP) for herbal remedies have been developed in order to control production, guarantee quality, and facilitate the standardisation of herbal medicines [103]. Using an SAP method ensures that herbal medicines are of a high standard, are secure, and do not pollute [104]. A wide variety of subjects are covered by SAP, such as the ecological significance of production sites, germplasm, cultivation, gathering and safety aspects of pesticide assessment, macroscopic or microscopic authentication, chemical identification of bioactive compounds, and inspection of metal elements [105]. Several nations strongly promote the usage of SAP. For instance, in regions with these therapeutic plants, Chinese authorities have pushed for the manufacturing of widely used herbal medications. The use of organic fertilisers, which continuously supply nutrients to the soil and improve soil stability, has a considerable impact on the development of medicinal plants and the synthesis of important chemicals. For instance, *Chrysanthemum balsamita* produced more biomass and had a higher concentration of essential oils than plants that did not get organic fertilizers [106]. If we want medicinal plants to endure and develop over time, organic farming is becoming more and more crucial [107].

5 Sustainable Use

When therapeutic plants that grow slowly and in low abundance are harvested destructively, resources are frequently exhausted, and even species end up becoming extinct [108]. Therefore, it is critical to think about sustainable applications for medicinal plants and develop effective harvesting methods. For medicinal plants (such as herbs, shrubs, and trees), root and whole-plant harvesting does more harm than it does for leaves, flowers, or buds. Herbal remedies derived from whole plants or roots can be safely replaced by using the leaves of the plants as medicine. Wang et al. [109] discovered, for instance, that ginseng root and leaf-stem extracts have equal pharmacological activity, with the leaf-stem extract having the benefit of being a more sustainable resource.

6 Conclusion

The use of herbal remedies and phytonutrients, commonly referred to as nutraceuticals, continues to increase quickly around the world as more people turn to these products for the treatment of various health conditions in diverse national healthcare contexts.

According to estimates, up to four billion people, or 80% of the world's population, rely primarily on herbal remedies for their medical needs. In many societies, traditional medicine that uses herbs is valued as a fundamental component of culture. The adoption of herbal remedies has been a thing of global acceptance, its usage is not only limited to rural communities but also urban centres and across the developed nations. Also, their utilisation do not limit to man only, as highlighted; domestic and aquatic animals are also involved. Several factors that threaten the sustainable use of these herbal remedies must be investigated; both the scientist and other stakeholders must work together, although in different capacities to ensure sustainability in the use of natural gifts called herbal remedies.

Abstract

This chapter documents currently known pathogenic microorganisms that are associated with herbal remedies as well as their health impacts on consumers and discusses the need for standardized regulatory practices as a form of quality assurance of herbal remedies. Phytomedical practices are used since time immemorial but remain crude despite a growing number of users around the world. Importantly, there is a potential public health emergency as some herbal remedies contain microbial contaminants and heavy metals as a legacy of crude production techniques. Therefore, there is a need to put mechanisms in place to ensure that herbal remedies are safe for human use. Herbal remedies typically contain phytochemicals that exhibit antimicrobial activities, but issues linked to the toxicity of the crude extracts, method of extraction and purification, the dosage of administration, and microbial contaminants have negative implications on the practice, the general public, and users. Some microorganisms associated with herbal medicines have been known to cause serious harm, especially to children, the elderly, and immune-compromised people. Some microbes that have been isolated from herbal remedies include *Escherichia, Salmonella, Pseudomonas, Streptococcus, Staphylococcus, Klebsiella, Bacillus, Enterococcus, Proteus, Citrobacter, Moraxella, Serratia, Citrobacter, Enterobacter, Shigella Candida, Aspergillus, Cladosporium, Rhizopus, Mucor,* and *Alterneria*. Also, some harmful materials like heavy metals, dust, pesticidal residues, microbial contamination, and toxins have been isolated from adulterated herbal remedies. There is an urgent need to adopt more strategic quality control practices to reduce the density and diversity of microbes and other contaminants found in formulated and ready-to-use herbal medicines. Some important strategies would be knowledge sharing, formulating policies, and pharmacovigilance, which are capable of ensuring the quality, safety, and effectiveness of traditional and complementary medicine in the national health systems.

1 Introduction

For centuries, plants and their derivatives have been used for food, treatment, and management of disease conditions and control of pests. Plant resources are a major source of food for humanity. Some of the common plants that are used as food have been comprehensively documented in the literature [1–20]. Some of the plants have been documented to possess pesticidal properties particularly effective in the control of mosquitoes [21–26]. Furthermore, certain plants have been reported to be effective in the management of disease conditions particularly the ones caused by infectious agents [27–43].

The use of plants as medicine has been documented before the era of modern medical practices most notably by the Chinese, Indians, Greeks, Southeast Asia, and Africa [44–48]. This unorthodox practice was the only means of treatment for various illnesses and diseases, but now it is most commonly referred to as "*alternate medicine*" or "Complementary and Alternative Medicine." Several advances have been made in modern medicine, but with the high cost of conventional medical care, poor or non-existent health insurance, and rise in human population, people, especially in low and middle-income countries, have fallen back to the use of herbal medicine for the prevention and cure of infectious and non-infectious diseases globally [49–51]. According to a survey carried out by World Health Organization [52], approximately 80% of people mostly in developing countries depend on medicines of plant origin for their basic healthcare needs. Street et al. [53] deduced from their study in South Africa that the use of herbal remedies by a vast majority of the population may be a result of several factors including ease of access to the plants, broad knowledge among Indigenous people, and affordability.

In developed and industrialized countries, people view herbal medicine as more wholesome, organic, safe, and promotes healthy living thereby less likely to have adverse effects as opposed to modern medicines which contain inorganic components and may contain certain constituents which may have been sourced through genetic modification, thus viewed as synthetic, and this has made herbal medicine quite popular in the recent decades [54–64]. With the increase in drug resistance of infectious disease-causing agents to conventional medicine, it has become imperative to consider other options for the treatment of infectious diseases [65]. As discussed by Hossaini et al. [66], Konieczynski et al. [59], and Calixto [67], pharmaceutical companies worldwide have begun the incorporation of plant and plant derivatives into conventional medicine for the treatment of various illnesses because of their high level of antioxidants and other phytochemicals; presently, an estimated 60% of antimicrobial and anticancer medications are derived from plant-derived and available for sale, with lots of others still at the clinical trials awaiting approval for use by the general public. According to WHO, plants are the best source for pharmaceutical and health industries in the coming years [68]. China and India are the biggest and second biggest exporters of herbal medicines, respectively, in the world [69], the main trade centres for herbal medicine include Germany, France, Italy, Spain, the United States, China, and Hong Kong [70].

At the moment in Africa, the use of herbal medicine is on an all-time increase, various plant parts (in their fresh and/or dried state), preparations, and finished products are in the market today with the marketers laying claims to their products being able to cure various ailments. There are no regulatory and standardized mechanisms in place to checkmate the authenticity of these products as regards their quality, safety, efficacy, and dosage [67, 71]. This is a major public health concern as medicinal plants even though they are considered organic can become the carrier of potential contaminants like bacteria, fungi, viruses, heavy metals, and pesticide residues, among others, through various points of handling from harvesting, storage, transportation, and preparation and the presence of microorganisms in such herbal remedies may have serious health implications to consumers [53, 71–76].

As observed by Nwankwo and Olime [71], Street et al. [53], Adeleye et al. [73], and Esimone et al. [74], pharmaceutical products of any kind must be sterile; herbal products in developing countries cannot be considered as sterile as most of them are processed and packaged without ascertaining the microbial status of the plants and this will ultimately decrease the therapeutic properties of the products. Regular monitoring of the processes involved in herbal products production, packaging, storage, and dispensing is of utmost importance. The framework or guideline for the manufacturers of these herbal preparations to adhere to and sanctions for defaulters are inadequate in many regions where the use of the herb for the management of diseases is high. The setting up of the aforementioned may spur them to improve their standards and processes. Microorganisms have been reported in every environment including physical, chemical, and biological. Microbes by their natures can withstand extreme environmental conditions, hence based on temperature they have been classified as psychrophiles, mesophiles, thermophiles, and hyperthermophiles. Human commensals and pathogens are mainly mesophilic. Several microbes have been reported in the air environment [24], drinking water sources [75–77], food sources of humans including ready-to-eat foods [12, 13, 16, 78, 79], palm wine [18], Palm Weevil (*Rhynchophorus phoenicis*), Palm oil [5, 8, 20, 21], herbal medicines, etc.

This chapter documents currently known pathogenic microorganisms associated with herbal remedies and their economic importance, health implications on consumers, and the need for standardized regulatory practices as a form of quality assurance of herbal remedies. It presents an overview of herbal medicine formulation and constituents, classifications of herbal medicines, sources of microbial contaminants found in herbal remedies and their microbial density, health implications of the microbial contaminants found in herbal medicine, and sustainable quality control strategies to prevent or minimize the microbial contaminants in herbal remedies.

2 Overview of Herbal Medicine Formulation and Constituents

Herbal medicine is popular worldwide, especially among people living in developing countries where there is limited research on the products' ability to scientifically prevent or cure the diseases and ailments attributed to them [80]. The World Health Organization describes herbal medicines as plant-derived preparations which contain raw or processed ingredients got from one or more plants and has therapeutic or other health benefits to humans [28, 29]. According to Osuntokun et al. [81] and Jamilu et al. [44], herbal medicine is also often used interchangeably with "phytomedicine" and refers to the use of one or more plant components and in some cases the whole plant including the seeds, flowers, leaves, roots, bark, fruits, rhizome, or stolon for medicinal purposes through extraction, concoctions, infusions, decoctions, and in finished products. Sometimes, herbal medicines contain active substances like animal and mineral materials that are not of plant origin and are still considered natural and organic in some countries. Pakdemirli et al. [70] stated that according to the WHO database, there are an estimated 20,000 medicinal plants commonly used in the world, and China, India, and the United States are the top three producers with 4941, 3000, and 2564, respectively, while others include Vietnam with 1800, Malaysia with 1200, Indonesia with 1000, and Turkey with 500.

A large number of medicinal plants have been identified for the essential oils they have which are useful because of their antimicrobial properties, and some have also been known to reduce cholesterol and lipids in the blood [82]. According to Osuntokun et al. [81], herbal medicine is used for not just curative purposes but also for libido enhancement mainly among sexually active males, improved fertility, immune system booster, body system detoxifier, and cleanser. Currently, there is a high rate of consumption of teas which are being used interchangeably with infusions derived from plant parts and are most commonly called herbal teas as they are not got from the *Carmellis sinensis* plant [83] because they are considered to be free of caffeine [84] and have several properties including antioxidants [84], anti-inflammatory [67, 84], anticancer [66, 85], antihypertensive [84], analgesic [66], and sedative [67].

Generally, herbal medicines have received tremendous attention with 80% of the world's population depending on herbal medicines as their primary healthcare needs [86–88]. Interest in herbal drugs has been a thrust area worldwide as they are safe, broadly effective, and with less or no adverse effects. Among the approved pharmaceutical products used today, 40% of them are derived from natural compounds. Natural compounds come in different herbal formulations containing various parts of the plants, be it a leaf, flower, root, fruit, seed, stem, wood, gum, rhizome, berry, twig, bark, lichen, fungi, algae, or the entire plant [89]. These formulations constitute one or more plant components or processed plant components at certain quantities of their bioactive compounds to provide the essential nutrient values to treat various ailments. Herbal formulations have been widely accepted as therapeutic agents exhibiting varied properties such as anti-inflammatory, antioxidant, anti-cancer, anti-diabetic, antihypertensive, anti-fertility, antibacterial, antifungal, antiviral, hepato-protective, anti-parasitic, anti-mutagenic, antidiarrheal, analgesic, and anti-aging as well as immunomodulatory [90–94]. Thus, the use of herbal medicines with complementary and alternative medicines for the treatment of several metabolic diseases as well as infectious and non-infectious diseases continues to grow worldwide [88]. In major populations of developing countries such as India and China, herbal medicine remains an integral part of their cultural practice and beliefs [95].

Plant compounds constitute phenols, flavonoids, phytosterols, terpenes, alkaloids, tannins, essential oils, vitamins, glycosides, fatty acids, and many other bioactive compounds which together put them as a very rich medicinal formulation. In almost every plant, phenolic compounds are the most abundant secondary metabolite and are chemically very heterogeneous. Derivatives of plant phenolics include phenolic acids, flavonoids, tannins stilbenes, and lignans, where flavonoids are the most abundant polyphenols. Among the flavonoids, catechin is present in tea, naringenin in grapes, daidzein, genistein, and glycitein, the main isoflavones in soybean, quercetin present in apples, and broccoli, and anthocyanin in almost all berry fruits. The functional hydroxyl group present in phenolic compounds acts as a hydrogen donor and, thus, can scavenge free radicals making them an excellent antioxidant [96] with a vast spectrum of biological activities. Herbal formulations containing fruits and vegetables in the form of juices or beverages can also accumulate high concentrations of phenolic acids, flavonoids, carotenoids, anthocyanins, coumarins, alkaloids, polyacetylenes, saponins, terpenoids, and tocopherols, and thus they become highly antioxidant, anti-inflammatory, anti-carcinogenic, and anti-aging [97].

Herbal formulations undergo different pre-extraction and extraction procedures to preserve the properties of the active biomolecules. Often the dried samples are preferred over the fresh samples as it helps in the removal of moisture and does not deteriorate faster than the fresh ones. Drying also prevents bacterial activity and restricts fungal growth; however, essential oils are often found in fresh samples. Plant samples can be air-dried, freeze-dried, or can be dried in a microwave or oven. Air drying is a lengthy process that can take 3–7 days to months or even a year depending on the type of plant. Drying in the microwave takes the shortest time; however, it may cause the degradation of essential phytochemicals [98]. Freeze drying is based on the principle of sublimation, a complex and expensive method of drying [98]. Once dried, the samples can be in powdered form by grinding to reduce the particle size. Powdered forms give more homogenized and uniform substances and will increase the rate of interaction between samples and solvents through the increased surface area. Smaller particle size <0.5 mm is considered ideal for efficient extraction [98]. For plants chosen based on their traditional practice, the same procedure of pre-extraction as mentioned by the traditional healers to get similar efficacy should be followed [99].

Extraction is one of the critical processes in separating and identifying the chemical components. Based on the polarity of solutes, the solvents chosen for extraction and fractions are obtained in a sequential process. The most commonly used solvents are water, ethanol, and methanol; however, chloroform, ether, acetone, and dichloromethanol are also used. The bioactive components are extracted depending on the solvent being used, for example, methanol and water can often elute tannins, terpenoids, anthocyanin, and saponins. Ethanol can extract tannins, terpenoids, polyphenols, flavonoids, and alkaloids. The choice of solvent mostly depends on what type of bioactive compound is desired, and then, bioactivity-guided fraction can lead to a large array of possible outcomes. To extract hydrophilic compounds, polar solvents such as methanol, ethanol, or ethyl acetate and for lipophilic compounds mixture of dichloromethane and methanol (1:1) or only dichloromethane are considered [100]. There are several conventional methods such as homogenization, maceration, infusion, digestion, decoction, percolation, and Soxhlet extraction [101–105]. Homogenization, maceration, infusion, digestion, and decoction are mostly based on the principle of soaking/dissolving the ground/powdered plant compound into the solvent and either agitating/shaking/heating or kept still for a certain duration and then filtering, whereas specific apparatus is being used in the case of percolation, hydro-distillation technique, and Soxhlet extraction, where the dried/ground/powdered plant material is added along with the solvent. Common solvents used in Soxhlet extraction are methanol, ethanol, or a mixture of alcohol and water [106, 107]. However, there are certain disadvantages of these conventional techniques as they usually require large amounts of organic solvents, and often high temperatures may lead to the decomposition of the active compound.

The non-conventional/modern techniques such as microwave-assisted extraction, ultrasound-assisted extraction, pulsed-electric field extraction, enzyme-assisted extraction, pressurized liquid extraction, supercritical fluid extraction, and surfactant-mediated techniques have several advantages over the conventional ones [102–106, 108]. These techniques improve extraction efficiency and reduce solvent consumption yields. Apart from these, there are several other chromatographic techniques such as column chromatography, thin layer chromatography (TLC,) and high-performance liquid chromatography (HPLC) which yields pure bioactive compound with the minimum solvent requirement. The final extracted plant compound can be in different formulations and administered in different doses depending on its bioavailability, potency, and toxicity. It can be in the form of the tincture (usually alcohol and water extracts), decoction (filtrate of boiled herbs in water), herbal glycerates (extraction in glycerine), capsules (solid dosage usually contained in gelatin container), tablets (a formulation containing glidants, lubricants, or binders), oxymels (sweet and sour herbal formulation with honey and vinegar), lozenges (sweet-flavoured solid preparation that dissolves slowly in the mouth), ointments/balms/creams (semi-solid preparation usually for external use), herbal suppositories (solid dosage meant for insertion into the rectum), herbal pessaries (meant for insertion into the vagina), herbal poultices/plasters/fomentations/compress (wrapping the mashed herbs or soaking a gauze/cloth in tincture or infusion over the skin), herbal ointments (warming massage medium), essential oils, juices, processed exudates, teas, syrups, soaps, powders, and pastes [109–117]. The finished herbal products need to undergo several tests to exclude microbial contamination, and toxicity, and to maintain the preservative efficiency, stability, and shelf life [111, 118–120]. The sections outlined herein will shed light on some of those parameters related to microbial contamination in herbal products.

3 Classification of Herbal Medicines

Herbal medicine is a broad term used to cover herbs, herbal materials, and finished herbal products [47, 121–123]. Herbal medicine can be classified into herbs, herbal materials, traditional herbal products, and standardized herbal products. However, according to Ghislenia et al. [122] a plant or a part of a plant like a stem or leaves can be considered herbal material and a finished product if it is well packaged and sold.

3.1 Herbs

Herbs refer to plants or plant parts that are used for medicinal purposes for healing [124, 125], supplementation of nutrients and prevention of illnesses and diseases, and as flavour enhancers either savoury or aromatic in food [126–128]. According to Ezekwesili-Ofili and Okaka [121] and Nikam et al. [47], herbs include roots, bark – mango, stems, fruits, seeds, and flowers – *Moringa*, leaves – neem, rhizomes – ginger and turmeric, bulbs – onions and garlic.

3.2 Herbal Materials

These are mainly raw materials from plants like their juices, gums, sap, essential oils, and resins considered to be medicinal which may be used immediately and/or dried, boiled, roasted, or milled into powders and used singly or in combination [129, 130]. According to Nikam et al. [47], these materials are processed by various local procedures and vary according to the country and the ailment they are targeted to treat, which may be steamed, roasted, or mixed with liquids as carriers.

3.3 Traditional Herbal Preparations

Herbal preparations include tablets or pills, capsules, syrup, drops, and waters made from crude herbal extracts in which the active properties have not been chemically separated [47, 131].

3.4 Standardized/Finished Herbal Products

These are products that contain extracts or other substances that have been purified; they can be combinations of more than one plant and could contain oils, and mineral compounds, and are systematically processed [69, 131]. They are termed mixed herbal products if more than one herb or herbal preparation is used. Any product that contains active substances that have been chemically profiled including isolates from other herbal materials and synthetic compounds cannot be termed herbal medicine [47]. According to Chandra et al. [69], and Indrayanto [45], the processes to achieving a standard herbal product must be thorough and its quality assurance guaranteed; products that contain genetically modified plants, chemically modified and purified compounds, and by-products of yeast, bacteria, and other organisms are not considered as herbal medicine. The processes involved from the harvest, storage, extraction, and purification/concentration for herbal products to be accepted in the global market according to Astutik, et al. [132] include three important sets of quality standards viz.: Good Agricultural Practices, International Standard for Sustainable Wild Collection of Medicinal and Aromatic Plants, and Good Manufacturing processes.

There are notable risks associated with the use of herbal remedies, mainly from the quality of the herbal preparations and finished products [123]. Astutik, et al. [132] observed from studies that in some Asian countries, standards for medicinal plants have been firmly established especially in Japan and China using Good Agricultural and Collection Practices, and six countries have Pharmacopeia on medicinal drugs including Indonesia, India, Bangladesh, Sri Lanka, Vietnam, and Thailand while nine countries have well-documented monographs on herbal drugs, namely, India, China, Korea, Indonesia, Malaysia, Vietnam, Myanmar, Thailand, and Sri Lanka. From investigations by Osuntokun et al. [81], in Nigeria traders and herbalists are not keen on revealing the formulae for their remedies; hence, they cannot be thoroughly assessed to ascertain their quality and safety for consumption. In Europe, there is the European Pharmacopeia which is used as the standard for all herbal products.

4 Sources of Microbial Contaminants Found in Herbal Remedies

Many factors can contribute to the poor quality of herbal remedies, from the point of harvest to the preparation of the products. Good manufacturing practices (GMP) are required for the production of herbal remedies to reduce the possible risks and damage that may arise from these products to guarantee not just the quality but also the safety and efficacy of the products. They include identifying the species of medicinal plants correctly, good hygiene, and sanitation methods for the materials used during the process but especially for the starting materials [88]. These contaminants can be further categorized into external and internal factors (Fig. 1).

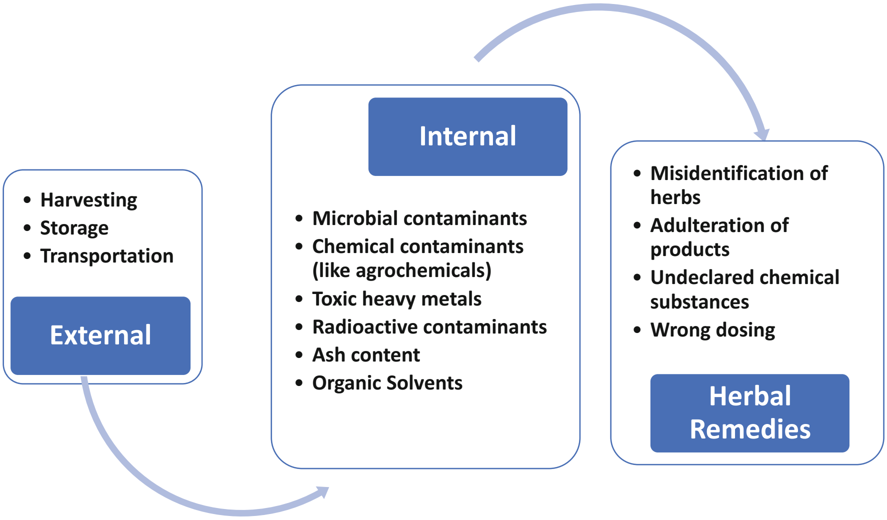

Fig. 1 Contaminants affecting the quality of herbal remedies. (Adapted from [124, 133, 134])

Microorganisms are ubiquitous, and it is nearly impossible to have products that are fully free of them. Regulatory bodies all over the world have set standards by which microorganisms can be tolerated. Microbial contamination of herbal remedies is a cause for concern as they create more illnesses and diseases for consumers rather than healing them. Many medicinal plants harbour naturally occurring microorganisms that are innocuous to the plants but can become pathogenic to humans by reducing the quality of the plant and causing spoilage. The microorganisms can also come from air and soil which carry millions of them [134]. According to Lutoti et al. [131], a broad range of microbial contaminants from bacteria, fungi, and viruses can be linked to medicinal plants and the extent to which these organisms multiply on the plants depend on the environmental dynamics which may impact the quality of the herbal preparation or product they are used to make. It is therefore imperative that quality control measures are put in place to assess products and reduce the risks for consumers. The presence and proliferation of microorganisms are determined by a range of factors from the plants themselves (i.e. their innate properties) and from extraneous sources.

Some plants may have less microbial load than others due to their morphological characteristics; plants with more distance from the soil may likely have fewer microorganisms than one that is close to the soil, and plants with tougher exteriors like hardened barks and exocarps may not be ideal for microbial growth. Some plants also have antimicrobial properties that will inhibit the growth of certain microorganisms on them; examples include fennel, and basil [134]; and several plants have been known for this which has led to the harnessing of these plants for use as therapeutics. Some plants have antioxidant properties which may restrict the growth of some microorganisms. Climatic factors such as humidity, precipitation, and temperature play a major role in the multiplication of microorganisms during the pre-harvesting and post-harvesting periods through poor handling practices and poor storage of both crude and processed plant materials. In tropical climates, mesophilic microorganisms multiply more as the temperature is generally optimum for their growth [71]. Street et al. [53] observed from their study in South Africa that most farmers, collectors, and traders of medicinal plants do not properly dry the plants which is the most used means of preservation; thus, high records of mould and yeast growth were observed.

5 Microbial Classes Found in Herbal Remedies

Microbial contaminants in any pharmaceutical product may reduce the potency of the product and can potentially cause adverse effects on the consumer; thus, it is expected that all medicinal products be assessed for their microbial quality before authorizing for consumption [71]. According to Kunle et al. [124], materials of plant origin have higher microbial contamination levels than those that have been synthesized, it is expected that herbal medicines carry some load of microorganisms mostly bacteria and moulds arising from the soil and plants where harvesting was done or from poor methods of handling, processing, and storage, and also natural microflora from the air predominantly aerobic spore-forming bacteria are predominant. Pharmacopoeias including the European Pharmacopeia, US Pharmacopeia, and British pharmacopeia have established the limit values for several microbial species that can be tolerated in herbal remedies.

5.1 Total Viable Counts

The total viable counts indicate the level of mesophilic aerobic bacteria in a given sample, according to the route of administration and the class of the herbal product. WHO Guidelines (2007) state that for herbal materials like teas and infusions that have been pretreated (e.g. with heat) or other materials like pastes and salves to be administered topically only, the acceptable limit for total aerobic bacteria count must be a maximum of 10^7 CFU/g or ml of the medicine, while for herbal materials that are ingested, the maximum limit is 10^5 per gram, and for herbal medicines that will require the use of boiling water for steeping before use, the limit is 10^7 CFU/g or ml. According to the European Pharmacopeia [135], the acceptable limit of total bacteria is as follows: 10^3 CFU/g or ml for non-aqueous oral preparations, 10^2 CFU/g or ml for aqueous oral preparations, 10^2 CFU/g or ml for remedies used for cutaneous treatments and vaginal treatments, and 10^4 CFU/g or ml and 10^7 CFU/g or ml for oral preparations containing raw material which is not pretreated and herbal products in which boiled water is added before use, respectively. The British Pharmacopeia [136] gave a general limit of 10^5 CFU/g or ml for all herbal medicines.

5.2 *Salmonella* Counts

The *Salmonella* species are pathogenic bacteria that arise from poor methods of processing and handling because they are widespread; the most well-known diseases caused by *Salmonella* species are diarrhoea-like illnesses like salmonellosis, enteritis, and typhoid fever. However, due to the high degree of virulence, the European Pharmacopeia [135] and the British Pharmacopeia [136] recommended that *Salmonella* sp. must be absent in all herbal medicines at any stage intended for ingestion; i.e. all herbal materials, preparations, and finished products must not contain any trace of *Salmonella* in them. Herbal preparations that are used topically or pretreated must also not have any colony of *Salmonella* as they can become opportunistic pathogens to the users.

5.3 *Shigella* Counts

As with *Salmonella*, *Shigella* is also a pathogenic bacterium and should not be found even in trace colonies in any given herbal remedy. According to WHO [137], also responsible for diarrhoea – illness – shigellosis is the second leading cause of childhood morbidity and mortality in Sub-Saharan Africa and South Asia; in recent times, there has been a notable increase in antimicrobial resistance in enteric bacteria particularly *Shigella*; hence, it is not expected to be identified in any form of herbal medicine, neither herbs, herbal materials, and herbal preparations, nor finished herbal products intended for use internally at any stage [52, 136].

5.4 *Staphylococcus* Counts

Staphylococcus species are normal skin flora in humans but are also a common cause of infections [138]. It accounts for minor ailments like boils and impetigo and can also cause serious diseases like septicaemia, staphylococcal gastroenteritis, pneumonia, folliculitis, and staphylococcal scalded-skin syndrome. It has also been reported to account for 49.2% of bacterial isolates in herbal medicines [139, 140]. Through poor manufacturing and handling practices, herbal medicines can become contaminated with *Staphylococcus* spp from humans [141]. According to The European Pharmacopeia [135] and British Pharmacopeia [136], *Staphylococcus* must not be present in herbal medicines for cutaneous, vaginal, and/or oral use i.e. *Staphylococcus aureus* must not exceed 1 CFU/g or ml.

5.5 Total Coliform

According to the WHO guidelines [52], when some Gram-negative bacteria are damaged, they produce endotoxins in their outer cell membranes which are released, and these endotoxins prompt antigenic response which causes resistance to infections of bacterial origin. Coliforms are intestinal bacteria typically associated with human faecal contamination; according to Kporou et al. [142], the presence of coliform indicates poor hygienic conditions during the preparation and storage of herbal medicines. Coliform bacteria include *Escherichia coli, Enterobacter,* and *Klebsiella;* according to Ameri et al. [143], they are found in the human gut and could be pathogenic especially certain strains of *Escherichia coli* which causes food poisoning; and in Iran's national standard, they are allowed to exceed 10^2 CFU/g or ml. WHO Guidelines [52] require a 10^4 CFU/g or ml limit of *Escherichia coli* for raw medicinal plants and herbal materials that require additional processing; for pretreated herbal materials, the limit is 10^2 CFU/g or ml (*E. coli*) and 10^4 CFU/g or ml (other enterobacteria), for herbal materials to be used internally and for herbal medicines that require boiling water to be added 10 CFU/g or ml (*E. coli*) and 10^3 CFU/g or ml (other enterobacteria). The European Pharmacopeia and British Pharmacopeia require a total absence of *E. coli* and other coliforms from all herbal medicines.

5.6 Fungi Counts

Yeasts and moulds are the most commonly found fungal species in herbal medicines, and they proliferate extensively in materials where moisture content and temperature are not properly controlled. The WHO Guidelines [52] expect that for herbal materials and raw medicinal plants intended for processing, mould yields must not exceed 10^5 CFU/g or ml, for pretreated herbal materials and for those that boiling water can be added before use 10^4 CFU/g or ml, 10^3 CFU/g or ml, respectively, for remedies intended for internal use and other related herbal medicines. British Pharmacopeia [136] states that the maximum limit for yeasts and moulds must not exceed 10^4 CFU/g or ml. According to WHO Guidelines [52] and Kunle et al. [124], some fungal species are known to produce mycotoxins which pose acute or chronic public health risks when ingested through food and/or medicines. Herbal remedies due to poor Good Manufacturing Practices (GMP) may contain mycotoxin-producing fungal species; these mycotoxins are usually produced as secondary non-volatile metabolites with low molecular weight on the crude herbal materials. Mycotoxins act in two ways by eliminating competing microbial species and aiding the invasion of the host tissues by parasitic fungal species. Fungal species most commonly associated with mycotoxins include *Penicillium, Aspergillus,* and *Fusarium,* and their toxins include aflatoxins (the most studied and recorded as a group 1 carcinogen in humans), fumonisins, trichothecenes, and ochratoxins. In infected humans, the mycotoxin severity may depend on the degree of exposure to the fungal species, the age and nutritional status of the individual, and the possible combination of other chemical agents the individual is exposed to (de Sousa Lima et al 2020). According to WHO Guidelines [52], aflatoxin levels must be closely monitored for quality control; several countries have different permissible limits, like Argentina; and herbs, herbal materials, and preparations used for teas must not exceed 5 μg/kg and must be absent for finished herbal medicines and those intended for internal use. In Germany, all materials used for the manufacture of herbal products must not exceed 45 μg/kg.

5.7 Other Microbial Species

Other bacterial species associated with herbal remedies include spore-forming bacteria, chiefly *Clostridium*, *Bacillus cereus,* and *Pseudomonas aeruginosa*. *Clostridium* species can be found in the soil, and they synthesize poisonous exotoxins which can either be in the form of enterotoxins which attack enteric cells or in the gastrointestinal tract and neurotoxins which disrupt the functions of neurons in the human body. WHO [52] states that all herbal materials, preparations, and pretreated and finished products must not have a trace of *Clostridium* in them. According to Ameri et al. [143], *Bacillus cereus* also secretes enterotoxins mainly lecithinase C, phospholipase, protease, and haemolysin which are responsible for diarrhoea-related illnesses. Iran's national standard conditions state that all herbal products must not have more than 100 CFU/g or ml of *Bacillus cereus,* while the European Pharmacopeia [135] has a limit of less than 10^3 CFU/g or ml. *Pseudomonas aeruginosa* is an opportunistic bacterium found in the environment and implicated as the causative agent for several diseases; especially in immune-compromised individuals, it is antibiotic resistant, hence making it a challenge to overcome [49]. The European Pharmacopeia states it must be completely absent from all classes of herbal medicines. Faecal streptococci are pathogens associated with intestinal tract infections; according to Kporou et al. [142], herbal medicines that have colonies of faecal streptococci have likely been in contact with animal or human faeces because like *Escherichia coli* other coliforms are indicators of poor personal and process hygiene making them unsuitable for use. From European Pharmacopeia [135], faecal streptococci must be absent from all herbal medicines. *Micrococcus* species are found in soil, fresh and salt water, and also as normal flora on the human skin and other animals; though not considered to be pathogenic, certain strains of the bacteria can become opportunistic pathogens causing pneumonia, bacteremia, and other diseases [144]. *Listeria monocytogenes* is found in water, soil, decaying plant materials, and in the digestive tract of humans and is known to cause meningitis in newborns and immuno-compromised people.

6 Microbial Density Found in Herbal Medicine

From previous studies (Table 1), several bacterial and fungal species have been recorded in herbs, herbal materials, and finished herbal products which are above the recommended standard by WHO and other pharmacopoeias (Table 2). Some of these microorganisms are normal flora from humans which can be attributed to poor harvesting, processing, and storage methods especially fungal species that are dominant in herbal products in which proper drying and storage methods were not employed. Certain species of bacteria like *Enterobacter* and other coliforms are indicators of faecal contamination either from soil contaminated with human excreta or cross-contamination from humans to the herbs or herbal materials through

Table 1 Microbial counts from previous studies

Bacteria diversity	Fungi diversity	Status (liquid or powdered)	Location/ country of study	References
3.0×10^5	1.1×10^5	Liquid	Davo/cote D'ivoire	[142]
1.2×10^2 (crude plant) 2.0×10^4–6.3×10^6 (finished herbal product)	3×10^3 (crude plant) 1.1×10^2–3.3×10^4 (finished herbal product)	Powder Powder	Syria	[145]
5.2×10^7	2.5×10^4	Powder	Dhaka/Bangladesh	[66]

vectors. Some examples of bacterial and fungal counts in herbal remedies from previous studies are presented in Table 2.

7 Health Implications of Microbial Contaminants Found in Herbal Remedies

Medicines are expected to reduce the burden of infectious diseases not to contribute to it; hence, it is alarming when medicinal and therapeutic remedies are found to be contaminated with the microorganisms they are expected to annihilate or reduce. This is a public health concern as the majority of the world's population in

Table 2 Acceptable microbial standards for herbal materials, preparations, and finished products

Classes of herbal products	Total viable counts	*Salmonella* counts	*Shigella* counts	*Staphylococcus* counts	Total coliform	Fungi counts	*Escherichia coli*	References
Herbal medicines to which boiling water is added before use	10^7	Absence	Absence	–	10^4	10^4	10	[52]
Herbal materials that have been pretreated (e.g. boiling water is used like herbal teas and infusions) or that are used in topical forms	10^7	Absence	Absence	–	10^4	10^4	10^2	
Other herbal materials for internal use	10^5	Absence	Absence	–	10^3	10^3	10	
Herbal products, for making of infusions and decoctions using boiling water	10^7	Absence	Absent	Absence	Unspecified	10^5	10^3	[136]
Pretreated herbal products containing extracts and/or herbal drugs	10^4	Absent	Absent	Absent	10^2	10^2	Absent	
Herbal products containing extracts and/or herbal products not pretreated	10^5	Absent	Absent	Absent	10^4	10^4	Absent	

Dried or powdered botanicals	10^5	Absent	Absent	Unspecified	10^3	10^3	Absent	[152]
Powdered botanical extracts	10^4	Absent	Absent	Unspecified	Unspecified	10^3	Absent	
Containing botanical ingredient	10^4	Absent	Absent	Unspecified	Unspecified	10^3	Absent	
Herbal materials need boiling water before use	10^7	Absent	Absent	Absent	Absent	10^5	10^3	[135]
Herbal materials (not pretreated) for oral use	10^4	Absent	Absent	Absent	Absent	10^2	Absent	
Powdered preparations for oral use	10^3	Absent	Absent	Unspecified	Unspecified	10^2	Absent

Herbal drugs got through hot water extraction process	10^7	Absent	Unspecified	Unspecified	10^4	10^4	10^2	[153]
Herbal drugs got through cold extraction process	10^5	Absent	Unspecified	Unspecified	10^3	10^3	10	
Finished products for oral use	10^4	Absent	Unspecified	Unspecified	10^2	10^2	Absent	

developing countries rely on herbal medicines; it is therefore very important for relevant organisations and regulatory bodies to understand the potential harm any given preparation or product that has not been properly ascertained for its quality can have on the end users. Some microorganisms associated with herbal medicines have been known to cause serious harm to children, the elderly, and immune-compromised people who may or may not be battling with other ailments (Table 3).

Diseases arising from microbial contaminants in herbal remedies are numerous, depending on the class of contaminants. For instance, *Escherichia coli* has been reported to cause gastroenteritis, urinary tract infections, and neonatal meningitis, which mainly depends on the strain [161, 162] *Enterococcus faecalis* tends to cause urinary tract infections, biliary tract infections, ulcers, and endocarditis [146]. *Staphylococcus aureus* can cause food poisoning and gastrointestinal illnesses through the production of toxins. Toxins produced by these bacteria are heat-resistant [51, 146, 161, 162]. *Salmonella* species have been implicated in causing typhoid fever and gastroenteritis. *Salmonella* infections may present symptoms including diarrhoea, stomach cramps, vomiting, and fever [51, 161]. *Bacillus* species are characterised by diarrhoea. *Pseudomonas aeruginosa* has been reported to cause urinary tract infections, respiratory tract infections, bacteremia, dermatitis, bone and joint infections, and soft tissue infections [161, 162]. Izah and Ohimain [2] reported that respiratory tract infections, septicemia, and meningitis are occasionally caused by *Enterobacter* species; bacteremia and endocarditis are caused by some *Bacillus* species. Urinary tract infections are caused by some *Proteus* species. Endocarditis, arthritis, meningitis, intracranial abscesses, pneumonia, and septic arthritis are caused by some species of *Micrococcus*. Aspergillosis, onychomycosis, sarcoidosis, sinusitis, otomycosis, endophthalmitis, meningitis, osteomyelitis, endocarditis, myocarditis, pneumoconiosis, ankylosing spondylitis, hepatosplenic, tracheobronchitis, aspergilloma, allergic bronchopulmonary aspergilloma, rhinitis, and farmers' lung are caused by some species of *Aspergillus*; candidiasis and otomycosis are caused by some species of *Candida*. Mucormycosis is caused by *Mucor* species. Mycotic keratitis and otomycosis are caused by some species of *Penicillium*.

8 Quality Control Strategies

The herbal medicinal market is booming worldwide; with each day when a new product is being included in the market, the concern regarding quality and safety also increases. In this run, the quality standards are often compromised. It is to be remembered that every drug has its effective dose at which it shows its best efficacy; beyond or below, it may be deleterious to the subject consuming it. Thus, it becomes imperative to ascertain that the quality, stability, and toxicity level of herbal medicine is maintained at every level.

Compared to synthetic medicines, there are certain critical aspects about maintaining the quality standard of an herbal formulation starting from the origin of the plant to its clinical application. The chemical composition of the finished product may vary depending on the location of the plant, soil fertility, agricultural

Table 3 Diversity of microbes that have been reported in herbal medicine in different parts of the world

Microbes	Locations	References
Escherichia coli, salmonella species, *Pseudomonas aeruginosa,* and *Staphylococcus aureus*	Macapa, Brazil	[140]
Klebsiella, Pseudomonas, *Candida* species, and *Escherichia coli*	Dar es Salaam, Tanzania	[154]
Bacillus, Aspergillus, and Penicillium species	Southern Nigeria	[71]
Bacillus subtilis, Klebsiella pneumonia, Staphylococcus aureus, Pseudomonas aeruginosa, Enterococcus feacalis, Escherichia coli, Proteus and *Shigella* species, *Aspergillus niger, Aspergillus flavus, Aspergillus fumigatus, Cladosporium cladosporius, Rhizopus arrhizus, Mucor,* and *Alterneria* species	Gombe metropolis, Nigeria	[146]
Staphylococcus aureus, Pseudomonas, Proteus, Streptococcus species, *Aspergillus niger, Aspergillus flavus,* and *Candida* species	Abraka, Delta state, Nigeria	[155]
Escherichia coli, Pseudomonas aeruginosa, Citrobacter divergens, Staphylococcus aureus, Shigella sonnei, Moraxella catarrhalis, Serretia marcenscens, Bacillus, Citrobacter, Enterobacter, Staphylococcus, and *Candida* species	Ghanaian market, Accra	[156]
Staphylococcus aureus, Escherichia coli, Pseudomonas aeuroginosa, Shigella, and *Salmonella* species	Trichy, Tamil Nadu, India	[157]
Escherichia coli, Klebsiella, Bacillus and *Staphylococcus species*	Port Harcourt, Nigeria	[158]
Klebsiella species, Bacillus subtilis, Enterobcter species, Staphylococcus aureus, and *Serretia marcescens*	Ilorin-Kwara State Nigeria	[159]
Escherichia coli, Salmonella species, *Staphylococcus aureus,* and *Pseudomonas aeruginosa*	–	[160]

practice, harvesting season, collection time of the plant parts, post-harvest handling, preservation method of the collected parts, extraction procedure, herbal preparation, and many more aspects [163]. For example, the quality of the herbal product may vary if the leaves are not collected during bloom or the rhizomes are uprooted before the completion of the vegetation period, or the fruits and seeds are collected before ripening or attending maturity. Thus, several intricate aspects are important when it comes to maintaining originality and quality standard. For the production of herbal products at the industrial level, three very vital aspects need to be kept in mind: identification, purity, and composition of active compounds as often they are adulterated and are not at par with the standards laid down for authentic drugs. Often there are chances of wrong identification of plant material, and so voucher specimens should be considered reliable reference sources. Due to the complex nature of herbal formulations, the purity of the product is a serious concern. Indeed, one universal procedure of extraction cannot be considered suitable for every herbal compound, rather it is unique to each of them. However, advanced extraction techniques should be considered. To obtain pure compounds, different chromatographic isolation techniques as mentioned earlier in this chapter are used. Often isolated compounds are adulterated with heavy metals, dust, pesticidal residues, microbial contaminations, insect contaminations, and toxins from fungal infection, which reduces the shelf life and purity of the effective ingredients. Thus, decontamination is an essential step, which can be carried out through conventional methods such as steam heating, γ-irradiation, or using ethylene oxide gas. However, these conventional methods often interfere with the quality of the product and lead to the formation of toxic by-products [164]. To avoid these, new technologies such as decontamination with ultraviolet rays, infrared rays, ozonation, radiofrequency heating, and cold plasma are considered [165]. Ash value assessment also needs to be performed to determine the sulphate, acid-insoluble, and water-soluble ash content in the herbal product to maintain quality [166].

Complex herbal formulations need to be validated with modern chromatographic techniques such as high-performance liquid chromatography, gas chromatography-mass spectrophotometry GC-MS, Fourier-transform infrared spectroscopy (FTIR), ultra-performance liquid chromatography (UPLC), and high-speed counter-current chromatography (HSCCC). These techniques help in determining the consistency of the product. Various other modern techniques such as DNA fingerprinting and immunoassays with monoclonal antibodies are also used to evaluate the purity of the herbal compound [167]. An herbal extract is a chemically complex ingredient, and thus it is a difficult task to validate with a single analytical technique. Thus, a new term called "chromatographic fingerprint" has come into the picture, which is a comprehensive qualitative method recognized by WHO, the US Food and Drug Administration (FDA), and other regulatory bodies of different countries [168]. This technique helps in identifying various biologically active functional groups and compares the chemical composition of different compounds using the total chromatograms obtained from several chromatographic techniques (such as HPLC, TLC, GC-MS, and HS-CCC). The entire chromatograms obtained are coupled to a multivariate analysis that not only helps in determining the identity and authenticity of the herbal preparation but also helps in identifying new biomarkers and active molecules [169].

Pharmacovigilance is also a very important aspect to maintain the quality and safety of herbal drugs as often unregistered herbal formulations are marketed freely, thereby misleading people. WHO has released guidelines in the pharmacovigilance system [170, 171] where it has been addressed that the poor quality and improper use of herbal products lead to the majority of adverse events. Mostly in developing countries, it is often easy to market herbal products without any restraint leading to uncontrolled distribution. At the same time, people have the perception that herbal medicines are not toxic and will not show adverse effects. Unfortunately, this is a serious misconception as often herbal formulations are consumed without proper prescription. Poor-quality herbal medicines can cause severe toxicity, showing deleterious effects and even leading to death if the appropriate dose regime is not followed. Research studies have shown that several unauthorized herbal drugs contained high levels of metals such as mercury, lead, and arsenic. Herbal medicine adulterated with aristolochic acid can lead to serious kidney failure and carcinogenic effects. Betamethasone present in herbal cream often can cause life-threatening anaphylactic reactions [172]. Thus, for monitoring safety, herbal products must include proper labelling specifying the content, instructions for usage instructions, storage conditions, patient information, shelf life, stability, and quality control information.

Recently, the World Health Assembly (WHA) introduced the WHO Traditional Medicine Strategy 2014–2023, where impetus has been given to sharing knowledge, formulating policies, and regulating the quality, safety, and effectiveness of traditional and complementary medicine in the national health systems. It is a universal participatory approach where the government, healthcare practitioners, and consumers will have safe, cost-effective, and quality healthcare service through integrative therapeutic research [173]. Newer and strict guidelines for standardization are of utmost need. The approach has to be multidisciplinary combining pharmacology, biochemistry, analytical chemistry, microbiology, molecular and cell biology, genomics, proteomics, and bioinformatics.

9 Conclusion

As long as there have been people on earth, people have been using herbs. Herbal products and their formulation are as old as man which makes their user unavoidable especially where modern healthcare resources are scarce. These herbal remedies possess some pharmacological properties which can be harnessed to support modern and traditional health care. In recent years, interest in herbal medicine has grown exponentially which has led to an increasing number of unskilled people formulating herbal remedies solely for profit leading to a greater number of contaminants in herbal medicine products as well as many adulterated products in the sector. In the same vein, there has been a parallel growth in technology that may be used for the extraction of active ingredients using internationally standardized methods and best-known practices. Given that herbal remedies represent the first line of therapy for certain diseases for more than 80% of the world's population, prompt public health concerns about the safety of such remedies are justified. Mechanisms need to be put in place to guarantee that they are suitable for human consumption and free from microbial and other contaminants like toxins, microbial contaminants, heavy metals, dust, and pesticide residues. Plants are known to have essential phytochemicals with antimicrobial properties, but several factors must be taken into consideration, including the toxicity of the crude extracts, the extraction and purification processes, the dosage, and contamination in the different formulation and production phases. Additionally, many of the bacteria connected to herbal remedies have been known to seriously affect younger people, the elderly, and immune-compromised individuals. Some of the microbial contaminants have been implicated in several life-threatening illnesses. Therefore, it is necessary to implement more strategic quality control procedures to decrease the variety and density of microorganisms present in the herbal medications that have been created.

Contents

Abstract

According to the World Health Organization, 80% of people in underdeveloped nations and 60% of the global population, respectively, rely exclusively on herbal medications for their basic medical requirements. The public, policymakers, and healthcare experts are all becoming more concerned about the safety, standardization, effectiveness, quality, availability, and preservation of herbal products as a consequence of the rising demand for herbal medications. The most significant challenges in studying herbal medicine are incorrect plant identification and speciation, limited yields of chemically synthesized plant bioactive metabolites,

diversity of traditional techniques, and others. Thus, it is crucial to choose, reproduce, enhance, and study therapeutic plants and products using biotechnological technologies. Difficulties in plant species identification can be resolved with DNA-based technique and sequencing. Under some circumstances, the production of bioactive metabolites is possible, utilizing in vitro tissue culture methods. Pharmaceuticals made from proteins may be created using recombinant DNA methods that can alter metabolic pathways. Drug development from plant-based compounds may use the emerging fields of bioinformatics and genomics. This chapter covers an introduction of herbal medicine, biotechnological methods for producing herbal medicines, biotechnological methods for conserving herbal medicinal plant products, and bioinformatics methods as well as possibilities and problems.

1 Introduction

Common natural catastrophes, food scarcity, excessive resource consumption, environmental degradation, and other issues are the main issues the world is now dealing with and significantly impede the sustainable growth of human civilization. By

2050, the nearly 6.8 billion people who now live on the planet should have doubled and about 97% of the worldwide rise in population is due to this, which is concentrated largely in emerging nations [1]. So, the problem for the future is ensuring global food security, which will require tripling production of food over the next 50 years to accommodate demand from the world population [2].

Biotechnology application in plant breeding has brought about a positive effect almost entirely on high-demanding crops including rice, wheat, maize, soybean, potatoes, and sunflower across the globe [2]. According to estimates, 70–80 percent of people worldwide depend mostly on conventional medications, many of which are herbal. Traditional medicine includes herbal medicine (HM), often known as botanical medicines or phytomedicines. Herbal medicine (HM) is the use of herbs, herbal materials, herbal preparations, and completed herbal products that include active substances made from plant parts or other plant materials [3–31]. Plant parts used in the product may include seeds, berries, roots, leaves, bark, or flowers [32]. Many of the medications used in traditional medicine were first derived from plants.

Many modern medicines come from plants whose organs or parts contain chemicals that can be used as either therapeutics [33–45] or, in a more cutting-edge concept, precursors for the production of pharmaceuticals. One-fourth or more of prescription medications are thought to include plant extracts, active chemicals derived from or based on plant components, or both, while some of the most effective anticancer medications, like paclitaxel and vinblastine, are only made from plant sources [46–48].

The demand for herbal medicine is not only substantial but also rising globally. Several technological advancements have been made to improve the bioactive chemicals found in medicinal plants. By using methods like in vitro regeneration and genetic alterations, biotechnological instruments are crucial for the genetic improvement and genetic proliferation of medicinal plants. It may also be used to produce secondary metabolites in bioreactors made of plants. Therefore, this chapter discusses herbal medicine overview, biotechnological approaches for herbal medicine production, biotechnology approaches in conservation of herbal medicinal plant products, bioinformatics approaches, and opportunities and challenges.

2 Herbal Medicine Overview

Herbalism is a kind of traditional medicine or folk medicine that relies on using plants and plant extracts to treat ailments. One of the primary forms of life on earth is plants and herbs, which make up the majority of traditional *materia medica* across the globe. There are thought to be 350,000 plant species in existence (including ferns, bryophytes, and seed plants), of which 287,655 have been recognized as of 2004 [49]. Herbs, herbal materials, herbal preparations, and completed herbal products that include plant parts or other materials as active components are referred to as herbal medicine (HM), also known as botanical medicine, phytomedicine, or phytotherapy [50]. In herbal treatment, seeds, berries, roots, leaves, fruits, bark, flowers, or even whole plants are employed as plant parts. Before aspirin was developed from *Spiraea ulmaria*, which was already prescribed for fever and swelling in Egyptian papyri and recommended by the Greek Hippocrates for pain and fever, man was primarily dependent on crude botanical material for medical needs to maintain vitality and cure diseases [51].

Archeological studies have revealed that the use of herbal medicine dates back as far as 60,000 years in Iraq and 8000 years in China, despite written records about medicinal plants dating back at least 5000 years to the Sumerians, who described well-established medicinal uses for plants like laurel, caraway, and thyme [52–54]. Herbal medicine has been contested by practitioners of mainstream medicine since the development of western medicine (or "conventional" medicine) during the last century because of the lack of empirical proof in the context of modern medicine, despite its long history of successful usage. Due to the adverse effects of chemical medications, the absence of effective current treatments for a number of chronic illnesses, microbial resistance, and the unprecedented expenditure in pharmaceutical research and development (R&D), the use of herbs has increased recently [55]. For instance, the US Food and Drug Administration (FDA) has only authorized around 1200 new medications since 1950 [56]. As a consequence, during the last 40 years, both in developing and industrialized nations, the use of herbs and herbal products for health reasons has become more widespread [57]. Additionally, with the aid of contemporary science, technology, and ideas, multinational pharmaceutical companies have started to rediscover herbs as a potential source of fresh drug candidates and have updated their strategies in favor of the development and discovery of drugs from natural sources [58–60].

Nowadays, many "conventional" medical professionals do not hesitate to suggest herbs, herbal products, or complementary and alternative medicine (CAM) therapy to their patients for the successful management of certain disorders [61, 62]. According to a poll conducted in 2007, around 40% of adults and 11% of children used complementary and alternative medicine (CAM). On adult individuals both black- and white-skinned color users made up to 25.5% and 43.1%, respectively of the population [63]. Additionally, those with greater incomes and levels of education utilize CAM and herbal medications more often [64, 65]. In this regard, a 2012 research revealed that the use of complementary and alternative medicine (CAM) substantially linked with tertiary level of education, hoping to increase the usage among young patients with breast cancer disease [66]. The public's excitement for accepting CAM/CAMT is unaffected by the fact that we currently do not completely grasp the precise facts and processes behind most traditional medicines and/or how they prevent illness [67]. CAM and CAMT are widely practiced globally; however, they may all be categorized into one of the two groups: (1) nondrug-based CAM and CAMT and (2) drug-based CAM and CAMT [68].

Previous studies on promoting the use of organic and conventional plant material for advanced food or diet treatment and healthcare practices focused on various scientific findings and discovery of traditional herbal medicine and recent trends in pharmaceutical design, including different complementary and alternative medicines (CAM) which were conducted by Pan et al. [69–71].

3 Concept of Biotechnology

The term biotechnology can be defined as the application of biological components or phenomenon and living organisms and their derivatives to produce or modify products or processes for special utilization. Hence, conventional biotechnology has been in existence right from human history. Most of these traditional biotechnological applications are the brewing of beer, baking breads, breeding animals and food crops, etc. At the advent of molecular biology, a new dimension of biotechnology has emerged, which is commonly known as new or modern biotechnology. Modern biotechnology has brought tremendous breakthrough in global economy and society [72].

Modern biotechnology is the application of plant and animal genetic information for manufacturing of product and services. Genetic engineering alters the working of genes in the same genus or species to produce genetically modified organisms (GMOs). The development of modern biotechnology has been accelerated in the twentieth century, for example, the accomplishment of human genome mapping which identifies about 30,000 genes that encode the human hereditary features – a huge achievement in biology [73].

In the healthcare system, commercialized human insulin was first produced to meet the societal needs. Others are the treatment of genetic diseases and chronic disorders using gene therapy. The production of proteins with pharmaceutical values from cloning of mammals are all very significant exploits of modern biotechnology [72]. The genetic modification of plant and animals by implanting genetic materials referred as crossbreeding has been fruitful in agriculture, for example, crops like corns, oilseeds, etc. have been modified genetically [73]. Another application of biotechnology is the use of microorganisms to prevent, monitor, and remediate polluted environments. Biotechnology also enhances the manufacturing of vaccines, antibiotics, enzymes, etc. and the successful use of in vitro fertilization (IVF) in medicine, among others [74].

4 Biotechnological Approaches for Herbal Medicine Production

Field or wild plants in their natural habitats produce valuable bioactive compounds [75–77]. The availability and accessibility of these naturally derived products, however, limits the potential usage for the benefit of humanity. Utilization of medicinal plants has increased along with the secondary metabolite demand over the past years. Therefore, it is crucial to find new ways to produce high-quality plants and metabolites on a large scale. When it comes to homogeneous, controlled production, biotechnology offers a compelling substitute for whole-plant extraction, particularly when we consider the commercial demand. Additionally, regardless of the seasons and regions, it leads to high production of different herbal formulations [78–81]. By cultivating different plant tissues or whole organisms using in vitro techniques which can genetically alter the cells or organs to produce beneficial secondary metabolites, biotechnology provides an opportunity to profit from them [82]. There are several biotechnological techniques that may be used to increase the synthesis of secondary metabolites from medicinal plants, including embryogenesis, organogenesis, cell line screening, media modification, and elicitation. The sections that follow briefly go over several in vitro cultivation methods that may be utilized to create herbal medicines**.**

4.1 In Vitro Culture Techniques

See Fig. 1.

4.1.1 Micropropagation

The manufacture of high-quality plant-based medications has a lot of promise, thanks to in vitro plant reproduction [83]. With the use of micropropagation techniques, this process can be accomplished. Traditional plant propagation methods have several limitations when compared with micropropagation techniques which provides so many advantages [84]. The increase of plant production rate has been made possible due to micropropagation. Moreover, the techniques produce materials that are free from pathogenic microorganisms. Several medicinal plants can be known to micropropagate [85–90].

According to reports, a variety of conditions may affect how well certain medicinal plants can be propagated in vitro [91–94]. The plant hormones cytokinins with auxins can affect the growth rate of several medicinal plants' shoots. The compound 6-benzylaminopurine (BA) can increase the growth rate of *A. belladonna*'s plant

Fig. 1 In vitro culture techniques

with higher concentration of 1–5 ppm according to Benjamin et al. [95]. Using 1.0–5.0 mg/l of kinetin, Lal and Ahuja [96] discovered fast rate of multiplication of *P. kurroa*. Moreover, the regeneration of several plantlets from male medicinal yam using florescence on 13.94 mM kinetin-enriched media has been shown [97]. Using 2.2 mM of thidiazuron (TDZ) medium can produce higher proliferation of *N. foetida* [98]. In line with the above, the plant hormone cytokinin is very significant for shoot proliferation in a lot of genotypes but with the addition of auxin concentrations can increase the rate of shoot proliferation [99–101].

The use of micropropagation methods for medicinal plants assists breeders in many ways since it makes it possible, as demonstrated in Fig. 2.

The term "micropropagation" refers to the tiny branches or plantlets that are initially generated by this form of plant multiplication. This process offers a quick and dependable way to produce genetically pure plantlets. This is an important aspect of commercial plant propagation made by plant tissue culture, and it has significant implications [102]. The development of vegetation and its multiplication from plant known as micropropagation includes numerous in vitro aseptic culture methods that allow plant components to be artificially cultured on nutritional media [103]. It is designed to support a range of growth patterns, such as plant regeneration, cell multiplication, and organ development. The idea of transforming plant cells to new plants is the foundation of micropropagation [104, 105].

Many plants have extremely poor seed germination rates, produce blooms and seeds only when certain climatic conditions are fulfilled, or take a very lengthy time to mature and multiply. Since this technique enables the conservation of a broad

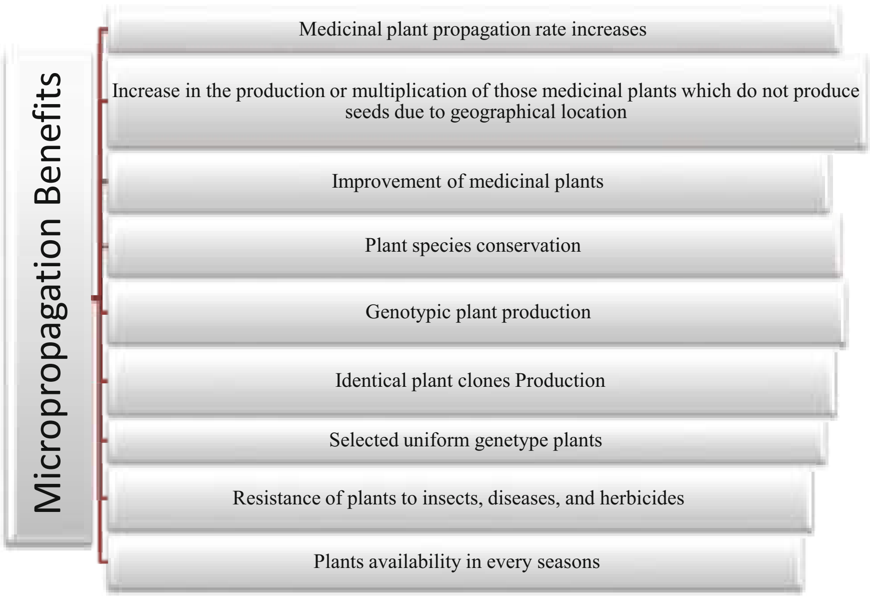

Fig. 2 Micropropagation benefits

genetic background, using seeds as the beginning material should be more appropriate for species that thrive in the wild [106]. Using the least amount of area and time possible, micropropagation provides a constant supply of therapeutic plants [107]. In order to cultivate and investigate the physiological behavior of isolated plant organs, tissues, cells, protoplasts, and even cell organelles under carefully regulated physical and chemical circumstances, micropropagation has now become a well-established technology [108]. Using in vitro techniques to preserve plant material has several benefits over keeping live collections in field condition [106]. Figure 3 illustrates the benefits of micropropagating medicinal plants.

Basic requirements are met by plant genetic resources, which also aid in finding solutions to issues like hunger and poverty. The most significant and necessary fundamental raw materials for crop development programs' present and foreseeable future demands are plant genetic resources. A number of factors, such as habitat fragmentation, overexploitation (overgrazing and excessive harvesting), competition from exotic species (accidental and deliberate introductions), changes in land use (deforestation and land clearance), population growth, and climate change, are all contributing to the genetic erosion that is causing them to disappear. The growth of contemporary commercial agriculture and the substitution of contemporary hybrid plant varieties for traditional farmer plant types during the last 40 years have been the primary causes of genetic loss. The circumstance justifies stepping up efforts to

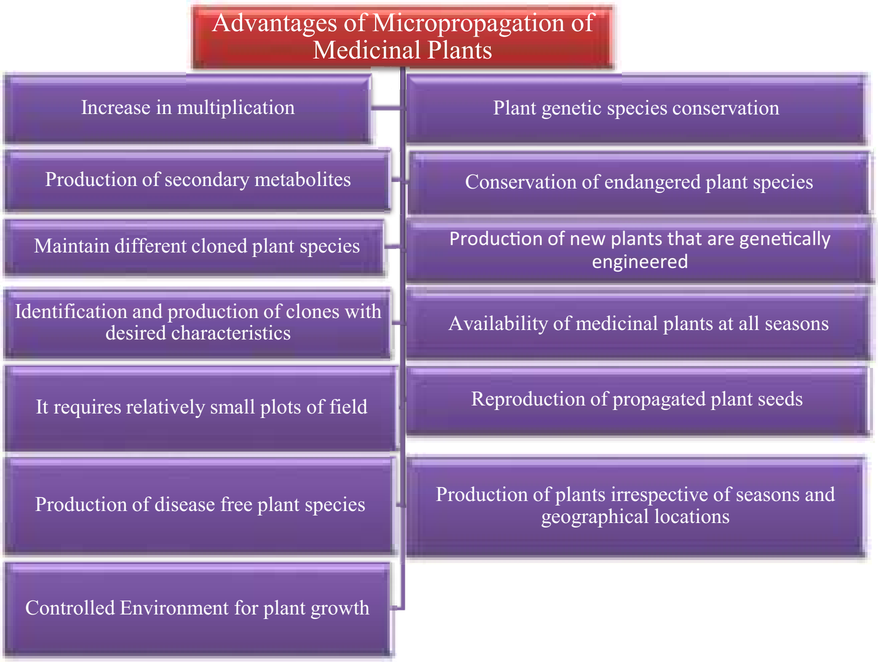

Fig. 3 Advantages of micropropagation of medicinal plants

create strategies for their germplasm preservation. We must protect them due to their critical relevance for the current and the new generations to come [109].

The management and conservation of plant variety have benefited greatly from improvement of biotechnology of plant breeding, particularly the ones relating to genetic engineering and tissue culture techniques. Nowadays, disease-free plant materials, special plants, and genetic variety may be preserved for short, medium, and long terms, thanks to biotechnological approaches employed to conserve endangered, uncommon, decorative, medicinal, and forest species. In an aseptic setting, cell culture methods enable the fast growth of plant parts. In vitro plant culture system has been widely established for regeneration and propagation of more than 1000 distinct vegetative species which include several scarce and vulnerable species, using two alternate morphogenic processes: shoot organogenesis or somatic embryogenesis.

Micropropagation is a technique for multiplying plants by cultivating extremely minute components. The preservation of these priceless genotypes is essential since the widespread harvesting of medicinal plants from their native habitats is depleting plant resources. Such germplasm may be effectively preserved by micropropagation. Another strategy to increase the plant's ability to produce drugs is genetic improvement [110].

4.1.2 Organ Cultures

Depending on the outcomes, the best approach should be chosen. Dedifferentiated (callus) cultures are not preferred for medicinal plant species which are localized in specialized tissues, although organogenic cultures that have been generated would be beneficial. Redifferentiation is often linked to better secondary metabolite production in in vitro settings [111]. This is likely caused by the emergence of complex, metabolically more capable cells and tissues. Even though it is nonmorphogenic, it may exhibit some cell-level differentiation and, as a result of coevolution, mimic the biochemistry of redifferentiated cells [112]. According to findings on *A. annua* and *A. indica*, redifferentiation was necessary for the formation of compounds since the production of artemisinin was extremely low in uniform callosity cultures [113].

In addition, it was shown that organogenesis was a necessary condition for *Ruscus aculeatus* to produce steroidal saponin. Similar findings were reported with the production of *picroside* in *Picrorhiza kurroa*, where it was shown that the metabolite only appeared in the redifferentiated cultures which cannot accrue in uniform callosity culture. Moreover, Berkov et al. [114] showed that tissue differentiation and alkaloid production are tightly connected in *Pancratium maritimum*.

There were attempts for regeneration of a whole plant tissue such as roots or shoots in favorable conditions from explants or through an intermediary callosity stage, due to the observation of higher production of secondary metabolite from well-arranged plant cells. As might be predicted, these regenerative cultures generate secondary metabolite patterns that are comparable to those of the parent plant cultivated in the field, with the extra benefit of increased metabolite synthesis. Another benefit of utilizing structured cultures is that they produce secondary metabolites more steadily when compared with uniform cultured tissues in either suspension or callosity cultures [82].

4.1.3 Callus Cultures

A uniform group of tissues or cells derived from explants implanted in vitro inside of a media with comparatively greater auxin concentrations or a mix of auxin and cytokinin concentrations at equal levels is referred to as a callus culture. Plant parts that are made of beneficial bioactive compounds can be therapeutically utilized after plant extraction process using in vitro techniques. High-performance liquid chromatography and liquid chromatography-mass spectrometry techniques can be employed for identification and quantification of therapeutic compounds from various plant species [113].

There are several biotechnological techniques that may be used to increase the synthesis of secondary metabolites from medicinal plants, including embryogenesis, organogenesis, cell line screening, media modification, and elicitation. The sections that follow briefly go over several in vitro cultivation methods that may be utilized to create herbal medicines.

4.1.4 Suspension Cultures

With the effective development of cell lines capable of synthesizing secondary chemicals in cell suspension cultures in high yields, a breakthrough in cell culture technology was achieved. This strategy has attracted corporate attention during the last several decades. The idea of the synthesis of plant tissue totipotency means that different tissues or cells in a culture media preserve the full hereditary information for producing the variety of metabolites in the entire plant, which is the foundation for the technique of using plant cell suspension cultures for the production of secondary metabolites [115].

By inoculating them into liquid medium, established callus cultures are transformed into cell suspension cultures. After that, the cultures are maintained in glass flasks while being constantly shaken by rotatory shakers; ultimately, it may be moved into a dedicated fermentor. Since oxygen and nutrients are more effectively mixed under shaking conditions, cells in suspension cultures develop significantly more rapidly than those in semisolid medium. The implementation of plant tissue technology for the generation of secondary compounds depends on the productivity of suspension cultures. There are a number of methods that may be utilized to boast the synthesis of bioactive compounds in in vitro cultures, including altering the environmental and media characteristics, choosing high multiplication clone cells, feeding precursors, and elicitation [113].

4.2 Genetic Transformation and Production Technology of Medicinal Plant Products

In plant production of crops, recombinant DNA technology or biogenetics plays very vital roles in their proliferation. The technology can be used to solve several agricultural problems that traditional plant breeding cannot able to solve. There have been improvements recorded by recent research of bioactive compound productions using recombinant DNA technology. At present, using *Agrobacterium*-assisted methods has able to generate about 150 plant species from nothing less than 35 plant families of different types of plants [116–119].

Two plant diseases, namely, hairy root and crown gall tumor are caused by *A. tumefaciens* spp., a gram-negative soil bacteria related to *A. rhizogenes*. While there have been examples of monocotyledonous plants being infected, these species, which are members of the *Rhizobiaceae*, mostly alter or change dicotyledonous plants [120–125]. The genetics involved in the production of the plant hormones (cytokinins and auxins) tumors and opiates are two different types of T-DNA genes.

Several plants especially dicotyledonous have frequently used *A. rhizogenes* for genetic transfer. This gram-negative bacteria promotes infections in plants which results in the multiplication of different branched roots, or "hairy roots," at the site of the plant infection [125]. The study was focused on the use of hereditary plant modification and transformation applying the soil gram-negative bacterial *A. rhizogenes* to enhance the production of the beneficial bioactive compounds, which are synthesized in the mother plant roots.

Various hairy roots that have been converted often show greater production rates and replicate the biochemical mechanisms that exist which makes it active in the regular root products. Many therapeutic plant species have claimed to pass through several genetic changes. According to Naina, Gupta, and Mascarenhas [126], genetically modified *Azadirachta indica* plants were successfully regenerated with the use of *Agrobacterium tumefaciens* strain that included variant of pTi A6 plasmid [126–128]. Using different explant leaves, agrobacterium-assisted modification of *Echinacea purpurea* was shown [129]. A very important technique necessary for making high yield of bioactive compounds is the application of genetic transformation or recombinant DNA due to its efficacy and production of hormone-free growth conditions.

Artemisia annua medicinal plant's root culture process was created via an infectious microorganism *Agrobacterium rhizogenes*, and 4.8 mg/L of artemisinin concentration is ideal for its formation [130]. Using *Agrobacterium rhizogenes*, Giri et al. [131] stimulated the hairy root growth in *Aconitum heterophyllum* [131]. Pradel et al. [132] created a method for growing altered plants from *Digitalis lanata* root explants. They tested several natural *Agrobacterium rhizogenes* strains for their ability to produce secondary products from transgenic plants and hairy roots. The altered hairy roots contained more anthraquinones and flavonoids than the untransformed roots did, according to their findings. It is stated that an effective method for creating plant cultures of the some transgenic plants, namely, *Eschscholzia californica* and *Papaver somniferum*, utilizing *Agrobacterium rhizogenes* has been developed [133]. After being transformed by *Agrobacterium rhizogenes*, the hairy roots of *Atropa belladonna* produced tropane alkaloids, according to Bonhomme et al. [134]. According to Argolo et al. [135], the roots of *Solanum aviculare* that have been altered by *Agrobacterium rhizogenes* control the formation of solasodine. The sesquiterpene artemisinin production of *A. annua*'s converted roots has been shown by Souret et al. [136] to be higher than that of entire plants. Shi and Kintzios have shown how *Agrobacterium rhizogenes* genetically modified *Pueraria phaseoloides*, producing puerarin in the hairy roots [137]. Puerarin concentrations in hairy roots increased to 1.2 mg/g dry weight, which is 1.067 times higher than concentrations in untransformed plant roots. As a result, these altered hairy roots have enormous promise as a reliable supply of secondary metabolites for commerce.

4.3 Bioprocess Production Technology of Secondary Metabolites

Plant cells are said to be particularly sensitive to shear pressures in the literature, calling for the usage of specialized low-shear fermentor, such as air lift fermentor. Such bioreactors are uncommon in industry, because most operations take place in stirred-tank vessels. Since it is the least expensive process unit, such a bioreactor is preferred for plant cell cultivation [138]. Recent laboratory investigations, among others, on the shear sensitivity of plant cells have shown in reality that they are generally fairly shearing stress resistant [139]. This is corroborated by the several large-scale procedures using plant cell cultures, such as the manufacture of shikonin that has been documented. Even plant cells have been grown in 60-meter agitated tanks [140]. Given that technology is practical, what about the economy? Many studies have been published on this [141]). A price of 1500 US dollars/kg was determined using an annual production rate of 3000 kg/year of a chemical generated by a cell culture at a level of 0.3 g/L. Price increases to 430 $/kg with a factor of 10 (3 g/L) increase in production [142]. A fed-batch method of processing was used in both situations. While these costs are exorbitant, other natural products (such as vincristine, vinblastine, and Taxol) are considerably more expensive [143]. Nevertheless, in plant cell cultures, the majority of valuable specialty chemicals are generated at insufficient amounts [144]. So, their output must be raised to enable an industrial process [145].

4.4 Molecular Genotyping Method

While physical traits will continue to be used in plant identification to determine the family, genus, and species, uncertainties at the level of the species and strain may be cleared up by contemporary genotyping techniques. The fundamental premise is that each species and, in certain cases, each creature have a unique DNA sequence that may be used to unmistakably identify it**.** With the development of genome technology, DNA sequencing has become automated and practical on a wide scale [146]. Yet, it is not practical to routinely study whole plant genomes. Targeted, recognized, and sequenced diagnostic genes or fragments may be very specific. In these situations, the polymerase chain reaction (PCR), which enables the targeted amplification of DNA fragments, is often utilized. After the diagnostic segment has been located, it is possible to design and create particular primers to employ in its amplification. In fact, these methods are now often employed to diagnose bacterial, viral, and parasite illnesses in animals [147].

The use of DNA fingerprinting may reveal subtle variations among species. The restriction fragment length polymorphism (RFLP) is a well-known technique for DNA fingerprinting. In describing the plants, genomic or chloroplastic DNA is obtained, digested with certain restriction endonucleases, separated by agarose gel electrophoresis, blotted onto nitrocellulose paper, and probed with radiolabeled particular gene probes. Each distinct species is given a distinctive pattern of horizontal lines. After distinct DNA bands have been removed and sequenced, the organism (or plant) in issue may be identified without a doubt. The amplified fragment length polymorphism (AFLP) analysis is a useful RFLP modification [148].

The PCR used in the randomly amplified polymorphic DNA (RAPD) technique uses a set of primers that are chosen at random. They create DNA fragments that are specific to the target organism by binding to a number of complimentary places along the genome. The identification and speciation of medicinal plants is expected to be made simpler by a thoughtful mix of conventional morphological identification with DNA profiling, as described above. For the detection of plant pathogens and specification, unique monoclonal antibodies may be generated in addition to DNA-based techniques [148].

A feasible approach would be to first determine a plant's medicinal value before developing a DNA-based test for it. If the bioactive plant product is a protein, this technique could specifically target the gene that codes for the protein. The technique may also concentrate on the genes that code for important enzymes in a secondary metabolite's synthesis pathway.

5 Biotechnological Approaches for Conservation of Medicinal Plant Products

Biotechnology is rapidly becoming a crucial technology for sustainable environmental management and preservation [149–151]. Almost every element of human existence has been impacted by biotechnological advancements, including food, fuel, cosmetics, medications, and drinks. Most significantly, biotechnology-based approaches provide a consistent supply of natural products and raw materials for the food, pharmaceutical, and cosmetic sectors [152]. Prescott-Allen and Prescott-Allen proposed a methodical notion of sustainability. They contend that both people and the ecology are interconnected and reliant on one another. So, in a conceptual sense, the link between humans and the ecology around them expresses the core of sustainable development. They went on to say that it is believed that a society is sustainable when both the status of the environment and the state of the population are adequate or improving. They came to the conclusion that the system only becomes better when both the ecological and human situations get better [153].

Various in situ and ex situ approaches (including in vitro methods, botanical gardens, plant banks, GenBank, gene sanctuaries, and seed banks) have been proposed for the conservation of critically endangered plant species in order to provide medicinal plants or medicinal plant-based raw materials in a sustainable manner [154–156]. Maintaining genetic variety is crucial for protecting plant genetic resources. Ex situ and in situ methods are used to save plant genetic material. The in situ technique involves preserving plant species and/or populations in their native environments, where they may develop, thrive, and breed. Ex situ conservation, on the other hand, focuses on preserving plant species' genetic material under controlled circumstances [157, 158]. At nurseries, a large number of plants are produced by the traditional processes of cutting, budding, layering, and/or grafting. Yet, biotechnological techniques like genetic engineering, metabolic engineering, and micropropagation are particularly suitable for species that are challenging to reproduce in vivo [159].

Hence, preserving medicinal plants in situ would not be an efficient and successful technique for their preservation and growth. According to Krishnan et al. [160], judicious use of propagating biotechnology tools in plant conservation programs is a need for success (in the sustainable utilization of therapeutic plants) and serves to supplement the ex situ measures already in place. Since it will be useful in creating management strategies, preserving their genetic variety, and guaranteeing their long-term existence, the comprehensive study of the genetic diversity of uncommon and endangered plant species is crucial [161]. Micropropagation, mycorrhization, genetic modification, and the creation of DNA banks are biotechnological strategies for the long-term supply and preservation of medicinal plants [158, 162]. Using biotechnological methods, any group of plants may be conserved.

5.1 Cryopreservation

Cryopreservation, which involves freezing biological material or storing it in a cryogenic environment at a very low temperature, is one of the key biotechnological methods in the conservation of plant species [163]. When more conventional methods like seed banking and vegetative propagation are ineffective for the particular plant species, cryopreservation is utilized to preserve plant germplasm. Hence, liquid nitrogen(-196 °C) is used to retain plant germplasm generated from in vitro for long-term conservation [164].

The preservation of surviving individuals is regarded to be of the utmost significance for vulnerable and endangered species since they either generate few or no viable seeds or are dormant [165]. Such problematic species need to be preserved by cryo-collections [166]. When necessary, material may be easily removed and reinitiated, reestablishing ideal clonal lines. Cryopreservation provides the effective and safely long preservation of species without compromising viability [167]. Plant materials are preserved for future use, including cells, tissues, gametes, oocytes, organs, DNA samples, etc. [168]. One of the most significant conservation strategies is cryopreservation, which has been used effectively to preserve a variety of medicinal plants. Examples of preserved species are *Atropa belladonna*, *Digitalis lanata*, *Hyoscyamus* sp., and *Rauvolfia serpentine* [163]. Some institutions have already made steps to conserve medicinally significant yet endangered plants. For instance, the Kings Park and Botanic Garden in Australia uses the cryopreservation strategy to conserve over 110 succession of scarce or vulnerable plant species [169].

Similar to this, more than 1200 accessions from 50 distinct plant species are kept at the National Bureau for Plant Genetic Resources (NBPGR, New Delhi, India) [170]. The similar method has been used to preserve the shoot tips of *Picrorhiza kurroa*, an endangered plant with significant medicinal value [168]. *Dioscorea bulbifera* embryogenic cultures were cryo-preserved utilizing the encapsulation-dehydration method. The subculturing after cryopreservation revealed a 53.3% recovery in the development of the embryogenic culture [171]. These investigations unmistakably shed light on the value of cryo-techniques in the preservation of priceless medicinal plants [159]. Cryopreservation approaches have, however, only received a very small amount of study; hence, further work in this field is required to effectively use this technique or strategy for the preservation of medicinal plants.

6 Bioinformatics Approaches

The current pharmaceutical business has also made use of the information from ancient systems of plant-based treatments. So, based on the ethno-medicinal information, there is a huge potential for the identification of novel medications from plants [172, 173]. Almost one-third of medications now on the market are made from plant-based natural ingredients [174]. While research on plant-based cures is behind (particularly when contrasted to the focus in creating synthetic pharmaceuticals for commercial use), they offer a great deal of promise to advance contemporary medical therapies [175]. This could be in part due to the time- and money-consuming nature of traditional plant drug development processes [176]. Yet, it would be beneficial to do further study into the cultivation of therapeutic plants and herbal medicines. The literature and resources in this field are often dispersed, which makes it difficult to quickly take use of the knowledge about medicinal plants and the manufacture of herbal medicines that is already accessible.

The diversity of chemicals may be analyzed computationally using a variety of methods. These methods have been crucial to computer-aided drug design [177]. To keep up with the increasingly demanding drug needs, the area of pharmaceutical discovery and design from therapeutical plants necessitates the implementation of the methodologies to bring about speedier and more effective advancement. Huge amounts of data produced by molecular biology-based procedures may be analyzed and interpreted utilizing a variety of vital tools provided by bioinformatics. These methods have become more important in data analysis and integration to infer information from a whole systems perspective as high-throughput techniques have advanced. A deep examination of metabolomics, genomic, and proteomic data is necessary to improve our knowledge of the biological processes connected to plants. Genetic information and its mechanism identifications can be linked to significant production of biologically active compounds from therapeutical plants which have been facilitated by the use of bioinformatics methods [178].

Coexpression networks may be generated from transcriptome data using bioinformatics techniques, potentially pointing to new genes in closely related plant species. Particularly, the use of comparative genomes offers a foundation for information sharing across various species. For instance, a coexpression network was developed using transcriptome data from barley. Moreover, subnetworks (or "modules") linked with biological processes were developed using the results of coexpression investigations, with a focus on finding modules connected to drought stress and cellulose production. It has been shown that this genome-scale sequence comparison reveals numerous *Triticeae* species-specific genes connected to certain regulatory networks [179].

A useful method for determining putative functional actions of genes is pathway analysis. A framework for pathway study of secondary metabolites from many species is provided by the Kyoto Encyclopedia of Genes and Genomes (KEGG) resource [180]. Bioinformatics plays a crucial function in aiding the metabolic pathways of processes knowledge in light of the many advancements in "omic" technology. Many possibilities exist to research metabolic pathways, thanks to the homogenization of metabolomics and transcriptomic information using knowledge discovery in data (KDD) tools [181]. In order to find potential genetic makeup metabolite involved in the manufacture of alkaloids and terpenoids, Rischer et al. [182] examined a "gene-metabolite coexpression network" of the therapeutic plant *Catharanthus roseus*. The ability to examine metabolic regulation of nonmodel plants with potential medical utility has therefore been shown by integrated gene-metabolite expression analysis. Bioinformatics offers vital tools for processing large amounts of data produced by high-throughput methods. These methods have made it feasible to identify candidate genetic processes that are rapt in the production of secondary metabolites in therapeutic plants, in particular. Bioinformatics techniques may be crucial for combining disparate bits of evidence into coherent hypotheses, creating possible leads for experimental validation [173].

7 Opportunities and Challenges

The use of traditional medications and the significance of its business are both rapidly expanding and pervasive. The practice of herbal medicine, which dates back thousands of years, is now advancing quickly and experiencing something of a revival around the globe, especially in affluent nations. The majority of the components in herbal medicines come from wild plants, and as a result of habitat loss, climate change, and rising demand for medicinal herbs, many species are under threat. Wild resource extraction conducted without discrimination has resulted in genetic diversity loss, declining populations, local extinctions, and habitat devastation [3].

For an optimum production of therapeutic plants, it will provide a workable conserving approach and gets rid of issues with misidentification, genetic and phenotypic variability, extract variability and instability, poisonous components, and contamination that are often present in herbal extracts. Cultivation may also result in homogeneous high-quality output and an optimized yield. But, the planter must choose which specific species to produce in a market that is always changing and fashion-sensitive. Consequently, another significant barrier to the effective commercial production of therapeutic plants is the difficulty in determining which extract will stay marketable [154].

Despite the fact that many of the plants utilized in traditional medicine are grown, the vast bulk of these plants are obtained from the natural resources. Due to poor germination rates, a lack of high-quality planting materials, or certain ecological needs, producers of herbal plants have several challenges. The primary obstacles to growing herbal plants are a lack of understanding of the precise needs for pollination, seed germination, and growth. Low germination rates are typically caused by fungus or mechanical damage, but they may be readily addressed with better seed treatments and by maintaining ideal storage conditions. However, employing controlled settings, such as hydroponic systems, it is simple to produce challenging herbal plants on a commercial scale [97].

The fact that primary metabolites are key component in the traditional medication which is generated relatively in little amount of the plant species presents another significant problem in the development of herbal medicines. This is clearly shown that plant cells mostly generate the bioactive components in modest amounts as secondary metabolites. This results in the destruction of several herbal plants in order to produce a single medicine. Nowadays, however, this wasteful harvesting method may be readily avoided by using contemporary methods and their modifications genetically. The commerce in medicinal plants is growing yet mainly unregulated in the modern world. Many current harvesting methods are not sustainable, endangering both the populations of medicinal plants and their ecosystems as well as the means of subsistence for individuals who participate in their gathering. It is now up to us as individuals, as well as the government, to discover effective, worldwide answers [155].

8 Conclusion

Nowadays, the oldest and most popular kind of medicine in the world is herbal. In both developing and developed countries, a significant section of the population still depends on herbal medicine as their main form of treatment. As a consequence of this rising demand, policymakers, medical experts, as well as the general public have concerns regarding the safety, standardization, effectiveness, quality, availability, and preservation of herbal products. The most significant challenges in studying herbal medicine include incorrect plant identification and speciation, low yields of chemically prepared plant bioactive metabolites, variability of traditional protocols, and others. Due to the effective application of in vitro technique for bioactive compound production in conjunction with other techniques such as in vitro regeneration and hereditary transformation, the use of biotechnological tools is crucial for the multiplication and genetic enhancement of the medicinal plants. An important set of tools for creating effective and focused searches for herbal medicine practice may also be provided by bioinformatics methodologies. Combining bioinformatics techniques may open the door to a new era of herbal medicine use that will greatly advance the field.

Abstract

Herbal remedies have been practiced all over the globe for many years, but the prevalence of their use in India is significantly based on nanotechnology; it is necessary to make concessions about the drug distribution techniques observed. Herbal medicines have gained popularity as a therapy option due to their range of applications and lesser likelihood of adverse responses in comparison to traditional pharmaceuticals. This is because herbal medications can be used to treat various conditions. It is essential to develop novel nanodrug delivery to circumvent such low bioavailability, in vivo stability, liquid insolubility, intestinal uptake, and unspecific site of action. The incorporation of nanotechnology as a novel drug delivery system (NDDS) into conventional methods of medical practice has the potential to increase the efficacy of herbal medications in the treatment of chronic illnesses such as cancer and other fatal diseases. In order to effectively produce herbal medicine work based on nanotechnology, it is necessary to make concessions with regard to drug distribution techniques based on nanotechnology. This is essential whenever observed as a component of the global economy. This chapter emphasizes the present issues that herbal medicine practitioners are facing, as well as the ways in which these challenges might be overcome by utilizing new solutions.

1 Introduction

The field of science and engineering known as nanotechnology is concerned with designing, synthesizing, measuring, and implementing devices and materials whose lowest functional organization appears on the nanoscale in any one of their dimensions (a trillionth of a yard) [1, 2]. A vast area of science called nanotechnology has recently made major advancements and is rapidly growing [3–6]. Due to their perceived efficacy compared to contemporary conventional medications and reduced cost, herbal medicines are growing in popularity worldwide. They have considerable potential for providing treatment, sustaining and enhancing health, and avoiding and curing several illnesses [7, 8]. However, many of these physiologically active phytochemicals have some drawbacks, like sluggish reception and distribution rates and typically poor target selectivity. Poor bioavailability results in lower cellular function. Furthermore, substantial quantities of these phytochemical compounds must be consumed to have the desired effects, and some of these compounds are unstable and highly vulnerable to acidic environments [9–12]. It is challenging to apply them therapeutically because of these restrictions.

Herbal medicines numerous diverse ingredients all work to treat diseases concurrently [13]. For phytotherapeutics to increase patient cooperation and eliminate the need for repetitive administration, a systematic approach must introduce the processes gradually. This requires the development of innovative drug delivery systems (NDDSs) made especially for plants to become a scientific fact. Innovative drug distribution techniques will reduce the need for repeated administering, which is required to counteract noncompliance. Among other things, lowering the toxic effects of the medication and raising the pharmacokinetics will also enable the achievement of higher therapeutic benefits [14, 15].

Nanotechnology-based drug carriers have the potential to overcome the many obstacles that plant medicines face, including enhancing their plant chemicals and their biological function and bioavailability. One strategy that has the potential to develop into a cutting-edge new technique that will improve the effectiveness of the usage of phytotherapy in medicinal products is the incorporation of nanoscience into phytochemical components. Developing and implementing a dependable and risk-free pharmaceutical distribution system is a significant objective of this study. Recent developments in nanotechnology have reignited interest in the creation of herbal medications. Some of the techniques proposed as possible means of substance transport include phytosomes, nanomaterials made up of polymeric material, solid-state nanoparticles of the lipids (SLN), the nanostructured transporters of triglycerides, and nanoemulsions. The pharmacokinetics and biochemical effects of herbal medicines are anticipated to improve with the implementation of nanotechnology [7, 11, 16, 17]. This is because a significant number of drugs have had their pharmacokinetic properties altered and improved by the use of nanoparticles. This chapter's primary goal is to briefly overview recent advances in creating medicinal product formulations using nanotechnology that boost the activity of herbal components.

1.1 Background of Nanotechnology

The term "nano" originates from the Greek term for "dwarf." One nanometer (nm), often known as a billionth of a yard, is equivalent to approximately six atoms of carbon or ten water molecules. Compared to the width of a red blood cell, which is only about 7000 nm, a nanometer is more significant than an atom, yet many substances, including specific proteins, can be larger than a nanometer [18]. The philosophical underpinnings of nanotechnology were first introduced by Richard Feynman, a physicist, in his 1959 talk "There's Plenty of Space at the Bottom." In the words of Q. Feynman, who looked into the concept of impacting material at the size of distinct atoms and molecules, the complete *Encyclopedia Britannica* could probably fit on the tip of a pin. Feynman anticipated that shortly, we would be able to observe and manipulate materials at the nanoscale. The term "nanotechnology" was created in 1974 at University of Tokyo by scholar Norio Taniguchi to characterize the ability to develop materials at the nanoscale precisely. During this period, the primary driver of miniaturization was the electronics sector, which tried to create methods for producing smaller (and subsequently faster and more complex) electrical gadgets on silicon chips. IBM utilized another technique known as electron beam lithography in the early 1970s in the USA to produce nanoparticles and devices with dimensions ranging from 40–70 nm.

1.2 History and Development

Natural ingredients, particularly plants, have always been the cornerstone of healing human illnesses. Conventional treatments and medicine still provide the philosophical underpinnings for advancing contemporary medicine [19, 20]. Long before known history, people worldwide used plants for medical purposes, particularly in medieval China, Egypt, America, South Africa, and India. This practice may even be traced back to prehistoric times. The first efforts at extracting and altering plant components date back to the early nineteenth century, thanks to advances in chemical research [19, 21]. For a long time, herbal remedies were neglected to create innovative formulations due to a lack of research backing and processing challenges such as standardization, extraction, and identification of specific medicinal components in complicated polyherbal systems. This was due to the fact that herbal remedies are notoriously difficult to work with. Research on current phytopharmaceuticals, on the other hand, not only meets the scientific standards for herbal treatments in modern medicine but also paves the way for the creation of innovative formulations such as nanoparticles, microemulsion matrix frameworks, solids dispersion, liposomes, and SLNs, among other things. Curcumin can now be used alone or with other chemotherapy medicines like paclitaxel, thanks to creating aqueous nanogels, nanotubes, and nanomicellar systems [22].

1.3 Nanoherbal Medication Delivery Method

Over the past 20 years, much attention has been placed on creating an innovative medication delivery system (NDDS) for herbal medicines. Humans have used plant-based medicines to cure various illnesses for a very long time. However, these phytomedicines have many limitations due to issues with their durability and fat solubility. Different botanical medicines are being created with herbal components to solve these issues. Such herbal medication delivery methods may one day be used to handle problems with plant-based therapies by enhancing their activity. Such delivery mechanisms facilitate the discharge of active substances into the body and are simple to produce [23]. Other studies have examined the various applications of NCs in nanomedicine and the challenges and new opportunities in the field [24]. As a result, to fight the effects of chronic illnesses like asthma, diabetes, cancer, and others, the traditional medical system must adopt nanocarriers as a distinctive nanodrug delivery technology. Some nano-based drug delivery methods currently under investigation include liposomes, dendrimers, polymer nanocarriers, synthetic subatomic particles, nanocapsules, nanospheres, and nanogels [25] (Fig. 1). Some of them have been used in clinical contexts and have received FDA approval, particularly for cancer treatment. Active and passive targeting are the two methods that have been applied to the use of medication distribution devices in cancer therapy. The final goal of these targeted methods is to reduce side effects while boosting drug accumulation in tumor tissue [26].

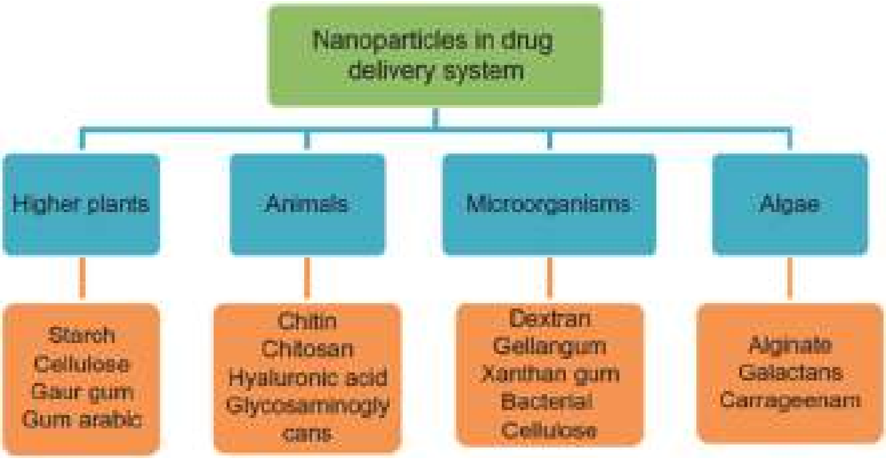

Fig. 1 The natural biopolymers that are utilized in the nanoherbal medication delivery system as well as the sources of these materials

1.4 Nanotechnology Applications in the Field of Medicinal Plants

Nanoparticles (NPs) are adaptable materials that may be employed in a wide variety of contexts; nevertheless, they have shown to be of particular utility in the field of nanomedicine, where they have been utilized in sensitive diagnostic procedures and to repair damage to tissues caused by extremely high temperatures, treatment with radiation enhancement, drug administration, and gene transport [27]. The metallic NPs-herb union may more effectively treat many pathophysiological ailments, such as cardiovascular disorders (CVD). Given the increasing incidence of CVD, research into plants and medicines derived from them with antioxidant, anti-inflammatory, anti-bacterial, and antihypertensive properties is crucial for further evaluating organically generated medicine's compatibility with people [28]. Investigating natural products and their prospective for use with NPs is also critical to grasp better current technical developments and the medicinal advantages of organically derived substances. The application of nanotechnology in the medical industry is gaining more and more favor, particularly for the delivery of medications. Pharmaceutical studies have employed nanomaterials to reduce the harmful adverse effects of medicines for millennia. Unfortunately, not all cancer treatments reach the cancerous site without harming nearby healthy tissue and organs [29]. To successfully treat cancer, nanotechnology might be able to directly deliver therapeutic compounds by beating biological obstacles. The particulars of metallic NPs elements, including nanoparticles of silver (AgNPs), which have produced much study because of their degree of cytotoxicity, offer novel possibilities for cancer treatments [30]. According to the research, AgNPs could be used as a cancer-fighting weapon, a medical breakthrough.

A very safe technique for the development of nanomedicine is the nano-encapsulation of medicinally important drugs derived from plants in NCs, which include liposomes and micelles, which are synthesized or nanoparticles that are solids of lipids (SLNs), dendrimers of lipids or albumin nanocapsules, nanovesicles, nanogels, nanosuspensions, and nanoemulsions [31]. The contemporary nanoencapsulation of pharmaceuticals method reduces drug toxicity by enabling the appropriate quantity of drug compounds to be loaded within the NCs. Numerous MAPs generate essential oils with antibacterial properties that are effective against various pathogens, including bacteria, viruses, and fungi. The two significant factors of critical oil responsiveness are the features of the functional categories present in the oils and the perspective of the essential oil. Because they can promote membrane permeability, disrupt cellular metabolism, and do other things, essential oils made from MAPs are believed to be helpful against a wide range of infections, liberate important intracellular components, and change the enzyme kinetics of pathogens [32]. These variables eventually cause the cell walls of the bacteria to deform. The literature provides details regarding essential oil usage in studies conducted in vitro; however, multiple research investigations utilizing these kinds of oils fell short of presenting precise information regarding their chemical structure and the mechanisms of action, clouding the reproducible nature and competence of their discoveries. With the above prospects, future studies should focus on deciphering extracted oils, chemical constituents and molecular processes. Biopharmaceutical companies are frantic for ecologically friendly alternative drug molecules for treating bacterial and human metabolism disorders. Plant essential oils that have been extracted may be a source of antibacterial agents, according to in vitro studies, and may thus play a vital part in curing many kinds of pathogenic microbes by introducing new medicines.

2 Synthesis of Nanoparticles

2.1 Polymer Nanomaterials

Polymer nanoparticles can be either solid or liquid, ranging from 10–1000 nanometers. Polymer nanoparticles are also known as nanospheres and nanocapsules. They can be produced from prefabricated polymers or straight from monomers through polymerization. Fluid evaporation, salting out, dialysis, rapid growth of extremely critical solutions, and vaporization are all used [33]. When selecting a preparation process, the kind of polymeric material, the scope of usage, the size requirement, and other parameters are all considered. Polymeric nanoparticles had displayed successful therapeutic activity using any of these techniques. Figure 2 depicts a conceptual model of polymeric nanoparticle synthesis.

2.2 Magnetic Nanomaterials

Metal complexes like FePt and CoPt were used in addition to pure metals like CO, Fe, and Ni in the creation of the magnetic nanoparticles [34]. Using nanomaterials with magnetic properties makes producing particles with dimensions of about 3 nm feasible. Nanoparticles are several hundred atoms, enabling us to create media for

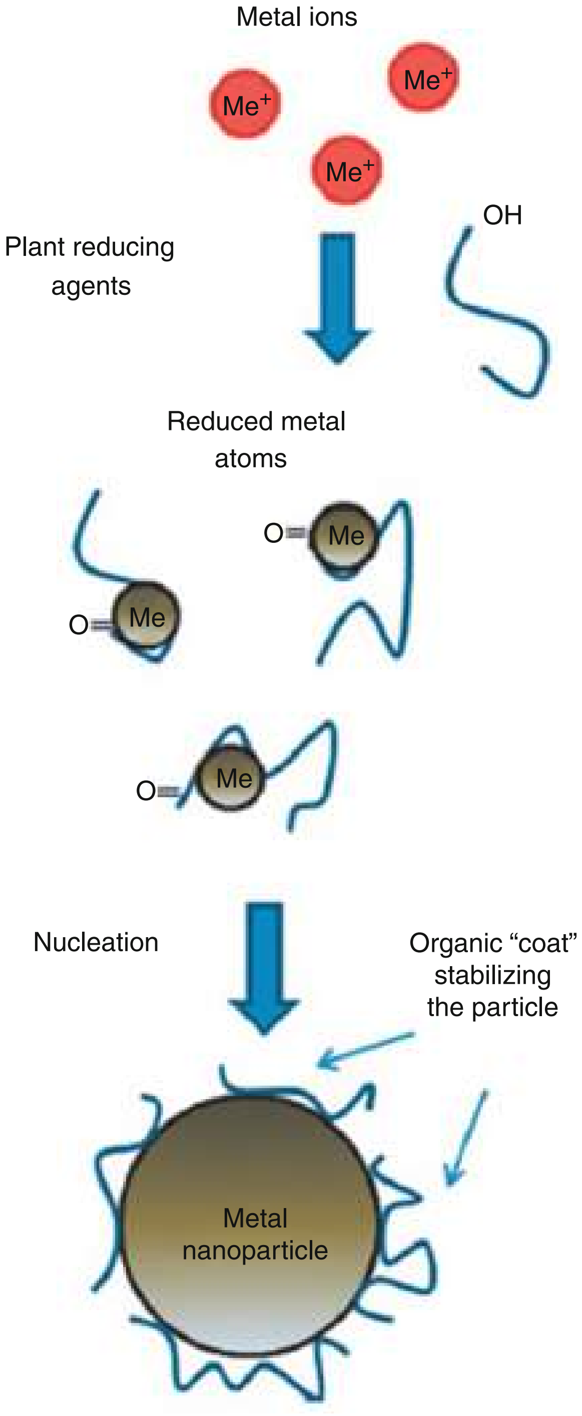

Fig. 2 An illustration of the creation of metal nanoparticles in a plant extract. The reducing metabolites and stabilizing substances bind to the metal ions, reducing them to metal atoms. The metal ion and metabolite complex that forms as a result interacts with other complexes to create a tiny metal nanoparticle. Next, the coarsening process causes distinct tiny particles to expand and merge into larger ones. Until the particles take on a stable shape and size, this process is repeated [39]. (CC BY 4.0)

recording with a recording density of up to 1 Tb/in2 if the particles are properly organized. Coprecipitation, sonochemistry, colloidal methodology, solvothermal, combustion synthesizing, hydrothermal method, microemulsion, and thermal breakdown procedures are a few of the approaches that have been reported [35]. Magnetic nanomaterials (MNs) serve as the primary purpose in the bioseparation technique in which a combination of biomolecules of interest made functioning with particular receptors leads to mixtures that are easily attracted by the strong magnetic field that is produced and generated from the pristine mix. This method is quick and easy compared to conventional techniques like centrifugation and filtration. Furthermore, this technique is used in MRI, hyperthermia, medication administration, and biological detection [36].

2.3 Metallic Nanoparticles

Metal nanoparticles are those measuring sizes (length, breadth, and thickness) ranging from 1–100 nm. Multiple liquid-phase techniques, such as biochemical diminution, solvent gel, and reversed micelle, can create metallic nanoparticles. The metal nanomaterials that are recently discovered are produced by using chemical reduction mechanisms having forms of sphere-like structures and sizes [37, 38]. This diagram depicts the various methods used to make the metallic nanoparticles shown in Fig. 2. Metal nanoparticles are extensively used due to their unique properties, such as handling many low coordination locations and offering unique electronic configurations between molecular and solid states. These variables are used for a variety of purposes, which include the magnetic division of designated cells and other biological components, the therapeutic transportation of drugs, gene sequences, and radioactive substances, radiofrequency methods for tumor hyperthermic catabolism, and contrasting drivers for magnetic resonance imaging (MRI).

3 Characterization of Synthesized Nanoparticles

The scientific investigation of a material's constituents, configurations, and chemical and physical characteristics is known as characterization. Nanoparticles are frequently recognized by their size, form, and charge on the surface using state-of-the-art microscope methods like atomic force, electron transmission, and scanning electron microscopy. The general condition of nanoparticles made of polymers, which can affect their toxicity, may be evaluated using electron microscopy technologies, which are highly beneficial. The physical durability of these nanoparticles, as well as their redispersibility and efficiency in vivo, are all influenced by the surface charge they possess.

3.1 Scanning Electron Microscope (SEM)

Scanning electron microscopy (SEM) enables direct anatomical investigation viewing. We employed electron imaging for morphological and measurement analysis;

however, these images only give limited information on the scale distribution. The approach is primarily and fully reliant on electron imaging. To do an SEM study, nanoparticles must initially be reduced to powdery. Once this has been accomplished, the nanoparticles must be deposited on an organized carrier and blanketed with a reactive metal, such as gold, utilizing a stutter coater. After that, a focused first-rate electron beam is used to conduct an inspection of the design. The surface of the ground is determined using secondary electrons. In order to prevent the polymer from being damaged, the nanocrystals need to be able to tolerate high pressure and electron beams. The effects acquired using dynamic moderate scattering are equivalent to the suggested length that was achieved through SEM [40].

3.2 Transmission Electron Microscope (TEM)

Preparing samples for transmission electron microscopes is complex and time-consuming, mainly because the specimen must be excellent for electron transmission [40]. When applied to support sheets or grids, nanoparticle dispersion is utilized. Nanomaterials are either bonded with a damaging staining agent that includes phosphorous tungstic acidic compounds or its associated products, the acetate material salt of uranium oxide, or plastic embedding so that they may better withstand the device hoover and so that their handling is simplified. This helps the nanomaterials better endure the instrument hoover. The sample can then be heated to the temperatures of liquid nitrogen after first being completely submerged in vitreous ice. The surface characteristics of a model can be reconstructed by passing a fragile specimen through an apparatus that reacts to the sample as it moves through the machine.

3.3 Particle Size Analyzer

The structure and distribution of particle sizes of developed nanoparticles are the most critical elements in characterizing them. Nanoparticles are mainly used in the transport and targeting of medications. It has been found that particle size influences the rate at which medicines are discharged. Because smaller fragments have a greater surface area, most medicines applied to them will be subjected to the nanoparticle surface. Therapy, on its counterpart, progressively spreads inside larger fragments. The drawback of the distribution of nanoparticles is that tiny particles tend to clump together when kept and transported. Consequently, nanoparticles' compact structure and maximum safety are jeopardized [41].

3.4 Dynamic Light Scattering (DLS)

Photon correlation spectroscopy (PCS), also known as dynamic light scattering, is now the technology used most frequently to determine the size of particles. DLS is often utilized to measure the diameters of Brownian nanoparticles in colloidal fluids ranging in size from nano- to submicron structures. The incoming light undergoes a Doppler effect, which causes a change in its wavelength, when a high-energy laser is used to spotlight the suspension of Brownian-moving spherical matter [42].

3.5 Atomic Force Microscopy (AFM)

AFM operates on physically scanning materials up to the submicron level with an atomic scale probe point, and it offers exceptionally high precision in particle size measurement. Samples are usually examined with either interaction or noncontact mode in accordance with their features. A topographical map is produced in contact mode by pushing the probe in opposition to the specimen's surface. The search can float above the conductive surface while the noncontact approach is used. The ability of AFM to picture nonconducting materials without any further processing is its fundamental benefit. This enables it to image biologically complex and synthesized nanoparticles and tiny structures [43]. The most exact appearance of dimension and size dispersion may be obtained using AFM, which doesn't need any form of mathematical processing [44].

3.6 Calculation of Surface Area

Particle surface area is the sum of all particle faces per unit mass. A particle's size is proportional to its inverse squared surface area. The specific surface area of a powder may be calculated using the nitrogen adsorption method. Most frequently, people utilize the Brunauer, Emmett, and Teller (BET) method to calculate the total surface area of a thing [45].

If the particles are spherical and have a limited size distribution, the particular area of the surface gives an average particle dimension in nanometers using the method below: dBET = 6000/ñs

where S denotes the specified area of the surface in m^2/g and T indicates the estimated density in g/cm^3.

In this study, the applications of nanoparticles in the production of herbal formulations and the medicinal uses of a specific drug are discussed to improve bioavailability and therapeutic effectiveness [46].

4 Use of Metabolite-Metal Nanoparticles in Therapeutics

Plant-made NPs have a wide variety of beneficial applications, including medication delivery, medicine, agriculture, biosensors, genetic engineering, the destruction of tumors, anticancer, antidiabetic, and antibacterial effects, and many others [47–56]. Previous research demonstrated that green synthesized silver NPs may be utilized for delivering pharmaceuticals and genetic engineering, as an antioxidant, antifungal, and antibacterial agent, as a sensor for optical signals, and to function as a catalyst in chemical reactions. In addition, it has been found that green synthesized AgNPs have the potential to serve as a substrate in chemical processes [58]. Researchers are working hard in biological systems because there is a growing need to find ways to make NPs that are clean, safe, and good for the environment. NPs additionally have a wide variety of applications in the field of plant research and the agriculture business. For example, the NPs use bioprocessing to turn farming and waste products into power and other valuable things with the help of using products. In 1996, the FDA approved metal-based nanoproducts, like Feridex, a liquid colloidal solution of super-paramagnetic ferrous oxide particles, to be used as a test medium for MRI (magnetic resonance imaging) [59]. Ferumoxytol, which used to be called feraheme, is also an FDA-approved drug that was made to treat iron deficiency anemia in adults. Ferumoxytol is currently being researched as a one-of-a-sort imaging agent for MRI-based cancer studies and different CVDs [59]. Nanoparticles made using green synthesis (GNPs) have secondary molecules. These secondary compounds found in GNPs might enhance these nanoparticles' bioactivity potential and help keep them in balance by acting as stabilizers or capping agents. The antioxidative qualities of silver nanoparticles (AgNPs) produced by employing three distinct polyphenols derived from plants (resveratrol, fisetin, and epigallocatechin-3-gallate) have been strongly linked to the number of secondary metabolites they contain [60]. In contrast to AgNPs made through chemical synthesis, AgNPs made through green synthesis were better at killing harmful bacteria [61]. ZnO NPs synthesized by the green method were more successful at killing bacteria, fungus, and viruses than zinc oxide NPs manufactured through the chemical route. These findings were shown by microbiological experiments that used varied amounts of organic material (Aloe plant) and by chemical means synthesized by nanoparticles made of zinc oxide (ZnO) [62]. Nickel nanoparticles (Ni NPs) were made from a root extract of *Desmodium gangeticum*. The bioactivity of nickel nanoparticles produced using green synthesis was compared to those produced through chemical synthesis. The results indicated that the green synthesized NPs exhibited more excellent antimicrobial and antioxidant effects without damaging the epithelial cell line [63]. Different bio-nanoparticles have been studied to see if they could be used to find and treat diabetes headaches caused by glycation [64]. Also, it's interesting that the anti-diabetic effects of green synthesized ZnO NPs stabilized by secondary metabolites change in streptozotocin-induced diabetic mice depending on their size [57]. Good antioxidant activity was demonstrated by gold nanoparticles (AuNPs) derived using the methanol-based extract of *Azolla microphylla*. In contrast, antibacterial activity was shown by gold nanoparticles (HNPs) derived from *Hypoxis hemerocallidea* versus *Staphylococcus aureus, Escherichia*, *Pseudomonas Aeruginosa*, and *Staphylococcus epidermidis* [65]. However, antibiotic activity was only found in AuNPs made from *Galenia africana* against *Pseudomonas aeruginosa* [66]. Figure 3 shows a summary of the different ways in which nanoparticles can be used.

Some commonly accessible mending products based on NPs have undergone a gradual but consistent development process throughout the past few years. In the year 2006, the European Science and Technology Observatory conducted a global assessment and discovered that over 150 businesses are producing therapeutic goods at the nanoscale level. This information was published in a report titled "Worldwide

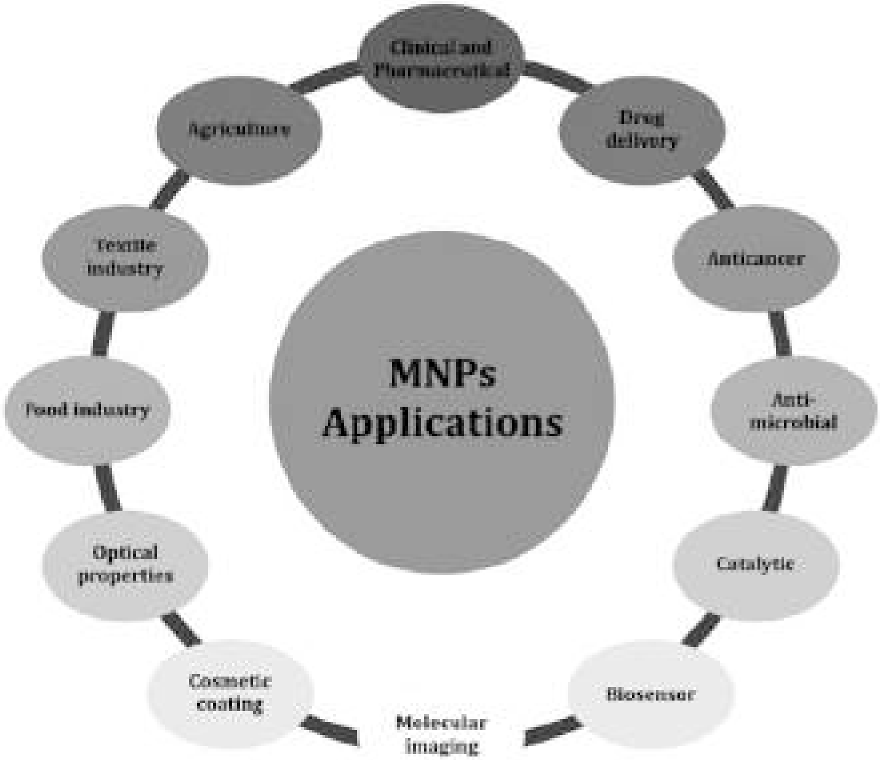

Fig. 3 Applications of metal nanoparticles [67]. (CC BY 4.0)

Review of Nanoscale Manufacturing of Healing Products." From a medical point of view, 24 mending products based on NPs have been approved so far, and they have made around $5.4 billion in sales. The best ways to take these products are in the form of polymeric pellets and liposomal drug conjugates, which account for more than 80% of the whole amount. NPs made from the breakdown products of MAPs have great packages that can help people. For example, the plant *Euphorbia hirta L.* was used to make AuNPs. Leaf extract was made into NPs, and those NPs were able to kill bacteria [68, 69]. The leaf extract of *Mimosa pudica* was used to make AuNPs on breast cancer cell lines. *Azadirachta indica L.* has phenol chemicals. Leaf extract is to blame for stabilizing AuNPs and lowering the amount of Au(III) [70]. Also, AuNPs were made using the dried leaves of *Bauhinia tomentosa*, which also showed anticancer action in a test tube [71]. So, we can say that NPs are becoming more popular to treat cancer in the modern world. In contrast to standard therapies, NPs can improve results for cancer patients and simultaneously reduce overall toxicity. Also, they have the power to get around drug resistance, which leads to better drug buildup inside cells. Nanotechnologies are now being utilized in the production of protein and DNA microarray biochips. These biochips are comparable to molecular diagnostic procedures and are associated with molecular diagnosis. Recent advances in nanotechnology for cancer treatment have opened up a wide variety of innovative administration methods for certain medications.

5 "Nanocarriers": A Demand for Nanodrug Delivery Techniques

Many herbal medication components are destroyed in the highly acidic gastric juice medium before reaching the plasma, while the liver may degrade other parts. This result shows that blood may not benefit from herbal medicines. There will be no way to establish the therapeutic action of the preparation if the elements are not delivered in the best possible quantity to the diseased site at a "minimum effective level." Because of their diminutive size and their capacity to provide a controlled dose of the medication directly to the area of action, they have become more popular; while avoiding all other obstacles like liver metabolism and the stomach's acidic pH, herbal preparations have been designated as suitable drug candidates for delivery via nanodelivery systems. The following herbal preparations have been given this designation [72]:

- Since these are wholesale medications, dose reduction is advised.
- Although it is feasible to generate acetone, chloroform, and methanol-based extracts, they may not be suitable for delivery.
- Advertised treatments for many chronic diseases lack target specificity.
- The patient's reluctance since the current formulations are less effective and require big doses.
- At present, commercialized formulations have been linked to an extensive array of additional side effects. Some of the herbal extract ingredients which are used in medications are given in Table 1.

6 New Methods for Recognizing and Characterizing Nanoscale Medicinal Plants

6.1 High-Performance Liquid Chromatography (HPLC)

The medicine industry and the industry that cleans computers often use HPLC preparation and research. The main bioactive compound of *Adhatoda vasica* is vasicine, which is tested by the HPLC method in two polyherbal drug forms – Shereeshadi Kashaya and Jastyadivati. It is observed that 18.1 mg per 100 g of vasicine in Shereeshadi Kashaya and 0.7 mg per gram of vasicine in Jastyadivati are found in both drug forms, respectively. Using an RP-18 column and an acidic mobile phase, the use of high-performance liquid chromatography (HPLC), a mixture of equal parts of *Terminalia chebula*, *Emblica officinalis*, and *Terminalia belerica* is called Triphala suspension (antioxidant-rich herbal preparation). Now, an excellent method exists to manufacture 100% plant medicines like liquorice, which are pure.

Table 1 Some herbal drug nanoparticle

Formulations	Active ingredients	Biological activity	Method of preparation
Curcuminoids solid lipid nanoparticles	Curcuminoids	Antitumor, antioxidant, antiamylodin, antiplatelet aggregation and anti-inflammatory, antimalarial	Microemulsion technique [22, 73]
Glycyrrhizic acid loaded nanoparticles	Glycyrrhizin acid	Anti-inflammatory anti-hypertensive	Rotary-evaporated film ultrasonication method [22, 74]
Nanoparticles of cuscuta chinensis	Flavonoids and lignans	Hepatoprotective and antioxidant effects	Nanosuspension method [22, 75]
Taxel-loaded nanoparticles	Taxel	Anticancer	Emulsion solvent evaporation method [22, 76]
Artemisinin nanocapsules	Artemisinin	Anticancer	Self-assembly procedure [22, 77]
CPT encapsulated nanoparticles	Camptothecin	Anticancer	Dialysis method [22, 78]
Berberine-loaded nanoparticles	Berberine	Anticancer	Ionic gelation method [22, 79]

6.2 High-Performance Thin Layer Chromatography (HPTLC)

With HPTLC, phytochemical tests and quality analyses are done on pharmaceutical medicines and formulas. Since HPTLC only uses a small amount of cellular parts, it can analyze more than one material simultaneously. HPTLC allows for precisely quantifying *Terminalia chebula* constituents such as rutin, quercetin, and gallic acids. Using the HPTLC method, the biomarkers withaferin A and the sitosterol d-glucoside had been identified in Ashwagandha at the same time. *Syzygium jambolanum's* tannin, ellagic acids, glycoside, and gallic acid were all analyzed using high-performance liquid chromatography (HPTLC) during its manufacturing for stability, longevity, accuracy, and measurement. The HPTLC method is a good way to measure diosgenin because it is quick, accurate, and cheap.

6.3 Ultra-Performance Liquid Chromatography (UPLC)

Ultra-performance liquid chromatography (UPLC) was recently used to compare traditional and powder decoctions to see the chemical responses and chemical instability.

6.4 Liquid Chromatography-Mass Spectroscopy (LC-MS)

LC-MS has become recognized as a viable choice across several drug creation phases. According to an LC-MS analysis of these medications, aminoglycosides have a low affinity for coupling to plasma proteins, a high water-soluble content, and a higher kidney excretion rate. In addition, the utilization of this methodology facilitates the recognition of amino glycosides within samples of plasma via ion chromatography using investigations with LC-MS into the pharmacokinetics of traditional Chinese medicinal medications.

6.5 Gas Chromatography-Mass Spectroscopy (GC-MS)

Using this method, it's possible to identify significant quantities of compounds found within ecological and biological processes. The GC-MS method was utilized to remember and process the chemical components used in manufacturing poly-herbal oil (Megni). Megni includes nine constituents, the majority of which are Myristica fragrances, *Mentha piperita*, *Eucalyptus globulus*, and *Gaultheria procumbens*. The GC-MS method was deployed to identify and process the chemical components. There are currently 35 flexible chemicals that have been separated and characterized.

6.6 Capillary Electrophoresis

The CE method was developed to evaluate a singular herbal remedy's description, sensitivity, and precision. There have been several published CE studies on herbal medications, but alkaloids and flavonoids, two categories of medicinal compounds, have been the subject of significant research. Additionally, the analysis period required by the CE technique was half as fast as that needed for the HPLC method, but it required more than one hundred times the amount of solvent. It has been found that it is necessary to use CE apparatus such as CE-MS, CE-NMR, and CE-diode array detection.

7 Using Nanotechnology to Create a Nanodrug Delivery System

Nanodrug delivery methods are emerging as a newest methodology for lowering the restrictions imposed by traditional drug delivery methods [80]. This is because nanodrugs have the characteristic of being extremely small. There are a variety of causes behind the rise of nanoscale drug delivery techniques including the following:

1. Infected regions can receive the most significant medication due to their exceptional size and high-loading capabilities.
2. It is best to provide the medication to the patient in tiny particles, as this can enhance the overall surface area of the drug.
3. Exhibit enhanced benefits in terms of retention and penetration.

4. Getting to the location of action of the illness does not require any additional ligand component.
5. Cause exceedingly few, if any, unintended consequences.
6. A decrease in the amount of the active ingredient in the pharmaceutical composition.

8 Recent Progress in Designing NDDS and Herbal Drug Manufacturing

Recently, the focus of specialists in the pharmaceutical industry has switched to the creation of the most effective drug delivery technique for herbal medications by using several recent scientific breakthroughs. The plant *Cuscuta chinensis* is used in ancient Chinese medicine to nourish the kidneys and the liver. Because the main components of its compositions are flavonoids and lignans, which tend to be less water soluble, taking it orally may result in inadequate assimilation. Because of this, nanoparticles used for the same purpose were manufactured commercially [22, 81]. Nanomaterials of polylactic acid used in the treatment of a lipophilic cancer-fighting herb (cucurbitacins and curcuminoids) have been the subject of recent research [22, 82] that was conducted using a technique called precipitation [22, 82]. Due to their targeted operation, appropriate bioavailability and efficacy of traditional Chinese medicine's SLNs have likewise made strides in the creation and description during the past few years. Recent studies have been undertaken on an array of nanostructured delivery systems, including SLNs, polymeric micelles, nanoparticles made of polymers, liposomes, nanoemulsions, and others [22, 83, 84]. This research focuses on using these systems to administer chemotherapy medications directly. In addition, the administration of cytotoxic drugs through the oral pathway has been hypothesized to have a significant likelihood of success. Consequently, there has been a focus on advancing oral chemotherapy for malignancy [22, 85, 86].

9 Challenges in Designing NDDS and Herbal Drug Manufacturing

At this time a wide variety of therapeutic choices are accessible to manage this fatal situation. Cancer treatment is by far the most common choice for addressing health problems. This approach may be successful to some degree; however, it does come with its fair share of drawbacks, including poor tissue access, excessive doses, unwanted cytotoxicity, drug resistance, and nonspecific targeting. Therefore, there is an immediate need to create cutting-edge technology that might aid in overcoming obstacles offered by standard cancer therapy [87].

The demand for nanoparticulate medication delivery devices is rising as nanotechnology develops quickly [88, 89]. Modern nanoparticulate dose forms can all improve a drug's bioavailability, such as polymerized nanocapsules, liposomes, nanoemulsions, and solid lipid nanoparticles. Nanoparticulate drug administration often enhances solubility and bioavailability, creates pharmacological characteristics, and disperses tissue macrophages. In contrast, traditional drug delivery lacks a drug release profile and is poorly absorbed, preventing toxicity because of prolonged exposure while hindering physical and chemical degradation [90, 91]. Characterizing the toxicological properties and efficacy of the manufactured nanoparticles is difficult [92–94]. Extensive research is still needed into the connection between the nanoparticles' forms and their functions. Plasma proteins are frequently adsorbable by nanoparticles, which interferes with the body's defense system. They might create free radicals, which might have genotoxic properties. Nanomedicines cost significantly more than conventional ones because characterizing them requires costly machinery. These nanomedicines also have a higher level of safety when compared to traditional medications, but doctors hardly ever suggest raising the level of effectiveness.

The difficulties with nanotechnology encountered during the production of natural medicines. The bioavailability of this nanoformulation has increased because of its bigger surface area and reduced particle size. However, the crucial issue is how safe and efficient it is. Overall, the intriguing promise of nanomedicines to decrease dosage frequency is a limitation of nanomedicine if a formulation enhances the pharmacokinetic characteristics. Instead, it fails to solve safety issues, resulting in toxicity in the body. High amounts of energy are required during the processing of nanoformulations like niosomes, liposomes, and polymer-based nanoparticles to solve stability-related difficulties such as coalescence and creaming [95]. Either a top-down (through pulverization or micronization) or a bottom-up approach is used to create nanoformulations (nucleation). The fundamental difficulty in expanding the formulation is controlling the growth of the particles. As a consequence, a batch-to-batch variance occurs [96].

Liposomes are an example of a nanotherapeutic substance that usually triggers an immune-mediated hypersensitive response when administered to the body. Additionally, they can be found accumulated in organs such as the liver, kidneys, and spleen [97–100]. Thrombocytopenia is a common side effect of liposomes use because they frequently interact with platelets and clotting agents like XII and XI. In order to promote their adhesion and coagulation, they also engage alongside the extracellular matrix, the lipoproteins and platelets [101, 102].

9.1 Challenges Faced to Use Nanotechnology in Herbal Medicine

The following is a list of properties of nanoparticles that are examples of factors that might impact the effective transport of herbal drugs for a particular purpose:

1. The nanoparticles' dimensions in terms of both shape and size.
2. The chemical and physical attributes of the extracts, such as their ability to remain stable and solubility in water.
3. Surface properties of the nanoparticles, including their charges, morphologies, porosity, and permeability, are considered here.

4. The level of biodegradation that has occurred.
5. The nanoparticles' biocompatibility and how they interact, in addition to any other aspects that may be pertinent.
6. Toxicity.
7. The amount of drug packed into nanoparticles and the effectiveness of encapsulation.
8. The release profile of the active component from the product, which includes information such as the component's kind (immediate, controlled, or focused release), discharge type (zero-order or first-order release), and discharge procedure (dissolution, diffusion, matrix system, etc.).
9. Antigenicity and other things.

Medications with poor solubility in water have traditionally been challenging for pharmaceutical specialists to formulate [103]. There is a substantial problem with the inability of therapeutic herbal extracts or their phytoconstituents to dissolve easily in water. Micronization, cosolvent solubilization, surfactant dispersion, and precipitation techniques are some of the standard procedures adopted in the pharmaceutical sector to improve the water solubility of medications that generally have poor water solubility [104]. On the contrary, it was seen that these approaches are ineffective when used in medicines that are not soluble in organic as well as water-based solvents.

9.2 Health Implications of Nanoparticles

It is essential to recognize the risks associated with using nanopharmaceuticals [105], despite the fact that there may be a wide variety of probable applications of nanopharmaceuticals in dispensing medicines for the diagnosis and treatment of various illnesses. There is a possibility that nanomaterials will enter the human body via several routes, including the epidermis, the gastrointestinal tract, and the lungs [106]. Nanoscale particles that enter the body through the lungs have the ability to quickly cross the blood-brain barriers (BBB) and reach crucial organs. This is because of the BBB's porous nature.

9.3 Challenges in Nanoformulation and Characterization

The size of a particle can significantly affect the pharmacokinetics (PK), biodistribution (BD), and safety of pharmaceuticals. Particulate size and its variation are some of nanoparticle-based medications' widely recognized distinguishing features. Small nanoparticles less than 20–30 nm in size are rapidly excreted by the kidneys following administration. In contrast, fragments 200 nm or bigger have a better absorption by the mononuclear phagocyte system, that is further known as the reticuloendothelial system (RES), which consists of living cells in the spleen, bone marrow, and liver [107]. The liver rapidly eliminates the particles within 200–400 nanometers, while nanomaterials within 150–300 nanometers in size are found predominantly in the spleen and liver [108, 109]. Consequently, particle size optimization is a crucial phase in manufacturing an efficacious nanoherbal composition. Nanoparticle behaviors and relationships with proteins and organelles are also greatly affected by surface characteristics [110]. Many surface attributes, including charge, hydrophobicity, and functional structures, can significantly influence nanomaterials' survivability over the long term and the opsonization process [111, 112]. With respect to traditional small molecules, the dimensions, morphologies, and physical and chemical attributes of nanoparticles may affect the pharmacokinetics (PK) and biodistribution of the active ingredients within them. Consequently, developing herbal medicines based on nanoparticles faces challenges with excellent pharmacological resistance. It is feasible to determine the detrimental effects of nanoparticles by quantifying the size, zeta capacity (surface charge), index of polydispersity, and solubility [113]. For instance, inhaling nanostructures smaller than 100 nm may result in oxidative stress and pulmonary inflammation [114]. Unstable nanomaterials possess the potential to form large aggregates that can become confined in the capillary bed of a patient's airways and cause significant problems. There is a correlation between the immunogenicity of nanomaterials and their size, surface properties, hydrophobicity, solubility, and charge. Nanomaterials could develop antigenic properties, become opsonized by plasma protein molecules, and are recognized as foreign components, triggering complement and activating rapid phagocytosis in macrophages and clearance if these characteristics are not effectively managed.

10 Past Studies and Future Prospective

Natural product and medicinal herb research has been conducted worldwide. A great number of research institutions are now working on developing herbal treatments for use in drug delivery systems at both the primary and clinical trial levels. The only requirement is to develop improved methods for administering these drugs to the appropriate sites and throughout the body in amounts that have no impact on the treatment options that are now accessible. It would be ideal to have a drug that not only lessens the severity of side effects like poisoning and allergic reactions but also makes the patient more resilient on the inside. This would be the ideal situation. Future research groups may be captivated by the idea of using botanical nanoparticles to transport anticancer medications, and they may produce noteworthy results.

Through the inclusion of "herbal medicine" in nanocarriers, the possibilities for healing many kinds of chronic illnesses and providing medical advantages will increase. Numerous successful examples supported by concrete evidence point to the right way of nanoresearch. Herbal remedies are exceptionally high in antioxidants and components which can be incorporated into foods for specific purposes [115]. This type of collaborative research between traditional "herbal treatments" alongside more modern techniques of the present medication delivery system, i.e. "nanotechnology," has created the pharmaceutical drugs that will enhance the wellness of people shortly. It is predicted that the advantageous and important applicability of natural items and herbal treatments used with the nanocarrier would raise the relevance of the present-day technique for the delivery of drugs [22].

Herbal remedies which are nanosized particles are able to enhance biological function and resolve problems with herbal medicines alone. The two new challenges in the development of nanotechnology-based drug delivery methods are the potential to obtain systems with multiple functions that satisfy distinct biological and therapeutic requirements and the feasibility of growing procedures that quickly develop novel approaches for therapy to the market. The study of the possible toxicological consequences of nanoparticles, known as nanotoxicology, has recently emerged as a new branch of toxicology. In previous decades, the beneficial effects of medical advances and their impact on patients' quality lifestyles were taken into account. The expenses related to medical treatment must now be considered. The objective of nanotherapeutic gadgets, which have more complex structures and are more expensive than conventional alternatives, is to decrease the total expense of healthcare [116].

Increased nanotherapeutic efficacy, shortened hospital stays, lower personal healthcare expenditures, and the successful management of costly primary maladies are likely contributors to this decline in costs associated with healthcare. The pharma regulation environment, healthcare policy, demographics, and general economic climate significantly impact the market for nanomedicine-related pharmaceuticals. Companies specializing in nanomedicine used specific approaches to surmount the challenges that arise in this fiercely competitive industry. BCC [117] found that the EU healthcare systems will be exposed to an increasing number of novel nanomedicine products due to the increased interest in and investment in nanotherapeutics. Incorporating nanotherapeutic treatments in country medication reimbursement policies will significantly impact the accessibility of these therapies across all healthcare systems. It is important to exercise caution when introducing nanoparticles into an ecosystem vulnerable to their effects, as the surroundings are already laden with nanoparticles of particulate matter. Investigating the targeting efficacy of nanomaterials and meeting global toxicological and biocompatibility standards are two additional new issues. Prospective use of nanopharma may alter human health in unimaginable ways, therefore evaluating their benefits and drawbacks has become essential.

11 Conclusion

The multidisciplinary development of nanotechnology is hastening the creation of the nearly impossibly compact gadget. Herbal extracts for medicinal purposes have already been recognized for having fewer negative impacts and are commercially accepted globally. When it comes to pharmaceuticals, nanotechnology offers a wide range of potential uses because it may enhance drug bioavailability and usage by decreasing drug size. National laws that govern the evaluation of medicinal plants' safety, quality, and effectiveness, alongside WHO attempts to support the development of model standards in these fields, have helped to strengthen recognition of medicinal plants' position in healthcare. Despite several breakthroughs, providing therapeutically effective drugs in this industry continues to face numerous challenges. One of the most significant obstacles in transforming these technologies into therapies is testing modern techniques to control how nanoparticles interact with biological constituents. Using nanoparticles and novel nanomedicines in conjunction with herbal treatments is less widespread since there is still a need for evidence of their safety and hazardous danger. However, if clinical validation information is obtained methodically, it can readily rub shoulders with contemporary medicine and lead to an entirely new segment of therapy in the medical world.

Eco-metabolomic Studies of Medicinal Plants and Herbal Medicine

54

Hunny Waswani, Mrinalini Prasad, and Rajiv Ranjan

Contents

Abstract

Ecometabolomics is becoming recognized as a valuable approach in ecological research, owing to recent advancements in technology, such as HNMR spectrometers, and bioinformatic progress. These improvements have facilitated the inclusive analysis of the metabolome, encompassing the entirety of metabolites, and their dynamic alterations in response to ecological perturbations. This quickly

evolving technological platform offers a thorough qualitative and quantitative analysis of a particular metabolite set or the entire metabolite composition of a part. As a result of this technology, drugs are being discovered from natural plant resources, medicinal plant quality is being controlled, and new lead compounds are being discovered in recent years. From the perspective of small-molecule metabolism, metabolomics can be a terrific way to understand and enhance herbal remedies. By using a metabolic approach, development of novel pharmaceuticals, and encouraging the research. The scientific obstacles surrounding herbal remedies can be surmounted. In this chapter, we discussed the popular analytical methods used in metabolomic investigation and highlighted the relevance of eco-metabolomics in addressing several metabolites.

IMS	Ion mobility-mass spectrometry
NMR	Nuclear magnetic resonance
WHO	World Health Organization

1 Introduction

Natural habitats and the environment have been the most preferable sources since the beginning of human life. Food, energy, and therapeutics can all be found within local habitats and in nature. The current annual global pharmaceutical industry is worth roughly US$1.1 trillion. A third of these medications (about 35%) are made from natural ingredients, including substances derived from plants (about 25%), microorganisms (about 13%), and mammals (about 3%) [1]. Additionally, natural goods or their derivatives make up about 30% of the top-selling medications worldwide [2]. Furthermore, of the 1562 new medications that the US FDA approved between 1981 and 2014, 141 (9.1%) were botanical medicines comprising plants (defined mixtures), 64 (4%) were natural products that had not been altered, 61 (4%) were artificial medications that had a natural product pharmacophore, and 320 (21%) were natural product derivatives [1, 2].

The expected number of metabolites produced by plants in the plant kingdom ranges from 200,000 to 1,000,000 [3]. Numerous developed to withstand environmental challenges, defend against predatory animals, and function as chemical attractants [4]. Plants with these metabolites have been utilized for generations to treat and prevent illness. The bioactivity of the majority of these products against various malignant tumors and infectious illnesses has been established. Additionally, it is predicted that the global market for these natural goods is worth US$60 billion annually [5]. According to estimates from the WHO, medicinal plants are the main source of medication for about 80% of the world's population. Pharmacologically active molecules, medical agents, and drug research leads have increasingly been derived from plant natural products in recent years [6]. Medicinal plant-based metabolomics research is crucial because plants produce various primary and secondary compounds in large amount, some of which might be useful therapeutically. Approximately 200,000 secondary chemicals derived from plants have been subjected to scientific investigation [7]. For instance, *Arabidopsis thaliana* has produced 5000 secondary metabolites, while 1500 and 2500, respectively, have been derived from microorganisms and mammals. For the investigation of a variety of properties, such as metabolite profiling in plants, various genomics-based "phytochemical arrays" (proteome, transcriptome, genome, and metabolome) have been developed [8]. There have been reports of potential anticancer action in plant secondary metabolites such as camptothecinpaclitaxel (taxol) and podophyllo toxins among others [9]. As a result, alternate methods for finding new chemical entities (NCEs) for medication advancement are being explored, such as medicinal plants or natural products. From *Salix alba*, aspirin which is a semi-derivative chemical, has been utilized for many years [10] as a miracle medication to treat issues like pain. The best techniques for finding/isolating novel compounds, like morphine from opium, etc., are through ethnic applications of plants as traditional remedies (in the form of crude or extract). This was a technique for finding drugs from natural materials at the beginning of the nineteenth century. Because of their rarity in plants and consequently weak therapeutic action, a few plants secondary metabolites (single compounds) are frequently only weakly identified during drug analysis. However, since herbs and their formulations contain a variety of constituents, the biological activities can be generated synergistically. Metabolomics can be a useful tool in this situation to comprehend the phytochemical underpinnings of such medically active phytoconstituents [11]. Through various cutting-edge hyphenated technologies, in the realm of herbal medicine, metabolomic fingerprinting can be very beneficial for medication development, gene-function research, systems biology, and a variety of diagnostic methods. Targeting metabolomics is the study of a cluster of identified metabolites, and it typically combines NMR-MS techniques, which are employed in these kinds of analyses [12]. This aimed metabolomics technique determines the comparative concentration of around 200 predefined metabolites in a trial.

Through GC-MS and LC-MS analysis, the undefined or unknown plant metabolites may be found in a "untargeted" metabolomics investigation. This can be very beneficial for categorizing and identifying metabolites as well as for assessing herbal medicine [13]. Numerous areas of application can benefit from metabolic studies. Metabolite fingerprinting is a versatile analytical technique that encompasses various applications, such as the quantitative and qualitative assessment of specific molecules, the identification of chemical groups, the quantification of all metabolites, and the quick study of metabolites [14]. According to recent research, herbal remedies may be helpful in the treatment of a number of illnesses. The complexity of their chemical makeup now hinders the development of herbal pharmaceuticals, which use bioactive compounds with uncertain modes of action, unknown therapeutic targets, non-specific properties for drug metabolism, etc. To overcome these problems, metabolomics can be a useful method for learning about and bettering the small-molecule metabolism of herbal medicines, also with a metabolic perspective, metabolomics could accelerate the discovery and development of new pharmaceuticals by resolving scientific issues with natural therapies. Recently, there has been a significant utilization of MS-based metabolomics for the purpose of examining the in vitro and in vivo constituents of herbal extracts. In this study, we emphasize the importance of metabolomics and metabolism based on mass spectrometry for addressing the complication of herbal medicines in systems. Research on phytomedicine is now receiving special attention as a result of this investigation. It can be extremely helpful in changing the way that drugs are discovered and developed using natural materials.

2 Eco Metabolomics

The growing use of new technological advancements, such as contemporary GC-MSand HNMR spectrometers coupled with bioinformatic advancements, has raised understanding of Eco metabolomics, a discipline that investigates the metabolome, encompassing the complete assemblage of metabolites, and its dynamic alterations in reaction to shifts in the environment. For metabolomic approaches used in ecological investigations, we utilize nomenclature based on that of [15, 16] but simplified. Metabolomic profiling is the designated study type where the aim is to quantitatively analyze a collection of metabolites belonging to specific metabolic paths or distinct metabolite categories (e.g., polar, semi-polar, and non-polar), with as well as without their identification. The term "partial ecometabolomic studies (PEM)" is used to describe the investigation of an organism's response to ecological changes through the detection of specific metabolites or its group. This is achieved by employing quantitative and qualitative analytical procedures such as NMR or GC-MS. PEM refers to metabolomic profiling investigations conducted in the context of eco-physiological or ecological research endeavors, with the objective of unravelling a particular comprehensive pathway or the interconnections between many pathways. Hence, target studies that use many target techniques, like HPLC, and are concentrated on the analysis of a small number of metabolites are not regarded as ecometabolomic investigations.

Partial ecometabolomic studies are what we propose to name them. It is frequently sufficient to quickly categorize samples in accordance with their origin or their eco-physiological or ecological relevance when it is not necessary or possible to identify every metabolite. Metabolic fingerprinting is the term used for this procedure, which we now propose to refer to as exometabolic fingerprinting in an ecological setting. Through a suitable interpretation, the aforementioned "holistic" approach facilitates the objective investigation and analysis of molecular biochemistry samples, hence enabling the research of plants' responses to alterations in their surroundings [17, 18].

Analytical methods that allow for the measurement and identification of a wide range of metabolites are essential for determining and quantifying the maximum number of metabolites within a particular biological system. The term "metabolomics" refers to a method that reveals as much as possible about the metabolome of the biological system being studied. The term "ecometabolomics" is suggested to be used in reference to the investigation of an organism's comprehensive metabolomic response to alterations in the environment within an ecological framework. In actuality, the latter method ecometabolomics is the most suitable for understanding an organism's full reaction to environmental changes.

3 Metbolomics an Important Tool

Metabolomics is an emerging discipline within post-genomic biological research that is dedicated to investigating the characteristics and functions of tiny compounds, typically weighing less than 1000 Daltons, which are synthesized or utilized within biological systems. Metabolomics provides a comprehensive methodology for comprehending the molecular alterations that transpire across a complete body by examining the impacts of these molecules on biological or natural systems. This discipline gives significant insights into the influence of diverse elements on biological systems and presents a comprehensive viewpoint on the interaction between molecules and biological processes [19, 20]. Because metabolites change more quickly than genetic materials, they are thought to be a better indicator of ongoing physiological events than phenotypes [21]. In essence, the scientific community has used metabolomics frequently and regards it as a method for identifying biomarkers [22, 23], disease diagnosis [24, 25], novel drug discovery [26], drug mechanism study [27, 28], drug safety assessment [29], and toxicology evaluation [29], because it offers extremely dependable and repeatable findings. The metabolome is the entire set of metabolic molecules, varies from the genome, transcriptome, and proteome in some ways. Metabolites are more diverse in terms of their physicochemical nature than DNA or proteins [15, 30, 31]. The present difficulties in the study of plant metabolites are their heterogeneity and complexity considering that only one-fourth of the estimated 200,000 metabolites in plants have been fully characterized [15, 32, 33]. The metabolome reflects the intricate connections that occur among the genome, transcriptome, proteome, interactome, and interaction networks [34]. Consequently, metabolomes not only supply the cell with the metabolic components it needs, but also serve as a diagnostic tool [35]. The metabolome serves as the culmination of interactions between the environment and biological system, whereas the genome specifies indirectly what might occur [36]. Furthermore, the use of metabolomics data analysis does not vary on the presence of organism-specific genome data, unlike proteomics data analysis, genomics, and transcriptomics, which necessitate such information [37]. Regardless of the creature that produces them, this special characteristic comes from the same molecular object as metabolites [38].

4 Mass Spectrometry Techniques Applied to Metabolomics

Despite NMR and MS being the most frequently used analytical methods in metabolomics, MS is usually chosen because of its unparalleled structural specificity, high resolution, and sensitivity. In practical applications, the pre-separation process involves the integration of IMS, Gas Chromatography (GC), Liquid Chromatography (LC), or other methodologies with Mass Spectrometry (MS) [39]. The advancement of MS-imaging (MSI) tools has contributed to an enhanced comprehension of metabolomics by broadening our knowledge of the spatial allocation of metabolites.

4.1 Gas Chromatography-Mass Spectrometry

In the early 1970s, Devaux conducted pioneering research on metabolite profiling, employing GC-MS to investigate various constituents of steroids as well as urine drug metabolites [40]. GC-MS is a cost-effective as well as reproducible analytical technology that offers a high peak capacity for MS analysis. It is particularly well-suited for detecting thermo-stable volatile compounds or their derivatives. However, it necessitates intricate and time-consuming sample preparation, which can potentially alter the structure of the analytes during the process. Despite its shortcomings, GC-MS is nevertheless often employed in metabolomics due to the abundance of commercial and public libraries for chemical identification [41]. Using GC-MS, researchers examined the medicinal benefits of Jieduquyuziyin, a traditional Chinese medicine formulation containing Rehmanniae Radix, Trionycis Carapax, and Artemisiae annuae herba (the dried aboveground portions of *Artemisia annua* L.). Multivariate statistics revealed 11 metabolites that were linked to the metabolism of amino acids and energy, including malic acid, citric acid, hippuric acid, etc. The disruption of these networks may prevent the body's regular physiological processes and hasten the onset of systemic lupus erythematosus. For preferred therapeutic outcome, the concentrations of metabolites seen after administering the Jieduquyuziyin prescription were found to be similar to those observed in the control group. The findings of this analysis provide clarification regarding the therapeutic effects of the Jieduquyuziyin prescription on systemic lupus erythematosus, as observed by the analysis of urinary metabolomics using GC-MS. A significant male infertility condition in traditional Chinese medicine is called KYDS. In this study, a metabolomics approach utilizing GC-MS was created to investigate the modernization of KYDS (Kampo-Yonin-to-Dokudami-San) for the treatment of male infertility. A total of 67 infertile males diagnosed with KYDS and 55 healthy controls were recruited as participants for this research endeavor. A total of 37 potential biomarkers were identified across six metabolic pathways. Among these indications, ten were found to effectively differentiate infertile individuals with KYDS from healthy individuals, hence offering valuable insights into the underlying process [42].

4.2 Liquid Chromatography-Mass Spectrometry

Traditional medicine recognizes several treatments for the dampness-heat jaundice syndrome, including Artemisia capillaris Thunb., Rhei Radix et Rhizoma, and Gardeniae Fructus (the dried mature seeds of *Gardenia jasminoides* Ellis). In a study conducted by Sun [43], the therapeutic mechanism of YCHT was examined. The researcher employed UPLC-MS-based technology to analyze metabolite alterations that occurred during the treatment. As a result, an integrated biological interpretation was developed. Consequently, the association between the syndrome of dampness-heat jaundice and a total of 22 biomarkers and 8 metabolic pathways was established. The development of the biomarker-protein interaction network was also undertaken in order to forecast potential targets. In their study, Zhu [44] employed UPLC-Q-TOF MS to exhaustively elucidate the mechanism as well as targets of Huanglian Jiedu Decoction in the context of cerebral ischemia. This decoction consists of Coptidis Rhizoma, Scutellariae Radix, Phellodendri Amurensis, Gardeniae Fructus, and Cortex. A total of 19 biomarkers associated with ten metabolic pathways were identified in the experimental groups that underwent therapy with Huanglian Jiedu Decoction, in comparison to the control group, as well as the groups with cerebral artery blockage and normal conditions. The study of metabolomics and pathophysiology has established that Huanglian Jiedu Decoction exerts its pharmacological effect on cerebral artery occlusion through the maintenance of cholinergic neuron function, modulation of metabolic stress, and regulation of the glutamate/gamma-aminobutyric acid (GABA)-glutamine cycle. These studies were able to effectively elucidate the targets and mechanisms of drug action using UPLC-MS-based metabolomics.

4.3 Capillary Electrophoresis-Mass Spectrometry

Charged analytes can be quickly and precisely separated via CE using minimal injection volumes. It is a potent analytical technique that, when combined with MS, allows for molecular characterization based on fragmentation and provides (precise) mass information. Highly charged metabolites and nucleotides are among the kinds of metabolites that the platform can easily capture, despite being incredibly sensitive and capable of doing so. The separation efficiency observed in CE is generally superior by a factor of ten compared to that achieved in traditional high-performance liquid chromatography [45]. Whereas the performance of LC is typically constrained, CE is applicable for the split of polar drugs (charged) or metabolites [46]. For the same sample, different settings can be swapped out to expand coverage. The productivity of the separation procedure in CE is completely influenced by the magnitude of the applied electric field, which effectively facilitates heat dissipation. The biggest obstacle to its widespread adoption is its inherent lack of consistency. Though there aren't many instances where CE-MS is used in metabolomics, those who are adept at using it can achieve separation efficiencies that are on level with or even superior to GC-MS and LC-MS results. In the study conducted by Kimura [47], plasma obtained from a prospective cohort of 112 patients was utilized for the purpose of performing a CE-MS metabolic profiling of end-stage kidney disease. There were 218 metabolites found in total, and 16 of them have predictive readings for end-stage kidney disease, which is a condition that is associated with a high risk. In addition, 73 of the metabolites had a substantial relationship to the estimated glomerular filtration rate. The assessment of metabolites can potentially aid in the management of chronic renal disease by assessing the probability of its progression to end-stage kidney disease.

4.4 Ion Mobility-Mass Spectrometry

IMS is an electrophoretic method that operates in a gas phase, enables rapid segregation of ions according to their size, charge state, and structure [48]. The utilization of collisional cross-section (CCS) values, which are a unique molecular physicochemical attribute that represents the dimension and structure of ions, has the ability to facilitate the process of identification of metabolites [49]. Recently, an improved method of metabolite analysis has developed that combines IMS and MS. This technique improves the identification and coverage depth of metabolomics by providing millisecond structural resolution and multi-dimensional in addition to mass information [49]. The utilization of IMS has facilitated a novel approach in the discipline of metabolomics, allowing for the acquisition of multi-dimensional molecular data suitable for both semi-targeted and untargeted research purposes. Lipids constitute the principal constituents of cellular membranes and play a critical role in the metabolic processes essential for sustaining life. The precise determination of their natural functions has been impeded by the prevalence of isomers and the absence of a proficient analytical apparatus. The application of IMS was extensively investigated for the purpose of distinguishing between lipid isomers. The success rate in differentiating the four primary categories of glycero- and phospholipids was found to be 75%. These lipids can be distinguished based on variations in sn, cis/trans configurations, chain length, and the position of double bond. The results of this study showcased the efficacy of IMS as an effective implement for conducting lipidomic investigations [50].

4.5 Mass Spectrometry Imaging

The first step in the investigation of biological tissues using LC-MS-based metabolomics involves the homogenization of samples to extract metabolites [51]. The method employed in this study involved combining the metabolites from all cells within the specimen to evaluate the overall influence on the tissue as a whole. However, it should be noted that this technique does not account for the spatial characteristics of the tissue. The utilization of MSI technology in the context of identifying metabolites in situ holds significant promise as it allows for the visualization and characterization of metabolite distribution and changes. The most advanced imaging method used today is MALDI MSI. The sectioned tissues are subsequently transferred onto a MALDI plate, where they are subjected to matrix spraying, laser rastering, and subsequent collection of their MS spectra, peak intensities can be transformed and then translated into two-dimensional images, allowing for the natural visualization of metabolite changes. Other ion sources besides MALDI can be used for MSI, including secondary IMS, laser ablation electrospray ionization, and desorption electrospray ionization. Medical research, microbiology, and natural product chemistry are just a few of the life sciences fields where MSI methods have created new opportunities [52]. Sarabia [53] developed a high-resolution matrix-assisted laser ionization MSI technology to investigate the impact of salinity stress on the structural distribution of metabolites in the barley seedlings roots. The researchers conducted a comparative analysis of metabolites prior to and during exposure to salt-induced stress. They successfully identified, visualized, and distinguished several chemicals in meticulous detail throughout longitudinal sections of the root. The levels of Phosphatidylcholine (PC [54: n]) exhibited a general decrease in salt-treated roots, indicating a reaction to the stress induced by high salinity. To investigate the spatial dynamics of plant growth and metabolites, researchers employed a novel methodology to grab a deeper understanding of the spatial metabolomics occurring in the maturation zone and elongation region during root development following an exposure to salt-induced stress. This approach facilitated the elucidation of underlying mechanisms involved in plant responses.

5 The Methabolomics Approaches Used in Herbal Medicine Research

The fundamental method and consistent detection for the precise identification of unidentified metabolites is NMR-based metabolomics. But compared to MS, this technology is less sensitive. Currently, MS is the most popular tool in plant metabolomics [55]. The first technique in plant metabolomics discipline is the utilization of gas chromatography coupled with electron impact and time-of-flight mass spectrometry (GC-TOF-MS), which is widely implemented [56]. GC-TOF-MS enables the achievement of high reproducibility in the separation and fragmentation patterns of lipophilic compounds and non-volatile primary metabolism metabolites [57]. CE-MS offers the most optimal means of detecting and separating a variety of polar primary metabolites. Contrary to GC-TOF-MS, it is a technique that is infrequently employed [58]. The most effective approach for the characterization and identification of semi-polar metabolites involves the utilization of LC-MS coupled with atmospheric ionization techniques, such as chemical ionization, atmospheric pressure, and electrospray ionization. In general, LC-MS is commonly employed for the identification of many plant secondary metabolites, including but not limited to alkaloids, saponins, flavonoids, phenolic acids, polyamines, and their derivatives [59, 60]. These metabolites can be immediately analyzed without any derivatization because they are typically extracted with hydroalcoholic solutions [61]. Direct flow injection mass spectrometry (DFI-MS) enables the direct assessment of metabolic signatures without the need for earlier separation. Nevertheless, the utilization of this direct injection technique may give rise to complications pertaining to ion suppression and the development of substantial adducts. Additionally, DFI-MS is unable to distinguish between multiple molecule isomers. Therefore, a separation method must be used in plant metabolomics research using MS-based platforms. In general, vegetation contains a lot of isomeric compounds. Such isomeric substances can be detected using LC in conjunction with MS. Additionally, in addition to allowing, it also offers helpful details about the metabolite's structure that can be collected online [62]. A single crude plant sample can contain hundreds of metabolites when LC and high-resolution MS are combined. The LC-MS technique, known for its rapid advancements in data collecting and processing, is considered the most advantageous approach for metabolite identification. Among the advanced techniques employed in plant metabolomics, LC-NMR and LC-NMR-MS are notable for their sophisticated identification capabilities [63–66].

6 The Analysis of Untargeted Metabolites in Medical Plants Based on LC-MS

Polar sugars and different lipids are among the thermolabile and non-volatile substances that can be analyzed using LC-MS. Due to its ubiquitous adaptability to the majority of compounds, LC has been the most effective method for studying herbal medicines. Capillary LC, monolithic column (single piece column) UPLC, and LC were created to increase segregation effectiveness; this approach offers a high level of precision and provides an untargeted analysis. As a result, it can be used to analyze a variety of plant compounds. Untargeted metabolomics investigates the entire plant metabolome without favoring any particular compound. Untargeted metabolomics is the best method for thorough qualitative and quantitative study of herbal medications.

6.1 The Typical Workflow for Untargeted Metabolomics Using LC-MS Studies

The process of untargeted metabolomics investigations utilizing LC-MS typically involves many fundamental phases. The preliminary stage of the research process involves the preparation of the experimental design, which is subsequently succeeded by the groundwork of the sample and the collecting of data. The efficacy of these steps is contingent upon the specific aim and purpose of the research inquiry [67]. Sample preparation is a very important stage, and it can be affected by a number of sample integrity factors [68]. The choice of extraction technique and solvents employed significantly influence both the quantity and diversity of metabolites obtained. For the extraction of metabolites, a singular solvent solution is typically employed. However, it is also possible to extract a variety of metabolites from the plant sample using a mix of solvents [69, 70]. The advancements in automatic data processing means such as XCMS, Metalign, and MZmine have facilitated the analysis of complex untargeted metabolomics data and the abstraction of crucial information from raw chromatographic data. This approach facilitates and empowers the analysis of vast quantities of untargeted metabolomics data [71, 72]. Once the procedure of data processing has been concluded, it becomes imperative to analyze the acquired data in alignment with the research's purpose and objective, employing the suitable methodology. Identification and measurement of the entire plant metabolome is the primary goal of untargeted metabolomics (both known and unknown metabolites). With untargeted metabolomics, it is difficult to use simple statistical analysis or other traditional statistical techniques. As a result, this technique uses multivariate statistical methods to analyze huge data sets of unidentified metabolites. The application of untargeted metabolomics also enables the identification of synergistic effects that may not be discernible at the individual level. The issue under consideration can be effectively addressed by applying multivariate statistical approaches that are grounded in the concept of projections. In this approach, it is possible to integrate the elements under research with the latent variable. Principal component analysis (PCA) is generally utilized in the examination of exploratory data. In contrast, projection to latent structures discriminant analysis (PLS-DA) and orthogonal projection to latent structures discriminant analysis (OPLS-DA) are widely recognized as highly successful statistical methodologies for extracting concealed information that enables the categorization and characterization of system behavior [73]. The two primary processes for transforming secondary metabolites in plants are esterification and glycosylation. The pharmacological effects of these various secondary compounds are produced. However, it is very tough to perfectly determine the metabolites in untargeted metabolomics. The coverage of metabolites in existing databases such as HMDB, MASSBANK, MS2T, METLIN, Campus Chemical Instrument Centre, and Birmingham Metabolite Library is inadequate due to the extensive diversity of plant metabolites [74, 75]. The fragmentation and mass pattern of plant metabolites can be accurately determined with the help of tandem mass spectrometry, which simplifies structural analysis.

7 The Analysis of Untargeted Metabolites in Medical Plants Based on NMR Analysis

The integration of contemporary multivariate statistical analysis techniques, in conjunction with the latest breakthroughs in analytical chemistry focused on the identification and characterization of tiny molecule compounds using high-field NMR, has facilitated the development of very efficient methodologies for doing extensive analysis of data derived from metabolomics investigations. NMR procedures exhibit notable attributes such as expeditiousness, dependability, and the ability to produce consistent results. One advantage of this method is its universality in detecting all NMR active substances, distinguishing it from mass spectrometry-based techniques. This is attributed to the proportional relationship between signal strength of protons and metabolite quantity, enabling direct comparison of compound concentrations. In the subject of plant metabolomics, the utilization of solid phase extraction in combination with LC and NMR, or HPLC-NMR has quickly increased.

7.1 A Workflow for Untargeted Metabolomics Studies Utilizing NMR

The fundamental procedures involved in untargeted metabolomics investigations utilizing NMR are analogous to those employed in studies utilizing LC-MS. In these studies, the step of sample collection and extraction is essential. Deuterated solvents are typically used as the extraction fluid. For the NMR investigation, combinations of KH_2 PO_4 and D_2O and CD_3OD are employed to extract the full metabolome [69]. The development of data processing technologies like as SIMCA and ACD Labs has facilitated untargeted metabolomics investigations by efficiently analyzing several variables and extracting significant information from NMR spectroscopic data. In the untargeted metabolomics approach, multivariate statistical methods will be employed to analyze a diverse range of unidentified plant metabolites using the data obtained from NMR. With the use of this technology, multivariate statistical methods for LC-MS-based metabolomics can be applied [76]. Several variables, including concentration, pH, ionic condition, temperature, can affect the sensitivity of NMR parameters [77]. Consequently, the detection of metabolites is the most difficult. In order to enhance the discernment of plant metabolites, it is imperative that the NMR spectra be obtained under identical conditions as those employed during their acquisition for the database. Multiple multidimensional nuclear magnetic resonance (NMR) tests must be performed to validate the identified metabolites within a cohort of similar samples, including TOCSY, HMQC, HMBC, HSQC, or a combination of HSQC-TOCSY/HMQC [78]. Derivatizing agents, which are chemically selective probes, can be employed for the purpose of measuring functional groups. These agents have the ability to precisely target aldehydes, ketones, thiols, and carboxylates. The chosen metabolites containing specific functional groups can be identified by strategically including isotopes such as 15N or 13C at specific locations inside the chemically selective probe, utilizing the isotope-editing capability of Nuclear Magnetic Resonance (NMR) [79, 80]. Metabolites fingerprinting has been done to analyze the Indian medicinal plants metabolites which are listed in Table 1.

Table 1 Metabolite fingerprinting of traditional Indian medicines: the table showing Indian medicinal plants which undergo various metabolomics approaches

Indian medicinal plant	Metabolomics analysis approach	Metabolites analyzed	References
Commiphora wightii	GC–MS, NMR, HPLC	n-Methylpyrrolidone; GuggulsteroneZ,E; Isoeugenol; α-tocopherol; β-Caryophyllene; β-Myrcene; δ-Cadiene; D-limonene; Quinic acid; β-Elemene; Guaiacol; α-Caryophyllene; Verticiol; transFarnesol; Prostaglandin F2; myo-inositol; Protocatechuic; Cinnamic acids: Gallic acid.	[81]
Psoralea corylifolia	HPLC/UV–MS GC/MS	Neophytadiene; Psoralene; Daidzein; Stearic acid; Myristic acid; 1,2-Benzenedicarboxylic acid; Phytol; Caryophyllene oxide; 2Furancarboxaldehyde,5-(hydroxymethyl); Linoleic acid; Bakuchiol; Phytol; Palmitic acid; 2,6Dimethoxyphenol; 2,8-Diisopropyl-peri-xanthenoxanthene4,10-quinone; 1-Eicosanol.	[82]
Echinacea species (Echinacea pallida, angustifolia and *purpurea)*	Biplot, HPLC/ESI/MS, GAP	Trideca-2E,7Zdien-10,12-diynoic acid-isobutylamide (DETBA); Undeca-2Z(E),4E(Z)-dien-8,10-diynoic acid-isobutylamide; Undeca-2E (Z)-en-8,10-diynoic acid-isobutylamide; Undeca-2Z-en-8,10-diynoic acid-2-methylbutylamide; Pentadeca-2E,9Zdien-12,14-diynoic acid-isobutylamide; γ-Gurjunene; Germacrene-D; Aromadendren; p-Menth-1-ene-6-ol; Dodeca-2Z,4E-dien-8,10-diynoic acid-isobutylamide.	[83]
Withania somnifera	GC-MS,NMR and HPLC	Palmitic acid; Oleic acid; Linoleic acid; Citric acid; Fructose-5 TMS; Fructose-5 TMS, Fructose-5 TMS, Fumaric acid (L); Glycine (L); Myo-inositol (L); Isoleucine (L); Lactic acid; Malic acid 3 TMS; Lysine; Leucine (L); N-acetyl-glucosamine (L); Phenyl alanine (L); Tartaric acid (L); Benzoic acid (L & R); Butandioic acid (L); Phenyl acetic acid (L & R); β-Sitosterol (L); p-Hydroxy, phenyl acetic acid (R); 3,4,5-Trihydroxy cinnamic acid (R).	[84]
Tinospora cordifolia (Guduchi) in Sanskrit	UPLC-QTOFMS	Mangoflorine; Jatrorrhizine; Columbamine; Berberine; Tinosporoside; Menisperine.	[85]

(continued)

Table 1 (continued)

Indian medicinal plant	Metabolomics analysis approach	Metabolites analyzed	References
Saraca asoca	UPLC-QTOFMS	Prunasin; Ophosphocholine; Delphinidin (antioxidant); (−) Epicatechin; Procyanidin B1.	[86]
Zanthoxylum armatum Commonly known as (Winged Prickly Ash)	UPLC-DAD-ESI-QTOF-MS/MS	Zanthosin; Rubemamin; Horsfieldin; Magnolin or epimagnolin; Isomer of hydroxysanshool; Eudesmin; Armatamide; Fargesin; Xanthoxylin; Kobusin; Sesamin; Dioxamin; Asarinin; Hydroxy-α-sanshool.	[87]
Curcuma longa (turmeric)	LC-ESI-MS	Bisdemethoxycurcumin (curcuminoid); Demethoxycurcumin (beta-diketone); Curcumin; 5-Hydroxy-1,7-bis(4-hydroxyphenyl)-3-heptanone; 11-(4-Hydroxy-3-methoxyphenyl)-7-(4-hydroxy-3,5-dimethoxyphenyl)-4,6-heptadien-3-one; 7-Bis(4-hydroxy-3-methoxyphenyl)-4,6-heptadien-3-one.	[88]
Boerrhaevia diffusa (Red Spiderling)	HS-SPME, headspace solid-phase microextraction	3 Limonene; a-Pinene; 2-Decen-1-ol; 2-Nonen-1-ol; Camphor; Menthol; cis 4-Hexen-1-ol; Geranylacetone; Phellandrene; Isomenthone; Methylpyrrole; β-Cyclocitral; 3-Phenyl-2-(20-pyridyl)-indole; trans 2-Octanal; Vanilin; 4-Oxoisophorone; Resorcinol monoacetate; β-Ionone; Dihydroactinidiolide; Eugenol; Benzothiazol; Benzophenone; Linalyl anthranilate.	[89]
Glycyrrhiza species (*Glycyrrhiza echinate, glabra, inflata* and *uralensis*)	1HNMR, GC-MS and LC-MS, PCA	Rhamnose (glycosides); Isoliquiritigenin; Glycyrrhizin; Liquiritigenin; Hydroxyphenyl acetic acid; Liquiritin; Sucrose; Licochalcone; Isoliquiritin; 4-Licochalcone.	[90]

8 The Advantage of Metabolomics in Herbal Medicine Research

Evaluation of metabolic products is of utmost relevance due to their crucial role as constituents of biochemical pathways, their potential utility as biomarkers for various biological states, and their nutritional significance [55]. Multiple studies have indicated that metabolites have a significant impact on the gene expression regulation and the modulation of an organism's response as a signal to stress and development [91]. Recent progress in characterizing metabolic alterations in unconditional pathways has aided our understanding of how cells prioritize and allocate scarce nutrients. Investigating things at the metabolite level may have an immediate effect on biological performance. In order to determine how effectively herbal medicinal products can treat illness, it can therefore be applied in a promising way in herbal metabolomics. Advantages of this technique are not limited; it is widespread across the world. Some common herbal medicines across the world are listed in Table 2.

9 Promising Ways to Tackle Challenges in Untargeted Metabolomics Studies

Untargeted metabolomics methodologies, such as LC-MS and NMR, offer insights into the structural aspects of metabolites, including stereochemical characteristics. Additionally, these techniques enable rapid, automated, and high-throughput analysis of raw plant extracts, facilitating the quantification of diverse metabolites [92, 102].

NMR	Functions	Overreliance	Challenges	Promising ways to tackle challenges
	NMR provides structural information about the metabolites, but it has very low and poor chemical resolution [103].	The magnetic field's strength affects the NMR signals' sensitivity and intensity.	1. As a result, stronger magnets are needed to enhance the performance of the NMR technique. 2. In the assessment of plant extraction by the utilization of NMR spectroscopy, the substantial resonance overlap may make it difficult to quantify and identify metabolites.	1. The utilization of complementary metal oxide semiconductors in the increased high-throughput NMR spectrometer involves the integration of several interconnected radio-frequency circuits and high-sensitivity micro-coils on a single chip. This integration aims to enhance both sensitivity and

(continued)

				throughput [104]. 2. Numerous NMR investigations using enrichment or fraction step have been successful in overcoming this [105].
LC-MS	Compared to the NMR, the LC-MS platform offers greater sensitivity and selectivity. Additionally, it enables the detection and measurement of metabolites at very low concentrations [106]. Semi-polar phytochemical identification is frequently done using LC-MS. The detection of unidentified spectrum characteristics in the utilization of heteronuclear and multidimensional NMR techniques, such as 31P and 15N, can enhance the efficacy of NMR-based investigations.	When comparing the database, the combination of heteronuclear scalar coupling and chemical shift measurements can provide enough information to identify metabolites.	The proper functional groups can be difficult to identify using chemical shift values.	Hence, more investigation is necessary to confirm the existence of amine functional groups and carboxylic such as through the utilization of pH titrations [107].

10 Conclusion

In light of the strengthening global demand and expanding market for herbal drugs, it is imperative to conduct thorough investigations and get comprehensive insights into the fundamental breakthroughs in this field by leveraging modern research technology. The incorporation of a wide range of analytical instruments, in conjunction with multiple techniques and online bioassays, is helpful for evaluating efficiency. Presently, the drug development process primarily utilizes the reductionist method in order to identify compounds that demonstrate intriguing features. Nevertheless, the successful recognition of active chemicals can be realized by the utilization of the

Table 2 Analytical techniques to identify the components after quantitative analysis by different plant parts or from herbal medicine

Herbal medicine/plant	Plant part	Analytical technique	Components of quantitative analysis	References
Ocimum Sanctum	Entire plant of *Ocimum sanctum*	MS/UPLC-ESI MS	Vanillic acid, Apigenin, Catechin, Sinapinic acid, Quercetin dihydrate. Caffeic acid, Rutin, Ferulic acid, Rosmarinic acid.	[92]
Rabdosiae Rubescentis Herba	*Rabdosiarubescens dried* above ground parts	HPLC-ESIMS/MS	Effusanin, Rosmarininc acid, Quercetin, Rutin, Isorhamnetin, Lasidonin, Chlorogenic acid, Ferulic acid, Salicylic acid, Caffeic acid, Lasiokaurinol, Nodosin	[93]
Decoction Mahuang Fizi	Derived from ephedra Herba, Asari radix et rhizome	HPLC-QQQ MS/MS	Methyl ephedrine, Songrine, Neoline, Talatisamine, Chasmanine, Benzoylmesaconine.	[94]
Injection Shenqi Fuzheng (SQFZ)	Derived from extract of radix astragali and radix codonopsis	UPHPLC-Q-TOF MS	Adenosine, L-phenylalanine, Codnopsine, Tryptophan, Ononin, Fructose, Glucose, Sucrose, Soyasaponin I, Cyclocephaloside II.	[95]
Capsule Wuzhi	Preparation of an herbal extract (ethanolic) of *Schisandra sphenanthera*a deciduous climber (Nan-Wuweizi).	LC-MS/MS	Deoxyshisandrin, Schisandrin, Schisandrol B, Schisantherin A, Schisanhenol.	[96]
Lyophilized injection YiqiFumai (YQFM)	Derived from dried roots and rhizome of ginseng radix. A modern preparation derived from Shengmai powder.	UFLC-IT-TOF-MS	Ginsenosides Re, Ginsenosides Rg1, Ginsenosides Rc, Ginsenosides F2, Ginsenosides R-Rg3, Rh1, Ro, Schizandrol A, B, Gomisin D, Ophiogenin.	[97]

metabolomics approach in combination with multivariate data processing techniques. The utilization of NMR and MS methodologies in recent scientific progress has greatly augmented the capability to assess a wide range of chemical compounds. These developments have moreover bolstered the practice of acquiring data for newly discovered compounds by making use of the open access natural products library. Without a doubt, metabolomics is widely recognized as the most efficient method for assessing the effectiveness of herbal medicines. This methodology effectively captures the diverse range of changes exhibited by the key constituent elements that exert significant influence on the fundamental active elements. The metabolomics approach enables rapid analysis of a diverse array of metabolites. As a result, the product of metabolomics in the realm of personalized medicine is experiencing an upward trend. The approach outlined in this study allows for the correlation between the metabolic profile of individual patients and their distinct responses to a particular herbal medicine. This correlation considers factors such as efficacy, clearance, and toxicity. The utilization of metabolomics approach greatly enhances the process of discovering new leads and identifying targets that have not been previously studied. Metabolic tests possess the capacity to provide valuable insights into both the underlying mechanisms of action and the promising adverse effects. The utilization of tandem mass spectrometry enables the examination of metabolite structures, hence enabling accurate purpose of the mass and fragmentation pattern of plant metabolites.

Abstract

Herbal plants have been valued for their medicinal, flavoring, and aromatic properties for centuries. The global market for medicinal and aromatic plants is estimated to be $62 billion, with demand expected to reach $5 trillion by 2050. Aromatic plants and herbs have been widely cultivated and used for medical purposes not only for humans but for animals as well. According to the World Health Organization, herbal medicines are characterized as substances or products derived from plants that possess therapeutic or other beneficial effects for human health. These herbal remedies can be sourced from one or more plants and may include both raw and processed ingredients. This chapter describes the curative values, botanical characteristics, and climatic and cultural requirements of medicinal plants. These include psyllium husk, black cumin or black seed, stevia, fennel, bishop's weed/carom seeds, sweet basil, holy basil, linseed, and turmeric, all medical plants that are grown worldwide. Despite having a higher market value than major field crops, medicinal plants are not cultivated on the same scale as significant as other crops. One of the major reasons for the globally low production of medicinal plants is the lack of information regarding their suitable cultivable climate and their poor adaptability to growing environments. It is imperative to give careful consideration to the selection of soil and cropping strategies to achieve satisfactory yields of high-quality products while ensuring the preservation of their safety and nutritional value. Physiological ecology is also discussed in this chapter in relation to medicinal plant therapeutic potential and medicinal qualities. It is still necessary to explore and understand the cultural practices necessary to cultivate medicinal plants successfully. This chapter aims to address these gaps by discussing the input requirements, therapeutic value, and suitable cultivation areas for medicinal plants. This chapter aims to fill these knowledge gaps by disseminating insights into cultivation practices and addressing these knowledge gaps. By addressing these gaps and disseminating insights into cultivation techniques, it hopes to develop sustainable and optimized cultivation techniques for medicinal plants. As a result of such advancements, medicinal plants will be available for future generations and will meet the growing demand for them.

Keywords

Climate change effects · Cultural practices · Ecological interactions · Geographical distribution · Herbal plants · Irrigation and nutrient requirements · Phytochemical profiling · Therapeutic or medicinal properties

1 Introduction

Aromatic plants, spices, and herbs are widely used for medical purposes due to their antimicrobial activities, in addition to their flavor and fragrance qualities [1, 2]. The positive effects of aromatic plants, herbs, and their essential oils in various diseases have been evidenced throughout human history [3, 4]. The utilization of herbal remedies for disease treatment is prevalent in nonindustrialized societies across the globe [5]. The advancement of chemical and phytochemical analysis has resulted in a growing reliance on herbal medicine for addressing human ailments. It has been observed that the characteristics of medicinal and aromatic plants can vary significantly based on soil composition. Therefore, careful consideration must be given to soil selection and cropping strategies to ensure the production of high-quality, valuable products that prioritize safety and nutritional value. Medicinal plants require different soil and cropping strategies to obtain superior yield and quality [6]. While sustainable production of raw materials from these plants can be achieved through growth manipulation.

Medicinal plants have the potential for enhancing the consistency, purity, and quality, as well as the biomass production of raw materials [7]. The inconsistent and low availability of high-quality plant raw materials often hinders the sustainable production of various innovatively developed plant-based products. By cultivating these plants, it becomes possible to improve biomass production, ensuring a sustainable supply without compromising the bioactivities of the medicinal plants through the manipulation of growing conditions. For example, the cultivation of *P. sidoides* under well-watered conditions significantly accelerated the biomass, without significant alteration in the content of active compounds [8].

Despite efforts to improve the cultivation of medicinal plants, comprehensive information on production techniques and product biochemical composition and active ingredients of these plants is still lacking, particularly high-quality research data on appropriate cultivation technologies for geologically diverse agricultural systems and ecological zones. Research on promoting innovative cultivation and application technologies for medicinal plants could help improve their yield and quality. Further, understanding the biochemical composition of plant products will assist in identifying suitable allopathic ingredients for disease treatment. A detailed analysis of the relationship between the plant's physiological processes and the production of phytochemical constituents is described in this chapter. Additionally, this chapter examined how various environmental factors, such as light, temperature, and water availability, affect phytochemical synthesis and accumulation. This knowledge will contribute to developing climate-specific crop production technologies for superior growth, yield, and quality of herbal plants. In this chapter, we aim to (1) cover a comprehensive overview of the origins, geographical distribution, and botanical characteristics of medicinal plants, (2) examine their physiological characteristics, phenological devolvement, and chemical composition, with a particular focus on the production process of medicines and (3) therapeutic use of medicinal plants. By bridging the gap between physiological ecology and phytochemical constituent accumulation in medicinal plants, this chapter provides valuable insights for researchers, practitioners, and stakeholders who are involved in the cultivation, processing, and use of medicinal plants.

2 Psyllium Husk (*Plantago ovata*)

The medicinal plant known as psyllium was brought into use by Indian Muslims, who initially gathered its seeds from wild species [9]. Psyllium is an annual plant of the *Plantago* genus, which has around 200 different species. Scientifically known as *Plantago ovata,* it is the most important and known species with a wide variety of uses. It is also called Isabgol, meaning "horse ear," which describes the shape of the seed [10, 11]. In India, psyllium production is 0.432 million metric tons from an area of 0.448 million hectares [12]. Gujarat and Rajasthan states are the major producing states of psyllium because the climatic conditions of these regions are most suitable for psyllium cultivation. *Plantago* ranks sixth in the economic trade of medicinal plants, and India dominates its world market while the United States is the main importer of its seeds and husks, consuming 8000 tons annually [13, 14]. *P. ovata* is a short-stemmed or stemless annual herb having 45–69 flowers with a height of 30–45 cm while leaves are 7.5–25 cm long [15, 16]. The plant has a tap root system with a group of secondary roots. After 60 days of planting, white-colored flowers appear on the flowering shoots. The psyllium is mature and ready to harvest when flower spikes turn reddish brown and lower leaves get dried up. Psyllium husk is the main product of Isabgol. Through mechanical process, the outer skin of the husk is detached, and the husk recovery from seed is about 25–26% [9].

The psyllium husk is the outermost skin of the seed that contains protein (0.94%), ash (4.07%), and total carbohydrates (84.98%) [17]. Linoleic acid (40.6% of the oil recovered from Plantago seeds) and oleic acid (39.1%) each made up a sizeable component of the oil's makeup. In addition, 6.9% of linolenic acid was also found, though in a lesser amount. It is considered a good source of soluble and insoluble fiber. The diet fibers produce low calorie food and are extracted from plants having pharmaceutical properties [18]. All the properties show the nutritional and medicinal values of *plantago ovata* [19].

2.1 Effects of Abiotic Stresses

Environmental variations limit the growth, physiology, and geographical distribution of plants. Seed germination and growth of *Plantago ovata* are affected severely in alkaline soils and hot climates, for example, air temperature $> 30\ ^\circ\mathrm{C}$ [20]. The high-temperature stress reduces the yield by affecting the photosynthetic rate and plant cell metabolism [21]. Drought stress increases the soil salinity, which inhibits the cell function and pharmaceutical properties of plants [22, 23].

2.2 Cultural Practices and Management

P. ovata generally grows in semi-arid to arid environments under the cold season (October–March) in poor fertile sandy-loam to loamy soils [16, 24]. The optimum temperature ranges between 15 °C and 30 °C, and the ideal soil pH ranges between 4 and 6 for maximum seed germination and plant growth [25]. Before sowing, seeds are treated with fungicide to control root rot disease while nitrogenous and potash fertilizers should be used in a balanced way [26]. The two main insects of *P. ovata* are aphids and white grubs while downy mildew and Plantago wilt are the major diseases [27]. *P. ovata* is a 119- to 130-day-crop, and its harvesting starts when flower spikes turn reddish brown, upper leaves turn yellow, and lower leaves dry up [28]. Psyllium husk has shelf life of 6 months, and the husk recovery from seeds is around 25–26% [9].

2.3 Phytochemicals

The presence of phytochemicals in *Plantago ovata* shows its importance for different industries and in anti-inflammatory activities [29]. Numerous metabolites are found in their seeds and used to treat different diseases (Table 1).

Table 1 Chemical constituents of Plantago ovata seeds

Source	Group	Constituents	References
Seed	Primary and secondary metabolites	Fumaric acid, malic acid, stearic acid, linoleic acid, linoleic acid, kaempferol, glucose, acetic acid, sucrose, fructose, xylose, formic acid, GABA as γ-amino butyric acid, citric acid, glutamine, cystine, valine, glutamic acid, alanine, tyrosine succinic acid, glycine, leucine, and lysine	[30, 31]
Seed coat	Hydrocolloid	Lrhamnose, L-arabinose, galacturonic acid, D-galactose, and D-xylose	[32]

2.4 Geographical Distribution

Psyllium husk originated from the Mediterranean region and is now used in North Africa, Russia, and central and southwest Asia in different herbal medicines [33, 34].

3 Black Cumin or Black Seed (*Nigella sativa*)

Black cumin, also called black seed, roman coriander, or kalonji, is the annual plant and belongs to the ranunculus family (Ranunculaceae) grown for its pungent seeds, which are used as a spice and in herbal medicines. Black cumin sowing and reaping have been mentioned in the Holy Bible, and The Prophet Mohammed (PBUH) declared it as the remedy for all diseases, except death. Black cumin cultivation was reported more than 3000 years ago in the tomb of Egyptian King Tutankhamun [35] and was spread in North Africa, the Middle East, South Asia, Eastern Europe, North America, the Mediterranean, Russia, Turkey, and France, where its seed was used in medicine, bread, and cakes [36]. In traditional foods as well as baked goods, where it is used to enhance flavor and taste, black cumin is used as a food preservative and a spice [37]. Black cumin essential oil contains significant amounts of carbohydrates, proteins, and lipids, which indicate the nutritional value of black seeds [38]. India is the largest grower of black cumin with an area of 6.24 m ha and production of 254 thousand tons, followed by Turkey with an area of 0.81 m ha and production of 689 thousand tons [39].

Black cumin is a tall annual plant, typically ranging from 20 to 60 cm in height. It features an upright growth habit, with a branching stem and a taproot system [40, 41]. The flowers are hermaphrodite and often cross-pollinated that are solitary on the main axis [42]. During the initial stages of blooming, the flower exhibits a pale green coloration in its petaloid sepals. However, upon reaching full bloom, the color transforms into a distinctive pigeon blue shade [43]. On average, approximately 10% of the flowers are infertile. The flowers lack bracts as involucres, and the peduncle is elongated and upright. The sepals of the flower are petal-like and have a wide, ovate shape. They are arranged in a single whorl, typically consisting of 4–6 sepals [44]. Once mature, the fruit, in the form of a capsule composed of 3–7 united follicles, contains numerous minuscule seeds [35].

The seeds of black cumin have a distinct triangular shape, featuring a flat side and a convex side [45]. Black cumin oil contains tocopherol, phenolic compounds, thymoquinone, and antioxidants, and it has a great market for pharmaceutical applications [46]. The essential oil can be used in the cosmetics industry due to the presence of a high amount of thymoquinone in the oil [47].

3.1 Effects of Abiotic Stresses

Sudden changes in the environment during the crop growth period affect the pharmacological and pharmaceutical activities of black cumin [48]. The abiotic stresses like drought and salinity produce free radicals in black cumin, which disrupt the osmotic balance and plant metabolism [49].

3.2 Cultural Practices and Management

Black cumin grows well in cool and dry weather, which favors flowering and seed setting. It is sown on ridges and beds, but a better yield has been obtained from bed sowing with a seed rate of 20 kg ha^{-1} [50, 51]. The seeds are soaked in water before sowing. Cumin is relatively drought tolerant, but the availability of water at the reproductive stage increases grain yield and 120- to 400-mm rainfall is sufficient during the season [52, 53]. The ideal temperature for its cultivation is 12–14 °C, but it can grow well up to 25 °C [35]. Black cumin requires low fertilizer, but moderate fertilization is important to get optimum yield, while its deficiency may lead to yield reduction [54]. The amount of NPK at the rates of 50, 40, and 20 kg/ha, respectively, is recommended for a good yield of black cumin [55]. Full sunshine during vegetative growth increases plant growth and lead development and direct sunlight is required at flowering stage [36]. Weeds have the potential to significantly diminish crop yield, with reductions ranging from 60% to 85%. It is recommended to conduct 3–5 weeding at intervals of 20–25 days in order to ensure a weed-free environment throughout this crucial period [56, 57]. Caterpillars and armyworms are the major insects of black cumin that can be controlled through 5% aldrin solution and 0.05% methyl parathion mixture, respectively [58]. Major diseases of black cumin are fusarium wilt (yield loss up to 72%), blight (yield loss up to 88%), and powdery mildew (yield loss up to 60%), which can be controlled by treating the seeds with fungicides [58].

3.3 Chemical Constituents

Black cumin is used in various traditional medicines due to its certain chemical constituents [59, 60] (Table 2).

Table 2 Chemical constituents of black cumin

Chemical groups	Subgroup	Active constituents
Fixed oil	Saturated fatty acids	Palmitic acid and stearic acid
	Unsaturated fatty acids	Oleic acid, eicodadienoic acid, dihomolinoleic acid, and linoleic acid
Terpenes	Isoquinoline	Nigellicimine and nigellicimine N-oxide
	Aliphatic	Citronellol, carvacrol, limonene, dithymoquinone, 4-terpineol, p-cymene, carvone, α-pinene, thymohydroquinone, thymoquinone, and anethol
Amino acids	Essential amino acids	Tryptophan, phenylalanine, lysine threonine, leucine, valine, isoleucine, and histidine
Phenolics	Acidic phenolics	Syringic acid, p-coumaric acids, vanillic acid, and hydroxybenzoic acid
Metals	Trace elements	Phosphorus, calcium, iron, potassium, and zinc
Saponins	Triterpenes	Steryl glucosides and acetyl-steryl-glucoside
Flavonoids	Flavonoidal glycoside	3-Galactosyl glucoside, Kaempferol 3-glucosyl galactosyl glucoside, and trigillin quercetin-3-glucoside quercetin

3.4 Geographical Distribution

Black cumin has been used for many years to treat many illnesses in both humans and animals [61, 62]. In addition to Western and Southern Europe, it is used in North Africa, the Mediterranean basin, and Western and Southern Asia [63, 64].

4 Stevia (*Stevia rebaudiana*)

Stevia rebaudiana (Bertoni) is a herbaceous perennial plant that belongs to the Asteraceae family. It originated in Paraguay (South America) and is commonly known as honey leaf, sweet leaf, sweet weed, or sweet herb. Stevia was introduced as an alternative sweetener for the first time in Japan when saccharin was banned [65], although the commercial cultivation of stevia was started in Paraguay in 1964 [66]. Stevioside, the major sweetener present in leaf and stem tissues of stevia, was first considered as a sugar substitute in the early 1970s by a Japanese consortium formed to commercialize stevioside and stevia extracts [67]. During World War II, Stevia was used as a sweetener to combat food shortages in Britain. Diterpene glycosides produced by stevia leaves are noncaloric and more sweetener than sucrose [68]. Subsequently, stevia was marketed in Latin America, Canada, China, Japan, Indonesia, and the United States [69]. Stevia is mainly cultivated in Japan, China, Taiwan, Thailand, Korea, Brazil, Malaysia, and Paraguay. China has a 75% share in stevia cultivation, and it is cultivated on an area of 32,000 hectares worldwide. Stevia grows up to a height of 65–80 cm as it is a small perennial shrub [70]. The roots are the only part of plants that do not contain stevioside (sweetness) and are fibrous, filiform, and perennial in nature [71]. Stevia is an insect-pollinated plant [72, 73], and the seed is called achene having feathery pappus. Stevia is very popular in many regions of the world and is expected to become a major source of high-potential sweeteners. The sativoside sugar in leaves has no calories and has a large market [74]. It became economically important owing to its major contribution to the sugar industry, which generously uses its highly sweet leaves to sweeten beverages and make herbal tea as well. This popular plant's leaves have a wonderful sweetness that makes them a great option for people managing their intake of sugar and carbohydrates. The leaves can also be used as a color and flavor enhancer as well as a sweetener in teas and salads [75].

4.1 Effects of Abiotic Stresses

Stevia plants have some resistance against salinity and could control the reactive oxygen species through the production of antioxidants [76]. The abiotic stresses for a short duration increase the biosynthesis of steviol glycosides while the prevalence of these stresses for a long time affects the photosynthetic rate and elongation of shoots. Long-term drought stress decreases the protein and chlorophyll content of leaves due to the increased activity of proteases [77]. High-temperature stress and hot climate result in early flowering of stevia plants, which results in low yield [78].

4.2 Cultural Practices and Management

The ideal climate for Stevia is semi-humid subtropical, ranging from 6 °C to 43 °C, with an average temperature of 23 °C [79]. The synthesis of terpenes in stevia plants is affected by climatic and environmental factors [80]. Stevia yield and quality are affected by temperature and photoperiod. Temperature, length, and intensity of the photoperiod have a significant impact on the growth, quality, and secondary metabolites of stevia plants, and higher yields are recorded in summer crops than in winter crops [81]. When the temperature drops below 20 °C and the day length decreases by 12 hours, vegetative growth significantly reduces. Vegetative propagation with a stem having two leaves is used for multiplication because of low seed germination in stevia. Plant growth and stevioside content in the leaves of the plants grown from stem tips were more uniform than in plants grown from seeds [82]. In Pakistan, the best time of sowing for stevia seedlings is December–January or August–September and the seedlings can be transplanted after 2 months, while the concentration of stevioside is higher in January sowing plants [83]. Planting density and transplanting date are the most important agronomic factors that may affect the quality and quantity of yield. Stevia herb is very sensitive to water stress, thereby frequent irrigation in summer at an interval of 3–5 days is useful to avoid the effects of drought and heat stress; sprinkler irrigation gives better results [84]. Balanced soil nutrition increases the contents of steviol glycosides in stevia tissues, although this crop can be sown on poor quality soil [85, 86] while the deficiency symptoms of N, P, and K appear on stevia leaves. Nutrient requirements of this crop are low to moderate since this crop is adaptable to poor-quality soils in its natural habitat. Stevia has a poor capacity to compete with weeds during the initial growth period, which limits the crop yield more than any other factor. However, using black plastic mulch and increasing plant densities inhibit the weeds population [87]. Because of the presence of the inherent sweetness that acts as an insect repellant, no insect attack has been reported in stevia; therefore, no insecticide has been used in this crop, making this crop organic stevia. Moreover, several diseases such as alterneria leaf spot (*Alternaria alternata*), stem rot (*Sclerotium dephinii* Welch.), root rot (*Sclerotium rolfsii*), powdery mildew (*Erysiphe cichoracearum* DC), damping-off (*Rhizoctonia solani* Kuehn.), *Sclerotinia sclerotoirum,* and *Septoria stevia* (leaf spot) attack this crop. Neem-based pesticides give good results in integrated disease management [88–90]. Stevia leaves, along with stem tips, are harvested 4 months after transplanting, and the subsequent harvesting is taken 3 months after the first harvest. The best time to harvest is mid-September to late September when plants attain 50–70 cm height (before flowering) to get maximum steviol glycoside contents [91]. Three commercial cuttings are taken, leaving only a 10 cm stem after each cutting to get a better subsequent flush [84].

4.3 Chemical Constituents

Table 3 shows the chemical constituents of Stevia leaves.

Table 3 Chemical constituents of Stevia leaves

Plant part	Group	Constituents	References
Stevia leaves	Phytochemicals	Chlorogenic acids, folic acid, austroinullin, stevioside, β-carotene, non-glycosidic diterpenes, steviol, thiamine, riboflavin, glucoside, niacin, anthraquinones, rebaudi, vitamin C, oxides, and flavonoids	[92, 93]
	Complex compounds	Rebaudioside, diterpene glycosides-stevioside, rebaudioside A, dulcoside A, rebaudioside C, and steviolbioside	[94, 95]

4.4 Geographical Distribution

Stevia is mainly grown in the northeast regions of South America [96] and is also used in China, Japan, Korea, and India.

5 Fennel (*Foeniculum vulgare*)

Foeniculum vulgare is an aromatic annual medicinal herb that belongs to the family Apiaceae commonly known as fennel. This herb is native to Southern Europe and the Mediterranean region where it is grown as an important cash crop. India dominates the economic market of fennel and exports it as seed, powder, and volatile oil to the United States, Singapore, the United Kingdom, the United Arab Emirates, Sri Lanka, Malaysia, Saudi Arabia, and Japan [97]. Fennel is an erect, glaucous green plant, having a height of 3.3–12 feet with a smooth, bright green and hollow stem [98]. Fennel is a branched herb that has hairy, feathery, and soft foliage and contains greenish gray, ovate, ribbed, and approximately 6–10-mm-long fruit. Due to its flush foliage and seeds, it is grown in vegetable gardens and harvested for its usage in cooking. The leaves are 40 cm long and 0.5 mm wide and are branched and cut into fine segments. The flowers are present on terminal compound umbels with each umbel containing about 20–50 tiny yellow flowers on the pedicels. The pericarp contains essential oil and the spicy licorice fragrance present in the whole plant.

5.1 Effects of Abiotic Stresses

Drought and high-temperature stresses in arid and semi-arid areas are major issues of yield reduction of different plants [99]. Hot climate and water shortage affect the photosynthetic rate, quality, and quantity of essential oil and decrease the vegetative growth and yield of fennel [100]. High-temperature stress alters physiological processes like photosynthetic and transpiration rates, which negatively affects the growth and development of fennel plants [101].

5.2 Cultural Practices and Management

Fennel likes cool and dry seasons and a temperature of 15–20 °C for optimal growth and production, so high temperature during flowering results in low grain filling. The loam soils and the soils that are rich in organic matter are best while sandy soils are not suitable for its sowing. Waterlogged and salt-affected soils are not suitable for their cultivation, and appropriate drainage is required for proper growth of fennel [102]. Fennel is sown from mid-September to the first week of October and 18 °C is the ideal temperature for germination [103]. Hydro priming of seeds for 8–12 hours before sowing results in better germination and good seedling establishment and seeds are sown at 1.5–2 cm depth. It can tolerate a soil pH of 4.8–8.3 and can be grown as an intercrop with other crops. To cultivate it through transplanting, about 2.5 kg of seed is required for each hectare of nursery while 10 kg/ha is required for direct seeding of the crop. Maximum grain yield was obtained at 20 × 15 spacing [104]. Fennel requires 90 kg N, 40 kg P_2O_5 and 30 kg K_2O and 15 tons of farmyard manure per hectare for good crop yield. If plants seem weak after 3–4 weeks of sowing, 1% urea should be applied exogenously for better crop stand. The application of phosphorus-solubilizing bacteria increases the seed yield as well as essential oil content in fennel seeds [105]. The critical period of weed competition in fennel is the first 50 days [106], and irrigation is applied at 10-day intervals depending on crop requirement [107]. *Leveillula taurica* (powdery mildew), *Ramularia foeniculi* (Ramularia blight), *Cercospora foeniculi* Magn (Cercospora blight), *Ascochyta foeniculum* Mc Alpine (Ascochyta blight), *Rhizoctonia solani* (Rhizoctonia root rot), *Alternaria alternata* (Alternaria blight), *Pythium aphanidermatum* (damping off of seedlings), and *Plasmophara nivea* (Casparg) Schroeter (Downy mildew) are important diseases of fennel [108]. Thrips are the main insect of fennel. Fennel umbels are harvested 4–5 times. Before full ripening, when the umbels change their color from deep green to slightly yellow, they are plucked, and the umbels are dried in shade by avoiding their heaps. Afterward, umbels are threshed to separate the seeds by winnowing [109].

5.3 Chemical Constituents

Some of the essential oil and chemical constituents of Fennels leaves are shown in Table 4.

Table 4 Average essential oil and chemical constituents of Fennels leaves

Plant parts	Constituents	References
Essential oil	A-phellandrene, fenchone, trans-anethole, methyl chavicol (estragole)	[110]
Fennel seeds	Terpenoids, fat, alkaloids, minerals, protein, saponins, carbohydrates, fiber tannins, carotenoids, cardiac glycosides, polyphenols, flavonoids, glycosides, and vitamins like K, E, C, and A	[111]

5.4 Geographical Distribution

Fennel originated from Mediterranean areas and now it is grown and used in Russia, India, China, and Japan [112, 113]. In Europe and Mediterranean areas, it is used as antispasmodic, diuretic, anti-inflammatory, analgesic, secretomotor, secretolytic, galactagogue, eye lotion, and an antioxidant agent [114].

6 Bishop's Weed/Carom Seeds (*Trachyspermum ammi*)

Bishop's weed, belonging to the family Apiaceae, is a herbal medicinal plant and has some secondary metabolites with potential bioactivities. It is used as an anti-inflammatory, antibacterial, antifungal, antiviral, and anticancer agent [115]. Bishop's weed originated from Eastern Mediterranean and spread to India during the Greek conquest of Central Asia [116]. Now, it is grown as an important spice and aromatic herb all over the world, including in the Middle East and Asia [117]. Bishop's weed is a grassy, aromatic annual herbaceous plant with an erect stem that reaches up to a height of 90 cm. The seeds are 2 mm long and 1 mm wide and are grayish brown, ovoid in shape, aromatic in odor, and pungent in taste [118]. Carom seeds have fiber 21.8%, protein 17.1%, and minerals 7.9% (Ca, P, Na, and riboflavin). India is the major producer of Bishop's weed with a production of 28,973 tons from an area of 41,134 ha [119]. The demand and area under cultivation of carom seeds have increased over time due to their usage in herbal medicines and cosmetics [120].

6.1 Effects of Abiotic Stresses

Different biotic and abiotic factors affect the chemical composition of this medicinal plant. Drought stress affects the chlorophyll contents, phenolic compounds, and net carbon dioxide assimilation rate in bishops weed plants [117].The high-temperature stress limits the thymol and some other phytochemicals in the essential oil of carom seeds [121].

6.2 Cultural Practices and Management

Bishop's weed is grown in arid and semi-arid climates of the world and is sown from October to November [122]. The optimum temperature for its growth ranges from 15 °C to 25 °C with 65%–70% relative humidity [118]. Well-drained loam soil is best for this crop as this crop is severely affected by heavy rainfall and waterlogging. It is typically grown in the winter season between October and November, has flowers and fruits from January to April, and is harvested in May and June. A shallow soil cultivation with a fine-seed bed is required for better germination and 10–15 ton/ha well-rotten farmyard manure should be applied before the last plowing. About 3.5–4 kg

Table 5 Chemical found in Carom

Plant part	Constituents	References
Carom seeds	38.6% carbohydrates, 11.9% fiber, 15.4% protein, 18.1% fat saponins, flavone, glycosides, nicotinic acid, tannins and minerals such as iron, calcium, and phosphorous	[124–126]
Essential oil of carom seeds	Styrene, δ-3-carene, β-pinene, terpinene-4-ol, α-phyllanderene, β-phyllanderene, carvacrol, α-pinene, γ-terpinene pcymene, and 35–60% thymol	
Fruit of bishops weed	Carotene, iron, chromium, calcium, iodine, zinc, copper, manganese, cobalt, thiamine, phosphorus, and riboflavin	

per acre of seed is required in drill sowing and 2 kg of seed per acre is required in manual sowing of seed on beds. The plant-to-plant distance is maintained at 6 inches while row to row distance is maintained at 2 feet and the crop is usually cross-pollinated [122]. Three to four irrigations are required for this crop without missing irrigation at flowering and grain filling, and 80 kg nitrogen and 50 kg phosphorous are required for successful crop growth. The Rabi weeds compete with this crop for the first 54 days, and two weeding at an interval of 15 days are performed to reduce the weed population. Aphids, jassids, stem flies, and seed bugs are major insects of this crop while bacterial blight, root rot, and powdery mildew are the major diseases of this crop. The newly developed varieties should be grown and the optimum plant population should be maintained for weed and insect control while some copper-containing fungicides are used to control the disease infestation [123].

6.3 Chemical Constituents

The chemicals present in Carom are presented in Table 5 and includes carotene, thiamine, cobalt, etc.

6.4 Geographical Distribution

Bishop's weed originated from the Middle East. It is grown and used in Egypt, Iran, Iraq, India, Pakistan, and Afghanistan [127].

7 Sweet Basil (*Ocimum basilicum*)

Sweet basil, belonging to the family Lamiaceae, is an aromatic herb that originated in India. This culinary herb, also known as the "king of herbs," is being grown commercially in Iran, Africa, Italy, Belgium, Hungary, France, Spain, Bulgaria, Poland, and the United States [128–130]. Since the last few years, North America has been the largest producer of basal leaves with a 51.23% share in the world market while the Asia Pacific contributes 37.87% and Europe contributes 4.35%. The market value of basal is projected to increase from 57 million USD in 2020 to 62 million USD in 2026. Basil is a fragrant erect-type plant that goes up to a height of 62–90 cm. The stem has strongly scented green or violet leaves while white or pale purple flowers of three blooms appear in the form of branch racemes [131]. The world's leading suppliers of basil leaves in the world market are McCormick, Litehouse, Fresh Origins, Frontier Natural Products, and Herbs Egypt. *O. basilicum* contains linalool (43.78%), eugenol (13.66%), 1, 8-cineole (10.18%), methyl chavicol (81.82%), β-(E)-ocimene (2.93%), and α-(E)-bergamothene (2.45%) [132].

7.1 Effects of Abiotic Stresses

The synergistic effects of drought, salinity, and high-temperature stress limit the photosynthetic pigments and other physiological processes of plants of sweet basil. Drought stress causes alteration in the metabolism of plant leaves and water shortage increases the salinity issues in soil, which leads to oxidative stress, resulting in low yield of sweet basil [133, 134]. The high-temperature stress decreases the chlorophyll contents of leaves and plant produces glycine betaine and proline as secondary osmolytes, which plays a vital role in osmoregulation adjustment of plants [135].

7.2 Cultural Practices and Management

The genus *Ocimum* has more than 150 species, 30 of which are grown in tropical to subtropical areas, and some are grown in temperate areas. Environmental factors such as drought, frost, and cold stresses affect the oil composition while the ideal plant growth takes place from 7 °C to 27 °C. Well-drained loamy fertile soil having a sufficient amount of organic matter is required for this crop, although it can grow in saline soils [136]. For 1-hectare nursery, about 200–300 g of seed is sufficient, and the nursery is sown at the end of February and is transplanted on well-drained raised beds 6 weeks after sowing. Plants are transplanted at 40 × 40 cm spacing. *Ocimum basilicum* requires 12–15 irrigations with the first irrigation at the time of nursery transplantation, and four irrigations are applied in summer. The weeds competition period is for the first 2 months, and to control the weeds, the first weeding is done 1 month after nursey transplanting while the second hoeing is done 4 weeks after the first hoeing [137]. Leaf roller and lacewing are the major insects of *Ocimum basilicum,* whereas powdery mildew (*Oidium* spp.), root-rot (*Rhizoctonia bataticola*), and seedling blight (*Rhizoctonia solani*) are the major diseases of this crop.

7.3 Chemical Constituents

The essential oil of sweet basil contains α-terpineol, α-bergamotene, α-bisabolol, α-cariophylene, α-copaene, α-guaiene, β-elemene, β-cadinene, β-cariophylene, β-farnesene, estragol, ocimene, eucalyptol, linalool acetate, menthol, eugenol, menthone, bornil acetate, germacrene-D, camphor, cubenol, elixen, eugenol, cyclohexanone, cyclohexanol, nerol, and myrcenol [138]. The plant leaves also have some chemical constituents like alkaloids, terpenoids, flavonoids, saponin glycosides, tannins, and ascorbic acid [139]. The chemical analysis of essential oil also revealed the presence of the following constituents [140] (Table 6):

Table 6 Chemicals found in Ocimum

Chemical groups	Constituents
Phenylpropene	Syringing, glycoside esculin, and estragole
Coumarin	P-coumaric acid, aesculetin, and coumarin
Oxygenated sesquiterpenes	Nerolidol, cubenol, dihydroactinidiolide, viridiflorol, isospathulenol, caryophyllene oxide, zpathulenol, muurolol, α-cadinol, alloaromadendrene, α-humulene oxide, β-basibolol, β-eudesmol, and β-basibolol
Flavonoids	Kaempferol, isoquercetrin, quercetin, 3,5-pyridinedicarboxylic acid, galactoside, quercetin-3-O-a-L-rhamnoside, kaempferol-3-O-B-D-glucoside, quercetin-3-O-B-D-glucoside-2″-gallate, quercetin-3-O-diglycoside, kaempferol-3-O-rotinoside, 2,6-dimethyldiethyl ester, quercetin-3-O-B-D-glucoside, and quercetin-3-O-(2”-O-galloyl)-rutinoside
Triterpene	Alphitolic acid, basilol, ocimol, betulin, oleonolic acid, 3-epimaslinic acid, ursolic acid, betulinic acid, pomolic acid, and euscaphic acids
Aliphatic ketones	3-Hydroxy-2-butanone, 6-Methyl-5-heptenone, cis-Jasmone, and β-ionone
Aromatic compounds	Anisaldehyde, benzaldehyde, anethole, ethyl cinnamate, safrole, methyl cinnamate, benzyl alcohol, methoxycinnam aldehyde, p- phenethyl alcohol, cumin aldehyde, estragole, methyl benzoate, methyl eugenol, methyl salicylate, phenyl acetaldehyde, and 4-allylphenol
Aliphatic alcohol	1-penten-3-ol, 1-octen-3-ol, 3-hexanol, 2-pentenol, hexanol, cyclohexanol, and octanol
Sesquiterpene hydrocarbons	Aromadendrene, bicyclogermacrene, valencene, caryophyllene, calamenene, bicycloelemene, cadinene, α-copaene, germacrene-a, α-humulene, α-acoradiene, α-(z)-bergamotene, α-cedrene, α-cubebene, α-guaiene, α-amorphene, α-ylangene, α-bulnesene, δ-cadinene, α-cadinene, α-bisabolene, α-gurjunene, γ-gurjunene, α-zingiberene, β-acoradiene, β-ocimene, β-bourbonene, β-caryophyllene, β-elemene, β-cedrene, β-copaene, β-selinene, β-cubebene, β-guaiene, β-farnesene, germacrene-b, germacrene-d, iso-caryophyllene, isoledene, longifolene, α-bergamotene, β-farnesene, β-ocimene, γ-terpin, γ-muurolene, and γ-cadinene
Monosaccharide	D-xylose, L-arabinose, and L-rhamnose
Monoterpenes	Pinocarvone, ocimene oxide, iso-pinocamphone, fenchone, menthol, eugenol, myrtenol, α-myrcene, hotrienol, α-phellandrene, linalyl acetate, α-pinene, α-fenchyl acetate, α-terpinolene, β-phellandrene, β-pinene, camphene, myrtenal, limonene, myrcene, p-cymene, sabinene, terpinolene, thujene, γ-terpinene, α-citral, α-terpineol borneol, bornyl acetate, camphor, carvacrol, carvone, L-camphor, 1,8-cineole, cis-linalool oxide, lavandulol, cis-rose oxide, citronellol, endo-fenchol, estragol, exo-2-hydroxycineole-acetate, geranial, geraniol, geranyl acetate, iso-neomenthol, trans-pinocamphone, L-carvone, linalool, cis-furanoid, and methyl chavicol

7.4 Geographical Distribution

Sweet basil originated from India and has been used in Unani and Ayurvedic herbal medicines since ancient times [141]. It is used as a culinary herb and is widely cultivated in Iran, Africa, Italy, Belgium, Hungary, France, Spain, Bulgaria, Poland, and the United States [130].

8 Holy Basil (*Ocimum tenuiflorum*)

Holy basil (*Ocimum tenuiflorum*) is an aromatic herb belonging to the family lamiaceae and is known as the Queen of Plants and the Mother Medicine of Nature [142, 143]. Out of 150 genera of *Ocimum,* only holy basil or tulsi (*Ocimum tenuiflorum* L.) and sweet basil (*Ocimum basilicum*) have culinary and religious uses [144]. Holy basil originated in India and is grown throughout Asia, Northern and Eastern Africa, Malaysia, South and North America, Taiwan, Hainan Island, and China [145, 146]. Holy basil is cultivated both for essential oil and medical purposes [140]. In India, about 250–300 tons of oil is extracted annually from an area of 25,000 acres [147]. Holy basil shrubby plant has a hairy stem and green- to purple-colored leaves, and it attains a height of 30–60 cm. The leaves reach a length of 5 cm while the flowers are purple that are arranged in racemes [145]. The leaves of holy basil contain 0.7% volatile oil, which has 71% eugenol and 20% methyl eugenol. Furthermore, the oil contains sesquiterpene hydrocarbon caryophyllene, fatty acids, carvacrol, phenolics, flavonoids, linoleic, sitosterol, mucilage, terpenoids, and polysaccharides [148].

8.1 Effects of Abiotic Stresses

Environmental factors like cold, drought, salinity, and flooding have an adverse impact on the growth and development of holy basil plants. Plants develop physiological and biochemical homeostasis against abiotic stresses. Cold stress prior to flowering has drastic impacts on the eugenol contents of the essential oil of holy basil [149]. Excess rainfall or water logging increases the activity of 1-aminocyclopropane-1-carboxylic acid in submerged roots, which impacts the biochemistry and physiological processes within the plant body of holy basil [150].

8.2 Cultural Practices and Management

The tropical climate, along with long days and high temperature, favors the growth of holy basil, and it can be grown in any soil except salt-affected and water-logged soils [151]. Light spectrum, nutrients, water, and temperature affect the growth,

Table 7 Chemical constituents of holy basil

Plant part	Constituents	References
Seeds	β-Sitosterol, fixed oil, mucilage, and polysaccharides	[152, 153]
Fruit	Carbohydrates, β-carotene, protein (30 kcal), fat, insoluble oxalates, vitamin A, vitamin C, and chlorophyll	[154]
Leaves	Gallic acid, volatile oil, vanillin, carotenoids, derivatives of eugenol, ursolic acid, phenolics, flavonoid, ascorbic acid, riboflavin, vanillic acid, thiamine terpenoids, fatty acid, and rosmarinic acid	[155]

yield, and oil contents of holy basil, although it can tolerate frost and drought up to a certain extent [136]. Holy basil is sown on a well-prepared bed or ridge, and ridge-to-ridge distance is maintained at 2 feet distance. Holy basil is sensitive to water deficiency, and 2–3 irrigations are applied at an interval of 1 week while the remaining irrigations are applied at an interval of 2 weeks. The first 2 weeks are important for weed control, and the first hoeing is done 1 week after transplanting while the second hoeing is done 4 weeks after the first hoeing [137]. Leaf rollers and lacewings are the important insects of holy basil while powdery mildew (*Oidium* spp.), root-rot (*Rhizoctonia bataticola*), and seedling blight (*Rhizoctonia solani*) are important diseases of holy basil.

8.3 Chemical Constituents

The chemical constituents of holy basil is presented in Table 7.

8.4 Geographical Distribution

Holy basil originated in India, and now it can be found across tropical and subtropical areas of Asia, Northern and Eastern Africa, Malaysia, South and North America, Taiwan, Hainan Island, and some regions of China [145, 146, 156].

9 Linseed (*Linum usitatissimum*)

Linseed belongs to the genus Linum and to the family Linaceae. It originated from the Fertile Crescent, a region east of the Mediterranean Sea and toward India [157]. Worldwide, about 3180 thousand tons of linseed are produced from an area of 3270 thousand hectares. Linseed is mainly produced in Russia (23%), China (12.4%), Canada (19.8%), Ukraine (3.2%), the United States (7.5%), India (4.3%), Kazakhstan (19%), Ethiopia (3.0%), the United Kingdom (1.6%), France (1.5%), Sweden (0.6%), Argentina (0.6%), Brazil (0.4%), Belgium (0.3%), and Poland (0.3%) [158]. Linseed attains a height of 30–120 cm having slender, green, and glabrous stems with some secondary branches near the top of the stem. The plant completes its life cycle from 90 to 150 days while the seed matures in 30–60 days after flowering [159]. The seeds of linseed contain 20–24% polyunsaturated fatty acids, 42% oil contents, 5–9% carbohydrates, 15–19% protein contents, 5–9% crude fiber, and 2–4% ash contents [160].

9.1 Effects of Abiotic Stresses

Different abiotic stresses like drought, high temperature, salinity, and flooding affect the productivity of linseed. Drought stress occurs when humidity in the air is low and soil moisture is not enough for good plant growth and development. Drought stress at the vegetative growth stage decreases the photosynthetic assimilation rate and quality of essential oil of holy basil [161]. Heat stress for five or more days at the reproductive stage decreases the pollen viability and seed setting of linseed [162].

9.2 Cultural Practices and Management

This crop grows better in temperate climates having high humidity but moderately warm conditions [163]. A temperature of 10–30 °C, average relative humidity of 60–70%, and rainfall of 150–200 mm throughout the crop growth period are suitable for linseed growth [164]. A well-drained fertile soil is suitable for linseed [165]. Seed is sown manually or with a small seed drill with a seed rate of 19.75 kg per hectare in rain-fed areas and 14.8 kg per hectare in irrigated areas. This crop requires fewer irrigations with the first irrigation 3 weeks after sowing, and the subsequent irrigations are applied at flowering, pollination, and seed setting. Seed canary grass and common wild oat are the major weeds of this crop that compete for resources with major crops. Aphid is the major insect of linseed while rust, crinkle, curly top, fusarium wilt, gray mold, alternaria blight, and powdery mildew are the diseases of this crop [166].

9.3 Chemical Constituents

The chemical constituents of linseed is presented in Table 8.

Table 8 Chemical found in linseed

Plant part	Constituents	References
Linseed oil	Dotriacontane, 2-palmitoylglycerol, palmitoyl chloride, squalene, palmitic acid, oleic acid, tetradecanoic acid, methyl tetradecanoate, isopropyl myristate ethyl myristate, palmitoyl chloride, and methyl palmitate	[167]
Seeds	Protein, omega-3 fatty acids (*alpha*-linolenic acid), lignin, and dietary fiber	[168]
Fruit	Carbohydrates, phenolic compounds, proteins, alcaloids, flavonoids, terpenoids, glycosides, and saponins	[169]

9.4 Geographical Distribution

Linseed is grown in Canada, Ethiopia, India, and China and is exported to different areas of the world [165].

10 Turmeric (*Curcuma longa*)

Turmeric belongs to the genus *Curcuma* and the family Zingiberaceae [170]. It is a perennial plant that originated from Asia, Australia, and South America. It is also known as Indian saffron or golden spice due to the brilliant yellow color of its rhizome, which makes it an important spice. Turmeric is a rhizomatous herbaceous plant that originated in India and is cultivated throughout the world [171]. Out of more than 1.1 million tons of world annual production, India's share is 80% [160, 172, 173]. Over the last decade, the consumption of turmeric has increased due to awareness about its benefits for health as it contains valuable compounds called curcuminoids [174]. As an Asian spice, it is cultivated in India, China, Indonesia, Pakistan, Bangladesh, Malaysia, Haiti, Taiwan, and El Salvador [156]. India is the biggest exporter of fresh rhizomes and powder turmeric throughout the world [175]. Turmeric has yellowish to orange-scented rhizomes and can reach up to a height of 1 m. The leaves are arranged in two alternate rows while the rhizomes are in branching form [176–178].

10.1 Effects of Abiotic Stresses

Environmental factors affect the growth and physiology of turmeric plants and the plants show different responses to survive different kinds of stresses. At the reproductive stage, very low temperatures and water deficit conditions negatively affect the curcumin contents of turmeric [179]. Salt stress during vegetative growth decreases the osmotic potential and photosynthesis of turmeric plants, which decreases the quality and quantity of rhizomes [180].

10.2 Cultural Practices and Management

Turmeric is grown in tropical to subtropical climates [179]. The average temperature for proper growth ranges from 20 °C to 35 °C with an annual rainfall of 1500–2250 mm. Turmeric requires sandy loam to clay loam soil, but humus-rich soil with 4.5 and 7.5 pH is best for its growth. For rhizome sowing, ridges and beds are prepared with 2–3 times plowing followed by planking. The ridge-to-ridge or bed-to-bed distance is maintained at 2 feet while the crop is sown in May by keeping a seed-to-seed distance of 20 cm. Turmeric requires 20–25 irrigations while, in summer, the irrigation is applied at an interval of 7–10 days. Weeds are controlled at 60, 90, and 120 days after sowing [181]. Turmeric is an exhaustive crop and

Table 9 Chemical found in turmeric

Plant parts	Constituents	References
Essential oil	Diterpines, monoterpines (cineole, β-phellandrane, p-cymene, terpinolone), and sesquiterpenes (α-turmerone, β-turmerone, Ar-turmerone)	[185]
Leaves	Isoeugenol, α-terpinolene, isomaltol, beta-pinene, tumerone, γ-terpenine, eucalyptol, caryophyllene, and thymol	[186]
Aqueous extract of turmeric	Phenols, alkaloids, saponins, cardiac glycosides, tannins, and flavonoids	[187]
Rhizome	Saponins, carbohydrates, alkaloids, starch, proteins, tannins, amino acids, glycoside, flavonoids, and steroids	[188]

requires 150 kg of nitrogen, 60 kg of phosphorus, and 108 kg of potassium per hectare to get better rhizome yield [182]. Shoot borer, rhizome scale, lacewing bug, leaf beetles, and nematodes are important insects of turmeric [183] while rhizome rot and root rot are important diseases of rhizomes although leaf blotch and leaf spot also attack turmeric crops [184].

10.3 Chemical Constituents

The chemical constituents of turmeric is presented in Table 9.

10.4 Geographical Distribution

Turmeric is widely cultivated in Pakistan, Bangladesh, India, China, Indonesia, Malaysia, Haiti, Taiwan, the United Kingdom, the United States, and Japan, and is the key component of Ayurveda, Unani medicines, and traditional Chinese medicines [189]. The rhizome powder is commonly used in southern and southeastern tropical regions of Asia [190].

11 Therapeutic Uses of Medicinal Plants

The therapeutic uses of some medicinal plants are presented in Table 10.

12 Conclusion

This chapter describes the medicinal, aromatic, and flavoring properties of herbal plants and highlights the importance of their physiological ecology that helps to understand the therapeutic potential of these plants. The chapter also underscores the

Table 10 Therapeutic uses of some medicinal plants

Medicinal plants	Therapeutic application/diseases to be cured	References
Psyllium husk	Colon cancer, hypertension, ulcerative colitis, diabetes, and weight loss.	[191–193]
Black cumin	It has anticancer, antidiabetic, antioxidant, antimicrobial, and neuroprotective properties and is used to cure the following diseases: nasal ulcers, abscesses, back pain, eczema, orchitis, swollen joints, migraine, chronic headache, dizziness, chest congestion, dysmenorrhea, obesity, diabetes, paralysis, hemiplegia, and gastrointestinal problems such as stomach aches, dyspepsia, diarrhea, flatulence, and dysentery.	[194–198]
Stevia	Control blood glucose, cholesterol level, insulin production, cardiovascular functions, blood pressure, and inhibits the activity of bacteria and fungus.	[199–204]
Fennel	It has antitumor, cytoprotective, chemopreventive, hepatoprotective, estrogenic activities and hypoglycemic, and is used to cure nausea, kidney stones, and obesity menopausal problems and also improves digestion system of human body and prevent the infants from flatulence.	[205–208]
Bishop's weed/ carom seeds	It prevents heart diseases by regulating cholesterol levels and has phenolic compounds that quench the free radicals of oxygen in the human body.	[209–211]
Sweet basil	It has antifungal, antimicrobial, antiseptic, anti-inflammatory, and antiviral properties and helps to reduce migraines, mental fatigue, and insomnia. It is used to cure urinary tract, respiratory system, kidney and cardiovascular diseases, improves memory, and relaxes the neurological system.	[212–218]
Holy basil	It has antioxidative, analgesic, antibacterial, antiviral, antidiabetic, antifungal, anticancer, adaptogenic, cardioprotective, and hepatoprotective properties and is used to cure malignancies, diabetes, heart diseases, stomachaches, headaches, malaria, and inflammation.	[152, 219, 220]
Linseed	It is used to treat arthritis, cancer, and cardiovascular disorders. The alpha-linolenic acid contains omega-3 fatty acid (58%) that enhances the absorption of long-chain polyunsaturated fatty acids and is used in the treatments of heart, arthritis, inflammatory, cancer, and autoimmune diseases.	[221–223]
Turmeric	It has anticancer, antitoxic, antioxidant, anti-inflammatory, and antibacterial properties and is used as a brain and heart tonic to lower cholesterol levels. It is used against many disorders such as diabetic ulcers, anorexia, cough, biliary disorders, jaundice, hepatic infections, malaria, to treat tuberculosis glands in the neck, tumors, cancer, leucorrhea, liver, hemorrhoids, leukoderma, diabetes, and respiratory diseases. It is used to disinfect cuts and burns while its mixer with calcium hydroxide is a good home remedy to treat wounds swelling and to heal sprains. It purifies the blood, maintains the levels of triglycerides and cholesterol, helps to enhance the immune system, relieves joint pain, controls blood sugar, soothes irritated tissue, and cures allergies, and digestive and eye disorders.	[224–232]

importance of understanding the curative properties, botanical characteristics, and climatic requirements of medicinal plants. Cultivating medicinal plants successfully requires a deeper exploration of cultural practices specific to their growth. Several valuable medicinal plants, such as psyllium husk, black cumin or black seed, stevia, fennel, bishop's weed/carom seeds, sweet basil, holy basil, linseed, and turmeric, are grown worldwide and have multibillion-dollar market value. Despite their potential, medicinal plants have not been cultivated on a scale commensurate with their market value, primarily due to limited knowledge about their optimal growing conditions and poor adaptability to various environments. Authors, in this section, have also mentioned the botanical characteristics and climatic requirements of medicinal plants. To ensure successful cultivation and sustainable production, careful consideration must be given in the future to factors like soil selection, climatic conditions, and cropping strategies while preserving the safety and nutritional value of these plants.

Big Data Application in Herbal Medicine: The Need for a Consolidated Database

56

Christiana Eleojo Aruwa and Saheed Sabiu

Contents

Abstract

Advances in technology have created and will continue to create changes in traditional and herbal medicine development and applications. Globally, and on a daily and annual basis, an increasing amount of data is generated from the traditional and orthodox health care systems. While the term 'big data' is loosely used, the phrase seems to have stuck with many but with the possibility of evolving in the near future. 'Big data' connotes huge and complicated data sets that usually lack structure, are multidimensional, and exhibit heterogeneity. With the promise of data-driven knowledge and intelligent decision-making, big data projects are ongoing and massively being explored for candidate therapeutics identification and development using cheminformatics and bioinformatics as well as other advanced data analytic approaches. However, the process of engaging stakeholders to benefit from the information provided by big data remain a major issue, knowing well that such data sets have the capacity to be utilized as backup

for the support of medicines (herbal or otherwise) regulation. In the last decade, there has been an emergence of new data sets within the traditional medicine sector, with evolution of several institutional, national, and regional databases (DBs), providing new insights on phytochemicals, their efficacies, co-interactions, and mechanisms, and without much consolidation or unification. As such, repetitive data sets among databases have become the norm. This chapter presents how big data and big data analytics are being used and can be further explored in herbal medicine (HM) advancement, while advocating for consolidated HM databases. It also highlights the challenges that could be encountered in attempts to consolidate traditional medicines DBs, how they can be circumvented, and the many potential benefits of consolidated HM DBs. Likewise, other intertwined factors that are integral for advancing HM-based research, and drug discovery and development efforts for enhanced future health applications are discussed.

1 Introduction

Worldwide, the consciousness of research institutions, governments, regulatory agencies, and other health sector stakeholders has been heightened to possibilities of big data use in checking herbal medicines (HMs) impacts and efficacies. For example, in traditional Chinese medicine (TCM) or Japanese ‘kampo’, a plan has been evolved for data collation from millions of patients taking herbal medication. The prescription of ‘kampo’ medicines depend on herb mechanism and effectiveness, and patients’ experiences. Still, elucidation on mechanisms leading to various adverse reactions requires further scientific studies [1]. Agencies with roles linked to welfare and health care policy making have key functions in verifying herbal medicines effectiveness and side impacts. These roles cannot be extricated from care facilities, clinics, and hospitals cooperation since they provide the basic data from patient records which are uploaded into a big data (BD) server. Usually, data is first fed in as 'anonymous' prior to being statically analysed. The statistics generated then give insight into herb efficacy, best duration of use, frequency, and effective means of taking the medicines to cure or manage a disease with exclusion of adverse effects [2].

In other climes, the European Medicines Agency [1] in conjunction with Heads of Medicines Agencies (HMA) work to identify practical steps and state the regulatory frameworks for big data use to facilitate innovative developments and enhance public health among European Union (EU) countries. Medicines regulators can also use big data insights to measure the benefits and risks attributed to herbal medicines [1]. The foregoing is possible due to the large amount of data streaming on herbal medicine types being deposited in several medicine and health care-based databases. The compendium of data sets available from different platforms gives scientific backing for the effective use of herbal medicines without side effects. Thus, BD application in herbal medicine is also useful for health promotion and disease prevention [2].

Despite the potential benefits of big data application in herbal medicine, the health sector has failed to fully utilize data sets in varied databases to reduce disturbing disease trends and make health care more cost-effective. This is largely due to data inadequacy and/or unavailability, or availability of data in unusable forms. Again, health care and herbal medicine databases make data pooling and linking almost impossible. This has led to the emergence of many several and small institution based databased (DBs). While many health care practitioners take to ordering that several tests for effective treatment, the tests are usually ineffective and quite expensive. As a result, institutions like the University of Florida made available free and virtual public health data that is capable of efficiently analysing health-related information and fast identification in cases of chronic disease tracking. The 'Obamacare' initiative was also based on 'big data' utilization, much like other industry providers, for example, Humedica and Recombinant Data [3].

To date, not much is known about the science behind traditional medicines that make up a relevant aspect of global health care systems [4]. In clinical and everyday practices, the popularity of herbal preparations and medications continues to show a gradual increase, even to the developed Western world. The level of acceptance and impact of HMs is also encouraging. These drive HMs standardization using current pharmacological benchmarks. In the storage of knowledge and science behind trado-medical therapies, there have been the development of several databases (DBs) having varied focal points. The emergence of the traditional medicine DBs fast-tracked pharmaceutically oriented studies on products and metabolites from natural sources [5]. Natural products in HMs have continued to provide new insights and are key in current drug discovery research drives. Considering the information and data explosion especially from the life and molecular research fields, a new age of powerful networks and 'big data' was born. The building of sturdy DBs and networks is needed now more than ever to enhance the sharing of useful and interdisciplinary knowledge finding. As such, within the past decade, efforts have been put into verifying, restoring, digitalizing, and computerizing HMs documents in the form of DBs [6, 7]. However, each DB developer's outlook or focus may differ, but with a basic feature on plant metabolites and/or co-interaction details (plant/herb compound-biological activity-treatment links) and based on thousands of published research reports [8–10]. Many open access, subscription, and online DBs also target giving the user (both non-expert and expert) web-based experiences like compound to target protein interactions and molecular docking analyses [11, 12]. Unfortunately, there are also scenarios of recent DBs that came up sporadically which are no longer accessible, resulting in data loss on natural products of HM origin. In other case, consolidated or aggregator DBs are not enough to reduce redundancy and repetitive data set compilations [13].

Given these challenges with 'big data' use and access in health care systems, and sporadic emergence of single and localized platforms collating and providing information on bioactive herbal medications and phytochemicals efficacies and mechanisms, as well as herbal drugs' adverse effects, it has become important to expatiate on the need for consolidated databases to strengthen the science behind herbal medicines use and better guide future research on trado-medical applications.

2 Big Data Analytics, Platforms, and Herbal Medicine

Generally, data is passed through a cleansing, data joining, extraction of attributes, modelling, and prediction (grouping, categorizing, clustering, and so on), data presentation or visualization, interpretation, and reporting [14]. Analysis of health care-related big data can further be done with open-source platforms (MapReduce, Hadoop, etc.) [15]. For storage of distributed databases, Hadoop can be used. However, when merged with streams of continuously monitored health data, it is required that system adaptability and process optimization be improved using advanced data caching models and in-memory computation [16]. Within the health care industry, big data platforms like MapReduce carry out data processing and computation. Others such as Infogram and FusionCharts are good for data visualization, and Big Data Appliance and Pentaho Data Integration for data management. Large volumes of data sets with different structures have been handled with Oozie, Cassandra, PIG, Mahout, MapReduce, and HBase platforms, all of which are supported within the Hadoop distributed platform [17]. The Apache Spark Streaming, IBM InfoSphere, TIBCO Spotfire, and QlikView are some of the advanced tools used in analysis of big data [18]. Some data visualization packages include 'ggplot2' (open-source program for graphics mapping and creation) and 'igraph' (a library for graphs modelling and network analysis), which also exist within the R statistical programming language. The R software can be linked to many other visualization tools (RCytoscap for Cytoscape, RGraphViz for GraphViz, and RCircos for Circos). Data visualization using Tableau does not require programming skills. Circos is common with genome chromosomes visualization; GraphViz for laying out networks with large number of nodes and edges; and Cytoscape provides rich data presentation styles while saving layout of networks [19].

Furthermore, research has shown that there is a lack of study consensus on internally and externally sourced big data operation in health care systems. Again, big data is mostly analysed using natural language processing (NLP) tools which are based on Hadoop. Big data analytics is also applicable for optimizing clinical operations (decision support and cost reduction) but has a key drawback of its adoption being the lack of proof to back practical health care benefits. This challenge is closely linked to higher number of studies using qualitative strategies (describing possible gains) compared to quantitative approaches. In addition, it had been observed that more research reports were derived from developed than developing countries, hence the need to promote studies on health care BD analytics in developing or third world nations [20].

Data from trado-medical medicine applications require treatment and big data protection because they are vulnerable and sensitive, with immense potential to enhance disease diagnosis and prevention, and medical therapies [21]. Transforming unstructured data to usable forms that improve knowledge with benefits to patients comes with challenges [22]. Health care big data are presented as 'flat' and 'csv' files, tables, and so on, which emanate from internal and external sources [15]. Big data analysis and application in health care covers text mining (mostly unstructured data), machine learning and artificial intelligence (for predicting the unknown from learned known facts), and intelligent agent (for enhanced information flexibility, proactivity, and autonomy) technologies. Thus, big data analytics can be used in predicting outcomes for at risk individuals, identifying patients requiring preventive care, carrying out real-time analysis, provide public health services for at risk populations, conducting toxicity, side effects and trial design assessments, and accelerating acceptance of new therapies to target markets [23]. In order to attain a high level of precision in HM applications, particular accuracy is needed with respect to drug targets, disease markers and mechanism, among others [24].

3 An Overview of Herbal Medicine Databases

Some of the localized or institution-based, national, and international big data-based platforms providing free, limited, or subscribed access to processed and unprocessed information to guide research and decision-making as it relates to herbal medicines are discussed in the proceeding sections. We must, however, note that while each database has its unique qualities, main tables, central components, and structure, none is standardized for universal and unified global research. This may be attributed to none of the DBs allowing certified HM specialists scientists add their insights [25]. As such, the list presented here (Table 1) are in no way exhaustive.

1. *PubMed*: This platform is controlled and updated by the National Library of Medicine (NLM). It majorly targets life sciences, health care professionals, and physicians. It is the single largest and global biomedical database that allows the

inclusion of MeSH (Medical Subject Headings) terminologies like 'complementary therapies' and 'alternative medicine', with links to over 20 major headings [26].

2. *Micromedex*: This is database that is subscribed to and covers clinical procedures, dietary supplements, herbal medicines, herbal and dietary supplement co-interactions, and patient education. Subfield under acute care, regulatory compliance, chemical safety, pharmacology, and toxicology are also addressed. Although a subscribed DB, a study showed that health science librarians and educators need to strengthen and reiterate trainings, especially for students, on the proper utilization of drug information DBs like Micromedex [27].

3. *Duke's Phytochemical and Ethnobotanical Database*: On this platform, keyword searches can be performed on biological activity, plants, chemicals, and ethnobotanical fields and information derived may be pooled to other external databases. The platform is run by the Agricultural Research Service (ARS) of the US Department of Agriculture (USDA).
4. *Agricola*: This platform is used to find information on medicinal or herbal plants and is fed and driven by the National Agricultural Library (NAL).
5. *Complementary and Alternative Medicine (CAM)*: This platform is a rich resource for studies in complementary and alternative medicine (CAM). Other databases linked to CAM are the National Center for Complementary and Integrative Health (NCCIH), National Institutes of Health-Office of Dietary Supplement (NIH-ODS), and Natural Medicines Comprehensive Database (NMCD) [28]. The CAM DB is also a subset of PubMed linked to certain subfields within complementary and alternative medicine.
6. *Alternative Medicine – Health & Wellness Resource Centre*: This platform was launched from the Gale Encyclopaedia of Alternative Medicine.
7. *HerbMed or HerbMedPro*: This platform is a study-based resource providing information on the use of herbs as health remedies. It is a compendium of published processed data on toxicity, side effects, and contraindications on certain herbal medicines and provides links to research on medicinal plants, their preparation methods, efficacies, and mechanism of action. It is hosted by the American Botanical Council (ABC) and funded by the Alternative Medicine Foundation (AMF). The ABC provides scientifically backed information to promote effective and safe application of plants and herbal medicines. It also publishes the Expanded German Commission E monographs, HerbClip (reviews/summaries of seminal research), and HerbalGram journal. An article by Pollard [29] in HerbalGram emphasized the need for rational phytotherapy backed by product scientific evidence, especially for widely studied HM products derived for gingko (*Ginkgo biloba*), garlic, turmeric (*Curcuma longa*), and St. John's wort (*Hypericum perforatum*), among others.
8. *Review of Natural Products – Facts and Comparisons*: This provides several data subsets like facts on drug identifiers, off-label drugs, natural products review, and herbal co-interaction.
9. *Natural Medicines*: This database is a compilation done by physicians and pharmacists, and that requires subscription prior to access and use. It provides updated clinical data on herbal and natural medicines, as well as dietary supplements used by the Western nations.
10. *RXList-Alternatives*: This online TRUSTe certified drug index database contains herbal medicine groups from Chinese herbs and homeopathies, and the Western world. It also offers complete monographs and frequently asked questions (FAQs) sections. The major current and formidable competitors with this database include online platforms like webmd.com, singlecare.com, goodrx.com, and drugs.com. the latter online resources having over 30 million views quite early in the year 2023.

11. *Embase*: A pharmaceutical and biomedical database having more than 30 million indexed records, over 8000 peer-reviewed journal articles, and more than 2500 journals not accessible through MEDLINE and other international platforms. A study covering searches through Embase, MEDLINE, and other DBs showed that while the reported prevalence of herbal products and practices use was high, their use remained largely underestimated. As such, best practices covering submission of research reports on HM operational definitions like exclusion and inclusion criteria for treatments, practices or products, context of use, and detailed data on HMs exposure requirements were recommended. Likewise, the description of criteria used in coding the data, analytical strategies used, and publication of study survey questions used are needed [30].
12. *Examine*: This platform provides evidence-based herb/supplement, health, and nutrition health information, with coverage of study deep dives and summaries, trendy health topics, with detailed discussion of findings.
13. *Natural Medicines*: This platform reviews dietary and botanical supplements, and other CAM treatments, as well as provision of evidence tables which assess key research and baseline summaries of herbal medicines efficacies.
14. *Review of Aromatic and Medicinal Plants (RAMP)*: This platform provides reviews on aromatic and medicinal plants (RAMP). RAMP is an abstract database of globally published studies on wild and grown spice and herb species, medicinal plants, and essential oils. Coverage includes the biological activity, botany, cultivation, and use of these plants [31].
15. *VietHerb*: A database of plants and herbs used in Vietnamese traditional medicines and aimed at initiating data communication among other available disease, metabolites, geography, and plants ontologies in order to portray a concise description of each plant species. Information is provided on thousands of species and metabolites from hundreds of locations, and close to 10,000 oriental treatment efficacies. In addition, it provides links between herb morphology and species distribution, herb species and metabolite, and herbs and therapeutic impacts [32].
16. *Collection of Open Natural Products (COCONUT)*: This was believed to be the largest DB on natural metabolites. It is an online DB that is freely accessible and provides data on natural molecules or products in one single data set. Metabolites sparse annotations and structures are available for more than 350,000 non-redundant natural products [13]. It was based on the attempt to create an online resource that regroups identified natural metabolites into a single source location and simplify and facilitate natural products research and allow other downstream processing such as *in silico* screenings and related applications [33].
17. *The Pan-African Natural Products Library (p-ANAPL)*: This DB contains data and information on about 600 natural molecules of African plants' origin, especially those derived from the northern, southern, western, and central African territories. A study that screened NPs from this DB identified the compounds, boldine and ixoratannin A-2, as possible HIV-1 and hepatitis C virus (HCV) inhibitors. As such, these NPs could be incorporated in novel drug

formulation targeting the mitigation of these diseases [34]. The p-ANAPL library is believed to be the largest collection of NPs from African ethnomedicinal plants [35].

18. *Traditional Chinese Medicine (TCM) and linked DBs*: The presence of built-in algorithms and tools in this DB contributes greatly to enhancing its application in HM-related drug discovery, design, and development, and network pharmacology-based research studies. Network pharmacology effectively links HM NPs/compounds to protein or genetic disease targets, as well as underlying disease regulatory pathways, under high-throughput conditions. It is a relatively new and integral approach in drug development and mechanism studies. In addition, network pharmacology allows TCM and other HM-based mixtures or drugs synergy or combinations, target predictions, compatibility, and toxicological analyses. As such, it is a comprehensive, rational, and powerful tool for studies in HM [36]. Databases for HM-network pharmacology studies include the Traditional Chinese Integrated Medicine (TCMID) [37], Traditional Chinese Medicine Systems Pharmacology (TCMSP) [38], ChEMBL (https://www.ebi.ac.uk/chembl/) [39], TCM database@Taiwan [8, 40], TCM-Mesh [41], Herbal Ingredients' Targets (HIT) [42], PubChem [43], and STITCH (to find association among phenotypic, cellular, and molecular data) [44]. Among the databases to study interactions between proteins or gene targets, IntAct (a molecular interaction DB; https://www.ebi.ac.uk/intact/home) [45], human protein-protein interaction DB (HAPPI; http://discovery.informatics.uab.edu/HAPPI) [46], Human Protein Reference (HPRD; https://www.hprd.org/) [47], Molecular INTeraction DB (MINT; https://mint.bio.uniroma2.it/) [48], STRING (for protein-protein interaction networks functional enrichment analysis; https://string-db.org/) [49], and Reactome [50] have been used. On the other hand, Genetic Association DB (GAD; https://geneticassociationdb.nih.gov/) [51] and Online Mendelian Inheritance in Man (OMIM; https://www.omim.org/) [52] were useful to link various gene targets to diseases.
19. *Ethiopian Traditional Medicine database (ETM-DB)*: The search for novel drugs and drug designs has pushed scientist back to nature for answers. The collation of valuable data and information on the resplendent natural resources found globally has led to the development of trado-medical DBs like the ETM-DB. In order to expand on drug discovery strategies based on natural NPs, the ETM-DB was floated as the largest, open access, structured, online database synergizing indigenous HM knowledge from over 80 ethnic groups. Moreover, close to 80% of the population access herbal medicines for their primary health care needs. Within this user-friendly DB web interface, the search menu provides and array of topics or entities (target genes, species phenotypes, compound, prescription, and herb) to choose from. It also allows users to search for relationships between and among entities within it and other natural products DBs like TCM, Natural Database for Africa (NDA), and South African Natural Compound (SANCDB). Such DB consolidation efforts were aimed at fast-tracking the drug development and discovery processes based on NPs of Ethiopian origin. The DB website (http://biosoft.kaist.ac.kr/etm)

provides essential raw and processed data on NP chemistry and composition, including associated human protein or gene targets [53].

20. *Natural Database for Africa (NDA)*: This DB was emanated from an initial effort to consolidate HM and NPs information from East Africa and Ethiopia. Interestingly, the NDA covers data on about 7000 African plants, but majorly of Ethiopian origin, and the rest from African nations along its borders. Information such as plant species local or traditional, and botanical names, and their herbal applications can be found within the NDA. This DB is, however, limited for drug discovery focused studies, because it does not provide additional information such as herbal medicines components and target genes [54].
21. *Universal Natural Product (UNaProd)*: This is DB derived from Iranian traditional medicines (ITMs) and consists of an array of therapeutic HMs. UNaProd was initially built on Makhzan al-Advieh (a medical encyclopaedia covering simple drugs) using manual and text mining and had the widest coverage of ITM monographs. UNaProd is an advancement of this and allows access to close to 3000 ITM-based monographs including mineral, herbal, and animal compounds with over 15 different features. It was created as baseline upon which to build a systems pharmacology platform capable of correlating disease, drug, and target attributes. Hyperlinks exist within UNaProd connecting to Collective Molecular Activities of Useful Plants (CMAUP) (National University of Singapore-based) and other DBs [55]. CMAUP covers over 2500 medicinal plants, as well as data on garden, agricultural, and food plant species [56].
22. *Other herbal metabolites and plants databases*: These include the BDTOI (a bilingual platform of Indonesian origin and catering to Indonesian therapeutic plants with metabolites referenced with KNApSAcK and PubChem); CVDHD (a cardiovascular disease herbal database providing annotated structures with docking score and thousands of targets with optimized 3D structures); ChemieBase (a Thailand database for herbal plants' metabolites); Chinese Herbal Medicine Database (CHMD); Dictionary of Natural Products (DNP) (a sub-database of CHEMnet-BASE that allows concurrent integrated search); HIT (a curated and comprehensive database offering data on herbal metabolites interaction with target proteins); NPASS (database for natural products, their biological targets and bioactivities) [57]; HerDing (recommends herbs to treat infections using information from bioactive molecules and genes through text mining and integration with many other databases); IMPPAT (manually curated database of Indian medicinal plants metabolites) [58]; Reaxys (a commercial, Elsevier-owned database, offering a vast metabolites library from data generated from years of scientific findings); TradiMed (a commercial platform that merges Korean and Chinese traditional medicines knowledge and insights to facilitate modern drug discovery from HMs); and TCM Database@Taiwan and Super Natural II, among a vast array of other databases [5, 59]. Others include the South African Natural Compound (SANCDB) [60], Yet another Traditional Chinese Medicine (YaTCM) databases [61], KUIHerb [62, 63], MedHerb and HerbalHall [64], and InPACdb [65]. Additional examples of African traditional

medicine database include the Botanica Ethiopia, PROTAbase, PlantZAfrica, PRELUDE, and Francophone, among others [60, 66–69].

4 Initiating Databases Consolidation, Challenges, and Benefits

Integration of data or data consolidation (DC) implies collation, combination, and storage of data within a single harmonized one-point access space. Such consolidated platforms may facilitate the derivation of insightful information from inherent raw or processed data by users for enhanced decision-making. Database consolidation also helps in trends discovery and data sources streamlining. Achieving this may typically involve technological layers such as the data source, a data pipeline for its extraction, loading, and transformation, and the data warehouse. A data pipeline may be built through hand coding and automated cloud-based tools. In hand coding, data engineers write scripts to integrate data from already known sources. Hand coding is a laborious task that is best tailored to fewer data sources or when the data store or source is not linked to other tools. On the other and, the use of cloud-based tools to automate data pipelines fast-track the process of data consolidation. Cloud-based platforms tools are periodically evaluated, maintained, and updated by the provider. Some data consolidation practices include checking compatibility of in-source data types and target, maintenance of data and processed output copies for improved traceability, compliance checks, accountability, and surveillance. In addition, standardizing data character set conversions enhances data consolidation for more dependable results after data processing [70].

Common impediments to data consolidation include those attributed to the demerits of hand coding. Here, new levels of code may often be required to be written, managed, and processed with incorporation of new online data sources, thus lengthening the process of consolidation. Again, both potential and real security issues plague DC. Data breaches can occur prior to and after DC. Data can also be deleted, corrupted, or compromised during backup development. The problems with data exfiltration (data copying, transfer, or retrieval without authority to access it) from DB servers or computers also exists. Inconsistency of data types stored in different locations, missing data, and similar or duplicate data may also be found across several sources or databases, making consolidation a herculean task [70].

Despite the aforementioned and highlighted challenges, the benefits of DC cannot be overemphasized. Databases consolidation ensure the decreased complexity, enhanced data infrastructure, and greater control of the data environment. Importantly, DC minimizes perceived number of DB issues, optimizes DB availability and space, performance, and systems security. As essential building blocks, DBs enable the storage of accessible and organized formats for smooth functioning in HM research. Nonetheless, keeping up with the pace of change and the generation of spurious, unverified data sources, the best time is now to welcome a consolidated future for HM research. Adopting DC could greatly reduce cyberattack risk through easily enforceable polices covering fewer DB platforms, scaling back of data access points by reduced systems vulnerabilities, and improved monitoring and reaction to perceived and real threats. Again, more modern consolidated systems tend to have a generally reduced risk of intrusion through regular hard and software updates. The use of consolidated DBs also serve to reduce cost and increase platforms efficiency, compared to many separated DBs with limited data sets and scale. In consolidating DBs into optimized systems, operational cost is reduced due to decreased maintenance and hardware, and limited number of DB licenses required. A modern and standardized DB may also offer better strategic data architecture and access restriction tools such that one can only access data they require for particular tasks. A disjointed data and information infrastructure makes it hard to derive a general overview of the desired data set. Furthermore, DB consolidation ensures data protection and streamlined recovery through use of a robust disaster recovery approach and backup systems [71].

More specifically, other gains from HM DBs consolidation include a greater base on which to build multi-strata policies for HMs use and its integration into health care systems alongside World Health Organization (WHO) guidelines. Database consolidation facilitates the establishment of regulations for HM practices, products quality, and safety controls, and increases awareness on HMs efficacy and safe treatment regimens among products end users and general public. In the same vein, it ensures the sustainability of ethnomedicinal plants through their conservation and cultivation while constituting an integral scientific evidence base on trado-medicals quality, safety, and efficacy [72, 73]. In order to solidify consolidation efforts, more collaborations between countries and international regulatory agencies like the WHO and USDA could contribute to encouraging HMs valorization, cost effectiveness, and availability [74, 75].

5 Emphasizing and Ensuring the Need for HM DBs Consolidation

5.1 Herbal Medicine Products and HM-Based Studies: Case Scenarios and Approaches

This section briefly zooms in on some research efforts on herbal medicinal products (HMPs) and related new findings from HM-based studies. This is in efforts to entrench the need for update of HMs new findings, information, and DB consolidation, and which could be spread across board to analytical techniques and assay methods to bridge widening study gaps. Some research, such as that conducted at the University of Oulu, focused on the toxicological and pharmacokinetic attributes of developed HMPs to strengthen potential market base and give scientific proof to claimed therapeutic value. The application of chemogenomic tools gives key predictions into potential toxic impact as shown for some Ayurvedic and TCM products [76]. Nonetheless, validation of the *in silico* predictions remains necessary through actual clinical and experimental research. Here, 'omic' tools prove to be indispensable to delineate and assess different mechanisms and toxicities [77]. Application of existing and modified *in vitro* interaction, metabolism, and transport assay protocols have also sufficed for HMPs, as they have for orthodox medicines [78–80]. While the multi-component structure of HMs is expected to evince multi-level dynamic and kinetic interactions, the therapeutic responses of herbal products may also be predicted to a limited extent based on their individual components [81].

In other research efforts, underutilized plants are scientifically valorized to enhance their industrial applications. For example, new molecules identified in prickly *Opuntia ficus-indica* like polyhydroxypregnane glycoside, neohancoside C, and isovitexin 7-O-xyloside-2″-O-glucoside from cladodes [82], and pinellic acid from fruit peel and pulp [83] contribute to the reported pharmacological properties (antibacterial and antioxidant) of the extracts. Yet, these molecules or extracts have not been subjected to molecular biological techniques to gain further insights on potential therapeutic functions. Another study on a south American plant species, *Baccharis dracunculifolia* in the family Asteraceae, has shown good anti-inflammatory action for use in the treatment of skin diseases [84–86]. As such, the commercial and economic value of this plant has shown steady increase in past years since it is also a natural source of Brazilian green propolis [87]. The plant's leaf extract has also shown the ability to modulate immune system responses [88, 89] and protect the liver [90], as well as have antimicrobial [91] and analgesic properties [85]. These features were linked to the extract's flavonoid (e.g., isosakuranetin) and phenolic acid (mostly artepillin C) contents [88]. In the root extract, more recent results identified the presence of monoterpenes, triterpenes, and fatty acid derivatives, and a major plant-specific compound reported for the first time as baccharis oxide. Both baccharis oxide and extract showed good topical anti-inflammatory activity, thus supporting its use in skin ailments like dermatitis, psoriasis, and other skin inflammatory diseases. The study, however, noted that peculiar action mechanisms and assessment of toxicity and safety levels of both the new compound and extract required additional exploration [87].

In providing added examples, in case of chronic neurodegenerative disorders, neurological inflammation is key to the disease progression, and the peripheral organs, brain, neurons, and the elderly are mostly adversely affected [92, 93]. The disease also has negative impacts on health care systems, communities, families, and communities [93]. Furthermore, curative or preventative therapy options are not available as a result of dearth of insight on its complicated pathophysiology and causal factors [94–96]. In order to make headway, the multi-target and component system action of HMPs could be practical in addressing the complicated neuroinflammatory mechanisms and pathology. A study analysed the synergistic effect of HM formulas in diminishing neuroinflammation by applying molecular docking, network pharmacology, and experimental analyses. Results showed that combinations of 6-shogaol and baicalein, and 6-shogaol and andrographolide, at 50% inhibitory concentrations (IC) of 3.28 and 2.85 g/mL synergistically slowed lipopolysaccharides-induced nitric oxide (NO) generation in immune cells of the brain. The key genetic pathways put forward for the action of the three identified molecules are the mitogen-activated protein kinase 8 (MAPK8) and 14 (MAPK14) and nitric oxide synthase 3 (NOS3) pathways, using network pharmacology analysis. On the other hand, docking analysis showed significant binding affinities of the three molecules to respective protein targets. Studies like these which utilize an array of *in silico*, *in vitro*, and experimental tools, platforms, and information from HM DBs show a practical strategy in new herbal molecules and product formulations development. At the same time, they give scientific baselines and novel understanding into synergistic combinations against neuroinflammation. Such study designs, workflow, and tools could be extended to other disease research [97].

5.2 Need for Consolidated Databases in Herbal Medicine

Given the sporadic emergence of HM databases, it is also important to discuss the need for their consolidation to strengthen herbal health care access and delivery systems in the face of 'big data' availability. Health care BD drawbacks include large data volume, dimension, and format variability, data value, presence of poor quality or 'noisy' data (trustworthiness or veracity issues) (Fig. 1), strengthening and processing isolated (silo) data sets from individual health care institutions. Other drawbacks include classification and analysis of semi-structured or unstructured data, processing and compiling continuous data streams, that is, data velocity (rate at which data is generated, collated, and analysed), intensive computational needs for analysis of genomic data, and problems with big data visualization. Problems with cybersecurity, data privacy (Fig. 1), ownership, and governance constitute other

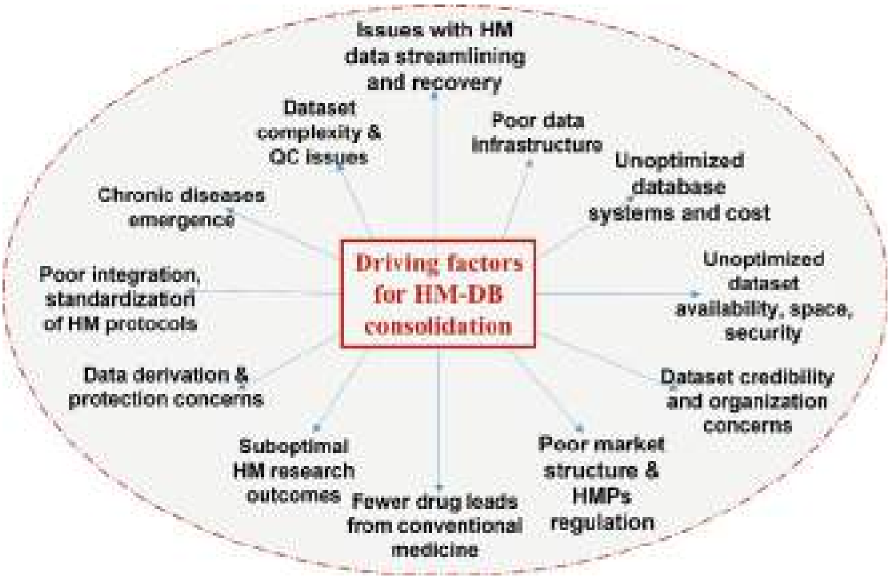

Fig. 1 An overview of factors that drive the need for herbal medicine database consolidation. *QC* quality control, *HM* herbal medicine, *HMPs* herbal medicinal products, *HM-DB* herbal medicine database

valid challenges [13, 50, 98–100]. In line with these challenges, even when a patient's privacy is protected, quite several health care practitioners are unwilling to share data due to market competition. As such, maintaining a balance between patient confidentiality and data integrity (Fig. 1) remains a daunting task. Again, the number of available open access databases or resources, the integration of useful and structured data, and their standardization make up present challenges [101].

Privacy and cybersecurity problems include unauthorized access or hacking, data sets combination without analysis resulting in future breaches in privacy, merging of varied data sets in a way that contravenes privacy laws, and data capturing which is bereft of human activity that raise ethical issues. Usually, outcomes of health care data analysis are traced back to the patient to aid in disease diagnosis, prognosis, and decision-making on most effective therapy regime needed. Thus, herbal medicine data is not fully 'anonymous', and some form of false, complex anonymity protocol is created to ensure some level of 'k-anonymity' which is acceptable on a legal and ethical bases. Yet, if big data subsets are re-associated or merged with other data, 'k-anonymity' reduces greatly with increased risk to data privacy. Hence, adaptable and advanced algorithms are needed which circumvent scenarios where decreased k-anonymity fall below acceptable levels [102].

Furthermore, in many African nations, despite the use of Western medicines, over 60% of Africans still patronize traditional HMs as a complementary medical source to ameliorate disease effects [103, 104]. However, it has been reported that only partial knowledge of herbal medicine is available such that hair-brained herbal practitioners' cash in on the situation by providing contentious medical care with prepared medicines that do not perform as expected and portend several dangers to health of herbal medicine clients [105]. Again, poor communication exists among herbal care practitioners, and this is aggravated by little or documentation of their knowledge leading to underdeveloped knowledge systems or knowledge loss [103]. This herbal medicine knowledge system is inappropriate, inefficient, difficult to transfer and access, and tacit, particularly for durability in knowledge use and preservation [106]. This explains why trado-medical knowledge is lost over time. In certain cases, herbal knowledge misuse, abuse, misappropriation, and misinformation have also been reported [105]. This is a cause for concern since improper documentation of herbal medical practices that involve methods of preparation, ingredients selection, and mode of administration have led to a lack of trust in herbal medicines effectiveness, safety, and quality [107]. Hence, the importance of HMs knowledge preservation cannot be overlooked, because it strategically affects the levels of competitive advantage, sustenance, and growth that HMs have in various institutions, environments, and on persons [108]. As a result, mitigating strategies are required to potentially rectify the drawbacks (Fig. 1) facing HM practices with a view to restoring prevailing circumstances [104].

Considering the above challenges, a recent study proposed an approach for data capture, storage, compilation, and semantic search of African herbal medicines based on a consolidated hybrid (incorporating ontology and machine learning tools) knowledge-based model for enhanced data retrieval and preservation. The strategy allows multi-word searches and functions as a useful resource for extraction of herbal medicines knowledge from a real-world application context [109]. In addition, it is essential that herbal medicines BD should emanate from actual patient data to achieve beneficial health knowledge. Big data application in herbal medicine cannot be fully optimized if it does not translate to enhanced patient health care. Although a challenging process, it is clear that a continuous co-interaction between small (individual) and big (population) data, medical care, and clinical studies cannot be overemphasized. In predictive modelling applications, the combination of varied data types (clinical, -omics, molecular, physiology, and imaging) should also be the rule of thumb [110].

Generally, health care big data challenges are linked with large data volume, data formats, data streaming, reliability and veracity, data visualization, privacy, and cybersecurity, and so on (Fig. 1). In addition, the main problems with big data and their analysis lie particularly in segmented data consolidation and processing, mining of data from distributed and heterogeneous health databases, cross-border health care management (different cultures, languages, and countries), and discrepancies between 'individual' and big 'population' data. Therefore, a continuously streamlined co-interaction between small and big data could be circumvented by through herbal medicine databases consolidation. This would further portray a more global, unified, and synchronized front, provide added scientific backing for herbal medicines-related research, while strengthening the veracity platforms, tools, and databases and minimizing the core concerns with big data use and application. The emergence of consolidated herbal medicine databases will further encourage the exploration of herbs or plant bioactive constituents in herbal drug formulations to better tackle specific infections and comprehend and predict treatment impacts based on metabolite profiles and a scientific perspective. Some thought also needs to put into making consolidated HMs database designs user-friendly with interactive elements that facilitate easy information retrieval [111].

Furthermore, of the over 120 DBs on HM metabolites and products that are cited in literature, less than half can be freely accessed. Yet, major content overlap exists in these DBs, where about 40 of them share data sets on half the number of metabolites with at least one other data set. Some consolidators or aggregator DBs like the SuperNatural II and ZINC catalogue for natural compounds exist. However, they do not suffice to efficiently synchronize all possible and available data and information on known natural metabolites. These aggregators also do not allow submissions of newly discovered compounds. Hence, there is a major need for consolidation of organized and globally recognized DBs for natural compounds linked to HMs, to facilitate the easy addition or submission of novel metabolites, as seen with the UniProt proteins DB [13].

In further analysis to drive home the need for HM DBs consolidation, a transient look at HM-related boards such as traditional and complementary medicine (T&CM) methods, new HM findings, and protocols such as herbal medicinal products (HMPs) development are briefly discussed. Consolidation of these HM-related aspects could further strengthen the quality of consolidated HM DBs. Herbal medicinal products are the derivatives of increasing HM studies which are increasingly published as articles in many Western journals primarily focused on T&CM.

These HM-based articles cover subjects ranging from products interactions and efficacy to safety concerns with review papers never failing to highlight the dearth of HM quality-based research. This concern remains valid since clinical trials aimed at elucidating on any drug's efficacy, toxicity, and safety eventually show the HMP's therapeutic use/application. Again, such trials give scientific backing and proof for the use of HMs and ensure HMP quality control, standardization, authenticity, provided good practices (GPs) in T&CM are applied [112]. Within these practices, care must be taken to scientifically define important controls and evaluated outcomes. This cannot be overemphasized since HMPs are usually a complex mix of herbal extracts. As such, study strategies aiming to expatiate on HMPs mechanisms of action, especially with 'omic' and network pharmacology technologies, are needed. The impacts of these tools in revolutionizing HM-based research through emphasis placed on disease gene or protein targets and their interaction with compounds and compounded mixtures, as they have done with conventional orthodox drugs, are immense [81].

In addition, new approaches have become integral in HM studies because chronic diseases continue to emerge and continue to worsen death and morbidity trends in both the developed and developing climates. Whether communicable or non-communicable, these chronic disorders are associated with many mechanisms, underlying molecular networks and pathways etiological factors [113, 114]. Although new conventional orthodox medicines have been slowly developed within the last decade, there has been little or no improvement in drug therapeutic outcomes in terms of associated drug risks versus benefits analysis. This may be closely linked to the myopic research focus on particular disease to particular drug paradigm, or one compound to target outlook with emphasis on molecular and biological techniques and strategies [115]. Molecular biology (MB) tools are key in elucidating possible medicine targets with selection of potent therapeutic molecules. However, these MB results have not amounted to feasible drug development to cater to clinical realities. Consequently, a much better go-to plan would be to engage a range of targets at a time with several mechanisms, as opposed to one target. Still, a balanced approach has to be employed in line with good practise in T&CM. HMs could be the answer to challenging multiple disease targets at once and aid in reducing the search gap for promising drug leads, assays, and analytical protocols development [112]. The scientific validation of HMPs using advanced analytical tools could further aid in redesigning the HMs market [116–118]. It can also help change the 'untrusting' viewpoints of the Western, developed societies and thier HM regulators. This is important since the Western world mostly believes that HMs research lack quality, are outdated, sporadic, and uncoordinated when compared with conventional medicines [119, 120]. As such, ensuring the proper coordination of the varied aspects of HM-based studies as well as its update and consolidation of its related databases are key to advancing science behind T&CM. Also, as part of HMs DBs consolidation, policies outlining the steps to take in verifying and depositing new NPs or herbal compounds and other novel findings and information from plant species should also be explicitly described at local, national, regional, and international levels.

6 Conclusions

Over time, data generation has been reported to go through a passive data input stage, an active phase where users input data directly via the internet or web, and the automatic phase. While the process of data generation cannot be totally reversed, the discovery of health care big data features, improving therapeutic efficacies, and promoting the benefits of big data in health care systems constitute valid future outlooks. The concept of 'big data' is here to stay and will continue to give new insights to herbal medicine applications. Big data cannot be extricated from herbal and integrated medicine advancements and is key to evolving to evidence-based medicine from experience-based medicine. The introduction of computational, bioinformatics, and algorithm-based platforms has further aided in big data analysis, categorization, and organization [121]. Regarding natural molecules efficiency and assessment, novel advancements in HM safety and mechanism attributes are still needed to ensure gradual attainment of wholesome data quality, consistency, and control [122]. Most importantly, the projected impact of and need for increase in consolidated DBs cannot be overemphasized in ensuring the availability of credible, non-repetitive, and up-to-date data or information on both existing and new HMs and natural metabolites. Overall, the benefits of HM DBs consolidation outweigh the disadvantages. As such, the challenges to herbal medicine databases consolidation could be overcome by collaborative efforts from all relevant industry stakeholder. The near future gains in advancing the course of HM-based studies, especially as regards drug discovery and development to improve health care therapeutic outcomes and applications, should not be undermined.

Challenges in the Storage of Herbal Medicine Products and Strategies for Sustainable Management

57

Priyanka Devi and Prasann Kumar

Contents

Abstract

Medicinal plants, the world's richest source of herbal products, are rapidly disappearing as global demand for these resources surges. This chapter aims to serve as a reliable guide for the conservation and responsible utilization of medicinal plants by examining current and future global trends, developments,

P. Devi · P. Kumar (✉)
Department of Agronomy, School of Agriculture, Lovely Professional University, Phagwara, India

S. C. Izah et al. (eds.), *Herbal Medicine Phytochemistry*, Reference Series in Phytochemistry, https://doi.org/10.1007/978-3-031-43199-9_37

and preservation strategies. The sustainable use of these resources, incorporating good agricultural practices, conservation methods like in situ and ex situ conservation, and cultivation practices, is deemed essential for their long-term viability. To enhance the yield and potency of therapeutic plants, we propose adopting biotechnological methods, such as tissue culture, micropropagation, synthetic seed technology, and molecular marker-based techniques. Additionally, it is crucial to ensure the safe and effective use of Ayurvedic herbal medicines through proper storage and handling of plants intended for various Ayurvedic dosage forms. This involves establishing sound storage facilities, raw herb packaging, adherence to API format for herb testing, microbial elimination from herbs, sterilization processes, and best practices for spice storage. Regulating the storage, packaging, and processing of raw herbs for various Ayurvedic herbal medicines is pivotal to enhance the evaluation of quality, safety, and effectiveness in the realm of medicinal plants. Standardizing these practices will produce safer, more effective, and higher-quality herbal products, potentially expediting the global adoption of the Indian medical system.

1 Introduction

Traditional herbal remedies predate all other forms of medical treatment used by humans. Because of this, herbal medicine is an integral part of many different types of conventional medical practice all over the globe [78]. The World Health Organization (WHO) reports that roughly 74% of the 119 plant-derived prescription medications used today have been used for centuries in traditional treatment [7]. Today, 90% of the global population still uses unprocessed preparations and uncooked plants for medical purposes. Concerns about natural medications' quality, effectiveness, and safety have been raised. In light of WHO's efforts to evaluate medical plants' quality, safety, and efficacy, the botanicals used in the different Ayurvedic Dosage Forms must be appropriately stored, packaged, and handled. The therapeutic effectiveness of a given medicinal plant varies as its plant material does in terms of the proportion of active compound, which in turn changes according to the location of collection, the time of collection, the environmental variables, and the surrounding of its growth [15, 26, 27, 33–36]. Insects, bugs, fungi, microorganisms, pesticides, and other animal matter (including animal excreta) should not be present in vegetable medicines used as such or in composition. These could be free of any off-putting odors, colors, sliminess, mold, or other signs of decay and within the legal and recommended limits for lead, arsenic, and heavy metals essential components for standards according to the Ayurvedic Pharmacopoeia of India, including quantitative tests such as total ash, water-soluble ash, acid insoluble ash, alcohol-soluble extractive, ether-soluble extractive, moisture content, volatile oil content, and assay. The quality control measures taken during the production of herbal medicine, as well as the storing, packing, and processing of the raw materials, the shelf life of the finished product, the presence or absence of preservatives, herbicide residue, and other factors, all contribute to the product's overall safety and effectiveness. Because of these factors, it is clear that several in-depth studies are needed to determine whether or not Ayurvedic natural plants are safe and effective before they can be used in treatment. The plants' freshness and viability are directly impacted by their proximity to light, air, and microorganisms. Since the unprocessed plants are oxidized by air and decomposed by light, their security decreases as time passes. The appropriate packing substance for raw plants must be researched and chosen to ensure product compatibility and the preservation of qualities. It is possible to keep raw plant medicines in a way that prevents them from getting contaminated or going bad. The active component in fresh plants can be preserved for an extended time if proper precautions are taken to protect them from the impacts of air, wetness, heat, and light. Changes in color, flavor, taste, and physical structure indicate the degradation of therapeutic components of plants. Proper storing techniques guarantee the safety and effectiveness of completed plant goods by preventing contamination and degradation. Raw plants can be cleansed, rinsed to eliminate organic material and other impurities, sanitized to avoid infection, and dried correctly before storing. Ayurvedic Pharmacopoeia of India guidelines can also be used to evaluate the product's identification, purity, potency, boundaries of heavy metals, microbiological burden, herbicide residue, and aflatoxins [15].

The use of natural remedies has skyrocketed all over the world. The Secretariat of the Convention on Biological Diversity reports that in 2000, the worldwide market for plant remedies generated an estimated \$60 billion [76]. The worldwide market for plant supplements was valued at around US \$83 billion in 2008, with annual development rates between 3% and 12%. Unfortunately, there are still significant dangers involved with natural remedies [19]. Most adverse outcomes can be traced back to subpar manufacturing standards, some of which can be traced back to tainted plant ingredients. Herbal medicine, as the World Health Organization (WHO) describes, is any substance or product produced from vegetation used to treat or prevent human disease. There are three types of herbal medicines. There are three types of herbal products: (1) raw herbal materials, (2) traditional herbal products, and (3) controlled herbal products. Raw herbal materials include powdered or segmented botanicals, while processed herbal materials include tablets, capsules, and decoctions (formulations containing standardized extracts or purified substances).

Nature has been generous to humans since the beginning of time, meeting our requirements regarding food, housing, medication, and other resources [11]. The decline in ecological resilience and the accompanying increase in susceptibility to shocks and disruptions directly result from human activities such as removing wildlife areas and felling trees and vegetation for their wood. The state of human health is inextricably linked to the state of the world in which we find ourselves; for people to be healthy, they require both environmentally conducive settings and a well-functioning healthcare system that offers eco-friendly, bio-friendly, cost-effective, and reasonably secure therapies [57]. Synthetic medicines have vastly aided in treating or avoiding several acute/chronic/life-threatening illnesses, thanks to humanity's desire and contemporary technical and scientific breakthroughs creating success in finding synthetic medicines. However, contemporary society faces grave danger from the harmful adverse effects of overuse and extended use of these medications. Alarming changes in the structure and function of the environment have occurred recently due to increases in pollution, bad habits, tension, and loss of plant variety. Many people in the modern era prefer to take preventative measures and opt for treatments that pose less risk, leading to the popularity of therapeutic plants in conventional medicine. Herbal products are becoming increasingly prevalent worldwide because of the widespread belief that they are safer than conventional pharmaceuticals because they contain fewer toxic ingredients, have fewer side effects, and work better with the body's natural ecosystem than synthetic chemicals [14, 61]. Traditional medical methods often include using healing herbs as an essential component. Herbal remedies have been used and recorded in the medical practices of ancient India, China, Egypt, Greece, and Rome for at least the past 5000 years, according to the earliest documents available. America, the Arabian Peninsula, and Japan are just a few places where traditional plant therapy has been used since primordial times. The Rigveda, the Ayurveda, the Charak Samhita, and the Sushruta Samhita are all transcriptions of ancient Indian conventional medical practices. The indigenous healthcare system also heavily relies on folk (tribe) remedies. In early times, India was recognized as a hub for collecting and preserving valuable medical plants. Many beneficial and pleasant-smelling flora can be found in

India's woods [12]. Studying medical plants, isolating their valuable components, and conducting chemical screening can lead to discovering novel, clinically active medicines. Codified systems like Ayurveda, Siddha, and Unani practices, as well as traditional medicine of India, are believed to include more than 6000 higher plant species [70]. India is poised for a botanical renaissance thanks to its abundance of valuable plants and ability to satisfy the rising global demand for therapeutic plants. Medicinal plants can be crucial to the expansion and improvement of the economy, and not just in the healthcare sector. Due to the biodiversity loss, many important therapeutic plants are in danger of disappearing [4]. India has a significant opportunity to play a leading role in ensuring the continued survival of plant species and the responsible application of those species' genetic resources in the service of human health and economic prosperity.

2 Plants Used for Medical Purposes for Healthcare Systems

Throughout history, plants have consistently served as a valuable resource for the discovery of new therapeutic compounds, and this trend remains robust, as such they have been variously studied for their pharmacological properties. Due to the ubiquitous nature of microbes, plant with antimicrobial potentials are often studied [28–32, 41–43]. While only a fraction, approximately 5–15%, of the total 250,000 higher plant species have been extensively characterized to date; there's a growing anticipation that many plants hold untapped potential for novel bioactive compounds. This vast reservoir of plant-derived resources has only begun to be tapped into [11].

Herbal remedies and other plant-based products are integral to the healthcare industry, especially in remote and less-developed regions. Contemporary medicine has harnessed various medicinal plant-derived compounds such as reserpine, deserpidine, vincristine, morphine, etoposide, teniposide, nabilone, z-guggulsterone, lectinan, artemisinin, and ginkgolides [49, 71]. These natural products often serve as foundational elements for research in the fields of biology and pharmacology, often leading to the development of synthetic medicines. An estimated 75% of globally used medicines find their origins in traditional remedies [71]. In India, nearly 70% of contemporary medications are derived from natural sources, and many synthetic counterparts have evolved from prototype compounds obtained from plants, with these natural resources forming the basis for most of these synthetic equivalents. This percentage is projected to increase in the future [61].

Despite the wealth of plant species, only a small fraction has undergone comprehensive chemical and pharmacological research, approximately 6% of all identified species. The natural product industry is experiencing remarkable growth, driven by rising demand for products related to weight management and skin health [53]. Within the botanical product market, conditions associated with the cardiovascular system claim a 27% market share, respiratory system-related diseases hold 15.3%, intestinal disorders represent 14.5%, hypnotics and sedatives make up 9.6%, while other conditions collectively account for approximately 13% of the market.

Compared to the lengthy and expensive process of discovering, researching, and developing synthetic medicines, natural medicines have demonstrated the potential to require significantly less time and financial investment [72].

The undesired and, at times, the unpredictability of side effects brought on by the use of synthetic drugs is the primary disadvantage associated with this practice. These unwanted effects can potentially be more harmful than the conditions that synthetic drugs are purported to address. Natural medications are generally more secure and have fewer adverse side effects than synthetic ones. Manufactured drugs, even though some of the drugs derived from plants, such as vincristine, also have some potentially life-threatening side effects. Compared to synthetic medicine, herbal medicine is predicated on the premise that it contains natural substances that can support health and alleviate illness. Keeping the body disease-free and healthy has also been shown to be possible through the consumption of plant-based foods and the use of botanical remedies as nutritional supplements [58, 59]. According to the World Health Organization, most people in underdeveloped countries across Asia and Africa rely on botanical medication as their primary healthcare method. In recent years, there has been a significant increase in industrialized countries using conventional or supplementary alternative treatment. Dietary supplements derived from plant materials are currently becoming increasingly popular. Because of the steep rise in the consumption of herbal supplements and medications in industrialized nations, it is anticipated that the market for natural products is expected to see growth [75].

Herbal medicine incorporates a diverse array of pharmacological compounds derived from plants. These compounds have the potential to address a wide spectrum of health conditions and diseases. The Table 1 highlights various pharmacological compounds commonly found in herbal medicine and their applications in treating specific medical conditions. It's important to emphasize that these are just a few examples of plant-derived pharmacological substances used in herbal medicine. Furthermore, it's imperative to underline that the use of these substances, despite their natural origin, should be supervised by healthcare professionals to ensure safety and efficacy. Additionally, it is essential to be aware that the quality and dosage of herbal products can vary significantly, underscoring the need to source these remedies from reputable and recognized brands and suppliers.

3 The Situation Regarding Herbal Medication Worldwide

The global population is increasingly turning to natural remedies. In particular, multiple investigations have shown a generalized high prevalence [68] in individuals with chronic illnesses like kidney disease. However, the potential for damage from herbal medications is a source of worry. Literature examples emphatically demonstrate the link between herb consumption and renal illness. The need to ensure the safety of natural medications has grown in tandem with their popularity.

The World Health Organization (WHO) has recommended the integration of herbal medicines into established state pharmacovigilance systems [44]. To assess

Table 1 Pharmaceutical compounds derived from plants and the diseases they are used to treat

Compound	Derived from	Medical application
Artemisinin	*Artemisia annua* (sweet wormwood)	Malaria treatment
Morphine	*Papaver somniferum* (opium poppy)	Pain management, especially in cancer patients
Vincristine and Vinblastine	*Catharanthus roseus* (Madagascar periwinkle)	Cancer chemotherapy
Salicylates (Aspirin)	*Salix* spp. (willow bark) and other plants	Pain relief, anti-inflammatory, fever reduction
Quinine	*Cinchona* spp. (cinchona bark)	Malaria treatment
Reserpine	*Rauwolfia serpentina* (Indian snakeroot)	High blood pressure management
Etoposide and Teniposide	*Podophyllum peltatum* (Mayapple)	Cancer chemotherapy
Digoxin	*Digitalis* spp. (foxglove)	Treatment of heart conditions like congestive heart failure and atrial fibrillation
Atropine	*Atropa belladonna* (deadly nightshade)	Pupil dilation and treatment of certain heart and nerve-related conditions
Colchicine	*Colchicum autumnale* (autumn crocus)	Gout management and related inflammatory conditions
Ginkgolides	*Ginkgo biloba* (ginkgo tree)	Cognitive enhancement, particularly in age-related cognitive decline
Paclitaxel (Taxol)	*Taxus brevifolia* (Pacific yew)	Cancer chemotherapy
Cannabidiol (CBD)	*Cannabis sativa* (hemp and marijuana)	Pain management, epilepsy, anxiety, and various neurological conditions
Curcumin	*Curcuma longa* (turmeric)	Anti-inflammatory and antioxidant properties, used in health supplements
Ephedrine	*Ephedra* spp. (ephedra)	Used as a decongestant and for weight loss; restricted due to safety concerns

the risks and benefits of phytotherapy, a process known as phytovigilance, or the pharmacovigilance of medicinal plants, is employed. The ultimate goal is to prevent people from experiencing health issues as a result of using herbal remedies. It is of utmost importance to establish reliable data on the safety of natural medications [5]. Phytovigilance becomes a regulatory necessity when it comes to interactions between closely related plants due to the potential risks of toxicity, both acute and chronic, and medication interactions, whether of pharmacokinetic or pharmacodynamic nature.

India, being one of the 12 major biodiversity zones globally, boasts unparalleled biodiversity thanks to the presence of 16 distinct agro-climatic zones and 10 special agricultural zones. India is unique because it harbors not just one but two "biodiversity hotspots" [66]. In India, there are more than 45,000 plant species, including 15,000–18,000 flowering plant species, 23,000 types of fungi, 2500 types of algae, 1600 types of lichens, 1800 types of bryophytes, and 30 million microorganism species [6, 39, 40, 61]. The Indian subcontinent experiences a wide range of temperatures and environmental conditions, from glacial in the Himalayas to equatorial and humid in the south, and from the desert in Rajasthan to the north-eastern states with diverse topography, including grasslands, plateaus, mountains, and lowlands that accompany the mountains. The favorable environmental conditions, including soil quality, temperature, and humidity, contribute to the rich and diverse plant life found in the Indian subcontinent [69].

India's traditional medical practitioners, numbering over one and a half million, extensively utilize medicinal plants for disease prevention, development, and treatment. Additionally, more than 500,000 non-allopathic practitioners receive their education from one of the over 400 medical institutions to meet the healthcare needs of their respective systems [20, 69, 71]. The Indian subcontinent is renowned for its vast wealth of traditional knowledge and diverse vegetation, and it is crucial, both nationally and internationally, to preserve these resources for the benefit of all. In addition to its role in healthcare, the exchange of medicinal plants serves as a vital source of income for economically disadvantaged communities.

4 Global Trends in the Botanical Medicine Market and India's Role in the Industry

The market for botanical medicines has expanded at a phenomenal rate in recent years as a direct result of the widespread interest in alternative and conventional methods of medical treatment. Because of the profitable nature of the global botanical medicine market, the total value of world commerce in herbs is anticipated to reach USD 7 trillion by the year 2050. India only accounts for a relatively small portion of this global commerce [69]. According to the information that was readily accessible, the valuation of the market for botanical medicines in European countries was approximately USD 6 billion in 1991. This figure increased to USD 10 billion in 1996, which was anticipated to surpass USD 20 billion by 2000. In 1996, the United States contributed approximately 4 million USD to the global market for botanical medicines, while the total contribution from all other countries was 5 billion USD. Between May 1996 and May 1998 in the United States, sales of herbal products in conventional marketplaces increased by 101% [23, 40]. According to a publication that was released not too long ago by the WHO on traditional medicine, the total amount of money spent on traditional medicine in Japan in 2006 was just slightly more than one billion dollars, while the total amount of money spent on botanical medicine in Australia in 2004–2005 was 1.86 billion dollars. In China, traditional pharmaceutical preparations account for between 30% and 50% of the overall medication consumption, corresponding to a selling value of 14 billion USD in 2005 (an increase of more than 28.1% from the previous year). Even though expenditures in the United Kingdom and Brazil in 2007 were comparatively lower, totaling only 230 million and 160 million dollars, respectively [54]. Approximately 40% of all medical treatment delivered in China is in the form of traditional medicine. According to estimates made in 2002, Malaysia spent only about USD

300 million on allopathic medicine yearly while spending approximately USD 500 million annually on traditional and supplementary alternative medicine [75]. According to a different report by the WHO titled "Traditional Medicine," the yearly value of the worldwide conventional medicine business at the time was projected to be USD 83.1 billion in 2008. Additionally, this market is experiencing explosive growth. The annual revenue increase rate generated by sales of products relating to conventional medicine ranges between 5% and 18% [54]. Despite the country's enormous availability of natural resources, there is significantly less interest in using botanical medication in India than elsewhere. India and China are the two countries in Asia that have the largest populations and the most natural components taken together. According to Wakdikar [72], China has approximately 4942 species of therapeutic plants out of a total of 26,092 species, whereas India has only 3000 out of 15,000 plant species. However, compared to China and India, the number of plant varieties found in Indonesia, Malaysia, and Nepal is significantly lower – the total number of plants and therapeutic plants found across the globe. In the rapidly expanding international market for natural medication, India holds only a modest portion (1.6%). The percentage of the world's total output from India increased by 4.95% between 1991 and 2002, while the percentage from China increased by 7.38% during the same period [64, 71]. The Ayush Department of Health and Family Welfare of India reports that in 2009, India was the second biggest producer of therapeutic plants globally, behind China [13].

5 Renal-Related Health Consequences of Botanical and Supplement Usage

Traditional medical practices from various cultures worldwide have harnessed the therapeutic properties of various plants for centuries to address a diverse range of illnesses and conditions. While many of these medicinal plants have proven therapeutic value, it's crucial to recognize that certain plants can adversely affect kidney functions within the human body. The severity of these unintended effects can vary from mild to severe. Therefore, individuals and healthcare professionals must be aware of the potential risks involved. Some medicinal plants known to have detrimental side effects on renal functions.

(i) **Aristolochia Species:** Some plants within the Aristolochia genus, commonly known as birthwort or Dutchman's pipe, contain aristolochic acid. Exposure to aristolochic acid has been linked to developing a serious kidney condition called aristolochic acid nephropathy. This condition can lead to long-lasting kidney damage and, in severe cases, renal failure.

(ii) **Ephedra:** Also known as ma-huang, Ephedra has a history of use in traditional Chinese medicine for respiratory conditions and weight reduction. However, it contains ephedrine, associated with adverse effects like high blood pressure, dehydration, and kidney damage. Consumption of products containing ephedra has been linked to kidney-related health problems.

(iii) **Ginger (*Zingiber officinale*):** While ginger is generally considered safe and offers various health benefits, excessive or prolonged use of ginger supplements may negatively affect the kidneys. Those with pre-existing kidney issues should exercise caution.
(iv) ***Glycyrrhiza glabra* (Licorice):** Licorice root contains glycyrrhizin, linked to high blood pressure, low potassium levels, and potential renal impact. Extended or excessive consumption of licorice can lead to kidney problems.
(v) **Horsetail (*Equisetum arvense*):** Traditionally used as a diuretic, excessive horsetail use can lead to potassium deficiency, potentially affecting kidney function.
(vi) **Cascara Sagrada (*Rhamnus purshiana*):** Known for its laxative properties, prolonged or excessive use of cascara sagrada may result in dehydration, electrolyte imbalances, and potential kidney issues.
(vii) **Aloe Vera:** Topical use of aloe vera is generally considered safe. However, ingestion of aloe vera latex, which has laxative properties, can lead to diarrhea and potassium loss, affecting kidney function.

Other specific medicinal plants with adverse effects on the renal functions are summarized in Table 2. Furthermore, it is essential to note that the adverse consequences associated with these medicinal plants typically arise from excessive or prolonged use. When consumed in safe and moderate amounts, many of these plants may not pose a significant risk to renal function. Nevertheless, exercising caution and seeking advice from a qualified healthcare professional is essential before using medicinal plants, especially if you have a history of kidney problems, are pregnant, or are taking medications.

Additionally, many countries have established regulations and restrictions on the use of specific medicinal plants due to their potential for adverse effects. Therefore, always consult with a healthcare practitioner or herbalist before using any medicinal plant for therapeutic purposes to ensure its safety and effectiveness for your specific circumstances.

6 External Challenges in Herbal Medicine: Contaminants, Adulteration, and Misidentification

External quality challenges in herbal medicine are a significant concern due to their potential risks, including contamination, adulteration, and misidentification, which can have adverse consequences for patients.

6.1 Contamination

Heavy metals, herbicides, bacteria, and mycotoxins are some of the contaminants most likely to be discovered in botanical materials and herbal products; however, this list is not exhaustive [80]. Although the issues are everywhere, they appear more

Table 2 Renal-related health consequences of botanical and supplement usage

S. no	Herb	Country	Gender	Age	Reason	Preparation	Renal side effects	Causality	Reference
1.	*Dioscorea quinqueloba*	Korea	Male	51	Cardiovascular disease	Raw extract	Biopsy-proven acute interstitial nephritis	Certain	Sharma et al. [62]
2.	*Dioscorea quinqueloba*	Korea	Male	58	Health supplements and diabetes mellitus	Extract from tubers	Acute kidney injury	Possible	Muthuswamy and Senthamarai [50]
3.	*Glycyrrhiza glabra*	Serbia	Female	39	Sterility	Take liquorice-containing plant supplements daily for 8 weeks (50–100 g)	Acute renal failure	Probable	Payne et al. [52]
4.	*Chenopodium polyspermum*	Anatolia region, Turkey	Male	46	To regulate his blood glucose level	The medicine should be taken orally thrice in the month leading up to admittance, with the final dosage occurring around 10 days beforehand	Chronic renal failure	Possible	Mann et al. [47]
5.	*African mango (Irvingia gabonensis)*	Turkey	Female	42	Slimming purposes	She began taking two capsules of 500-mg African mango daily 3 months prior	Rapid renal progression	Probable	Payne et al. [52]
6.	*Lawsonia inermis*	Myanmar	Male	34	His face was puffy, and his complexion looked pale	consumed roughly 700 mL/day for 3 days' worth of cooked henna plants	Acute kidney injury	Probable	Mann et al. [47]

(continued)

Table 2 (continued)

S. no	Herb	Country	Gender	Age	Reason	Preparation	Renal side effects	Causality	Reference
7.	*Euphorbia paralias*	Tunisia	Male	28	Edema	Consumption of a single dose of a cooked Euphorbia para las shrub 10 days prior to	Acute renal failure	Possible	Mativandlela et al. [48]
8.	*Ayurvedic powder*	India	Male	32	Eczematous skin lesions	Ingestion of ayurvedic contained arsenic for the last 6 months	Acute kidney injury	Possible	Sivakumar and Jayaraman [65]
9.	*Carica papaya*	India	Male	63	Increase the platelet count	Juice extracted from papaya leaves	Acute kidney injury	Possible	Rehman et al. [55]
10.	*Trigonella foenumgraecum*	Iran	Female	61	Urinary tract infection	Taking a fenugreek seed decoction that has been heated every day	Died of renal failure	Certain	Mann et al. [47]

widespread in countries across Asia, most notably China and India, the most populous regions that manufacture and consume the most natural medications. In addition, contaminations are a significant barrier to the commercial distribution of natural medications.

6.1.1 Heavy Elements

Heavy metals are a recurring issue in natural remedies [1, 2, 37], with the most common culprits being mercury, arsenic, and lead. Contaminants like cadmium, copper, and thallium have also been identified [16–18]. These toxic heavy metals are frequently detected in traditional Asian medicines, particularly Chinese patent medicines (CPMs) and Indian Ayurvedic medicines (IAMs). Both are abbreviated as [CPMs] and [IAMs] [51].

Contamination with heavy metals can occur due to several factors:

1. **Environmental Accumulation:** This can result from heavy metals accumulating in the environment, such as contaminated soil or air.
2. **Accidental Pollution:** During the manufacturing process, accidental contamination can occur.
3. **Intentional Inclusion:** Some traditional medical systems intentionally use minerals, including toxic metals, in the preparation of remedies. For instance, certain cosmetic formulations require the use of substances like Zhusha (Cinnabaris) and Xionghuang (Realgar), which contain mercury and arsenic. Realgar is also known as Xionghuang [84].

It's important to note that labeling this intentional inclusion of heavy metals as "contamination" is inaccurate. This practice is based on outdated beliefs and doesn't align with modern scientific research, as there is no evidence to suggest that the benefits of heavy metals outweigh the associated health risks [46, 73]. Stricter quality control measures in industrialized countries reflect the need to prevent such practices and ensure the safety of natural medicines.

6.1.2 Pesticides

Pesticides, which encompass insecticides, fungicides, and herbicides, can have far-reaching implications for the quality and safety of botanical medications. These chemicals and their byproducts can persist in plants, animals, and the environment where they were used, posing a significant contamination risk to herbal products. To address this concern, the World Health Organization (WHO) and other organizations have established guidelines to limit the presence of pesticides in botanical products [76].

Organochlorine pesticides (OCPs), such as benzene hexachlorides (BHC), pentachloronitrobenzene, and dichloro-diphenyl-trichloroethane (DDT), are often identified in natural medications (PCNB). Despite being banned in many countries for approximately three decades due to their detrimental effects on human health, OCPs can persist in the environment and accumulate in the food chain due to their slow degradation. However, they are less common than other types of insecticides, particularly those containing organophosphorus and carbamate compounds, which are frequently detected in natural medications. Some naturally occurring substances have even been found to contain traces of more modern chemicals like fenvalerate and deltamethrin.

Modern agriculture extensively employs pyrethroid herbicides due to their high effectiveness and low toxicity to humans and the environment [9]. Research in China has shed light on the issue of herbicide residues in medicinal materials, affecting both domestic and international sources, including plants like *Panax notoginseng*, *Panax quinquefolium*, and *Panax ginseng*, among others [45]. These studies identified five types of pyrethroid insecticides, with 14.8% of samples exceeding permissible limits, and revealed more significant damage to above-ground parts compared to roots [79]. OCPs, consisting of nine different types, were found to exceed permissible limits in 7.09% of samples, with roots being more affected than above-ground parts [83].

Furthermore, contamination can result from the improper application of pesticides used for soil disinfection (e.g., PCNB) and excessive or untimely application close to harvest. The use of insecticides during storage and fumigants like sulfur dioxide to prevent insect or fungal infestations can also contribute to residue contamination [84]. The environmental consequences of OCPs leaching into the soil further compound these challenges.

6.1.3 Microorganisms as well as Mycotoxins

The risk of microbial contamination in natural medications is a prevalent concern. Botanical compounds have been found to provide a conducive environment for pathogenic microorganisms, including enterobacter, enterococcus, shigella, and streptococcus [8]. Mycotoxins, such as fusarium toxin, ochratoxin, penicillic acid, citreoviridin, and particularly aflatoxins, pose significant health hazards and can be present in considerable quantities.

Studies have indicated that over half of the samples of medicinal plants sourced from a Brazilian market exceeded the microbial contamination limits set by the United States Pharmacopeia (USP). Similar findings from various research have consistently highlighted issues of fungal contamination and mycotoxins in natural medications, not only in India but also in countries like China, South Africa [67], Malaysia [3], and Indonesia.

The risk of microbial contamination can occur at various stages of the manufacturing and distribution processes of herbal medicines. Quality control is particularly affected by storage and manufacturing conditions. High temperatures and elevated moisture levels, prevalent in tropical and subtropical regions, create an environment conducive to fungal growth and mycotoxin production [56].

6.1.4 Other Unidentified Foreign Material

Additional forms of foreign matter that can contribute to the external contamination of botanical medications include ash, adjuvants, and organic solvents [22]. To maintain a high level of quality in the final product, minimizing the impact of these contaminants is crucial.

Adulteration:

1. Can involve replacing authentic plant materials with substandard or false alternatives, further undermining product quality.
2. **Incorporation of Foreign Materials:** The inclusion of foreign substances, such as non-officinal herb parts, sand, or metals, can also occur.

There have been documented instances of pharmaceuticals being discovered in herbal medications, with reports of adulteration rates estimated at 1.24% in Singapore, 7.1% in New York, and 7% in California [81]. More recently, sildenafil, the active ingredient in Viagra, has been found in products labeled as tonics.

Adulteration is often motivated by financial gain, as unscrupulous parties fraudulently seek to increase the weight or abundance of botanical materials. These deceptive practices can occur at various stages of the manufacturing process, from the early production steps to later stages.

It's important to note that while including lawful, manufactured medications within natural remedies is not classified as adulteration, it is illegal to market herbal medications containing undisclosed conventional pharmaceuticals. Adequate supervision and control are essential to prevent the mislabeling and adulteration of herbal products.

Addressing the issue of adulteration requires the implementation of rigorous regulatory measures. For these measures to be effective, they must be enforced and adhered to consistently. Stringent oversight and regulation are essential to maintain the quality and safety of herbal remedies.

6.2 Misidentification

In contrast to deliberate acts like adulteration or displacement, typically arises from unintended errors. It occurs when a supplier or merchant mistakenly confuses one botanical material for another, often due to incorrect labeling and a superficial resemblance between various plant specimens [10].

Several factors can contribute to such misidentification. One primary cause is the often confusing nomenclature of plants. A single plant may have multiple names, including common names, Latin-derived names, terms from original languages, and brand-specific names. Furthermore, different medicinal plants from distinct species, each containing various therapeutic components, may share the same or similar titles. This situation leads to the terms "Mutong" and "Fangji" being applied to multiple plant species originating from various biological families that are not related.

The consequences of misidentification can be severe. For instance, the dangerous condition known as aristolochic acid nephropathy has resulted from the improper identification of "Mutong," wherein Caulis akebiae was mistakenly substituted for Caulis aristolochiae manshuriensis. The complexities of plant identification are exacerbated by factors such as the visual resemblance of plants, ambiguities in historical records, and variations in regional usage patterns. The use of perplexing terminologies and linguistic differences across countries further complicates the matter.

In many cases, the common names of plants do not accurately reflect their scientific classifications. The physical description of a plant or its examination under a microscope may not always reveal the specific components relevant to herbal medicine. As a result, the accurate authentication of botanical materials often necessitates a combination of historical research and the application of contemporary scientific methods.

Efforts are being made by organizations like the World Health Organization (WHO) and others to standardize and harmonize biological nomenclature to mitigate misidentification issues in the herbal and botanical product industry [10].

7 Excellent Facility for the Stockpiling of Plants

The storage facility should be equipped to accommodate plants designated as “Under test,” “Approved,” and “Rejected.” It must also provide the necessary infrastructure for washing, drying, and orderly storage of herbs, along with climate control to regulate temperature and humidity. Compliance with Good Manufacturing Practice (GMP) regulations is essential in the storage area, covering aspects such as plant handling, drying space allocation, and overall facility management.

For storage areas falling under GMP regulations, several requirements must be met. These include adequate air circulation, moisture control, and sufficient space for various types of materials. In line with GMP guidelines (A), the following list identifies the types of storage suitable for various herb-related products:

- Fresh plants
- Dried herbs
- Concentrates and plant material preparations

These measures are essential to ensure that the storage of herbs and related products complies with GMP standards and maintains their quality.

8 Quality Control and Proper Storage of Fresh Medicinal Plants

8.1 Processes Involved in the Correct Storing of Fresh Plants

The process involves several key steps:

(i) **Herb Identification:** Initially, herbs are identified using human senses. This includes assessing their appearance, aroma, and other sensory characteristics to ensure they match the desired specifications.

(ii) **Cleaning of Herbs:** Herbs can include various plant parts like flowers, vegetables, and other components. Cleaning involves washing unprocessed drug materials, such as stems, foliage, roots, leaves, and stalks, with potable water to remove impurities and contaminants.

(iii) **Drying of Unprocessed Plants:** After cleaning, uncooked plants are dried in their basic form. This step helps preserve the herbs and prevents moisture-related issues.

(iv) **Microorganism Elimination:** To ensure the safety of herbal products for internal use, it's crucial to consider bacterial limits and the risk of mold contamination, similar to food products. Many herbal products undergo sterilization, typically using ethylene oxide and specialized equipment. It's important to note that disinfection kills bacteria but not their spores, while sterilization eradicates all forms of bacterial life, including spores.

(v) **Sterility Testing:** To confirm that a product is sterile, it must be entirely free of any living organisms. Sterility testing is performed to ensure that the product meets these criteria.

These steps are vital in the preparation and quality control of herbal products, guaranteeing their safety and effectiveness for consumers.

8.2 Process of Sterilizing Fresh Plants

Raw plants intended for preservation can undergo sterilization using several methods, depending on the specific requirements of the situation. These sterilization techniques include:

(i) **Dry Heat Sterilization:** Dry heat sterilization is the most commonly used method. It involves the use of high temperatures to eliminate microorganisms and other contaminants from raw herbal materials [25].

(ii) **Steam Sterilization:** This method employs steam to achieve sterilization.

(iii) **Radiation Sterilization:** Radiation-based methods like infrared radiation, UV rays, X-rays, gamma rays, alpha radiations, and beta radiation can be used for sterilization.

(iv) **Chemical Sterilization:** Gaseous sterilization, such as using ethylene oxide, is another effective technique to ensure sterilization.

Raw herbal medicines should be stored at a specific temperature range between 80 °C and 250 °C. Protecting them from environmental factors like moisture, freezing temperatures, excessive heat, and light is crucial. These precautions are essential to prevent the deterioration of raw plants during storage.

8.3 Evaluation of High-Grade Unprocessed Plants

Following the guidelines set forth by the WHO, testing of fresh plants is essential and involves a series of crucial assessments:

(i) **Authentication:** Taxonomic research and botanical identification are conducted to verify the plant's species and origin.
(ii) **Contamination from Foreign Matter:** Herbs must be free of contaminants like dirt, stones, pollen, insects, or other foreign materials.
(iii) **Organoleptic Assessment:** This assessment considers the macroscopic appearance of the substance, including its odor, flavor, texture, color, and overall sensory characteristics.
(iv) **Microscopic Investigation:** Microscopic analysis provides valuable data for species identification, including details such as stomata type and artery thickenings.
(v) **Extraction of Volatile Substances:** The extraction of volatile oils, like in species such as mentha and ocimum, through techniques like steam distillation, is essential for quality control assessment.
(vi) **Ash Content:** The ash content in a medicinal plant can be measured as Total Ash, Acid Insoluble Ash, and more. The presence of insoluble acid in water suggests contamination with organic substances.
(vii) **Extractive Values:** Extractive values offer additional insights into the quality of raw plant materials.
(viii) **Chromatographic Profile and Marker Component:** Techniques like Thin Layer Chromatography and High-Performance Liquid Chromatography (HPTLC) are used to determine the chromatographic profile and identify marker components in the substance.
(ix) **Pharmacological Evaluation:** This assessment involves determining the foaming index, hemolytic activity, and bitterness value of the plant material, considering its pharmacological aspects.
(x) **Residues of Toxicological Pesticides:** Pesticides are used to reduce insect, fungi, and mold prevalence in fresh plants. It's essential to analyze for toxicological pesticide residues, especially if the medicinal plants are consumed over an extended period.
(xi) **Microbial Contamination:** Analysis for the presence of bacteria, molds, and aflatoxins is carried out to ensure the plant material's safety and quality.

These assessments collectively ensure the quality, safety, and authenticity of fresh plants used in medicinal applications.

8.4 Testing of Fresh Plants

Testing fresh plants serves various purposes, including morphological examination, microscopic evaluation, identification testing, purity and strength assessment, thin-layer chromatography (TLC), and constituent testing. To maintain the quality, safety, and potency of plant materials, adherence to proper handling, packaging, and storage is crucial.

Ensuring the correct storage of raw botanical substances is paramount, despite the absence of specific recommendations to date. Various environmental factors like oxygen, moisture, sunlight, and pollen can adversely affect plant materials and should be minimized or avoided. The ideal storage area should be dry, free from moisture, humidity, and protected from intrusions by animals, birds, insects, and similar factors.

Furthermore, distinct storage areas are necessary for different classifications of medicinal and aromatic plants, including fresh herbs, dried herbs, extracts, gums, essential oils, and potentially harmful substances, as outlined in the Drug and Cosmetic Act of 1940.

To facilitate efficiency, separate sections should be designated for items “Being Tested,” “Approved,” and “Rejected.” It’s essential to avoid storing plants that appear nearly identical in the same area to prevent potential misidentification.

Each batch of stored plants should bear an identification label, including details such as the test result date, consignment number, arrival date, best-before date, batch number, and storage location.

Authenticated reference samples must be maintained within the facility for reference. Additionally, to ensure proper storage, plants should be kept in containers placed on hardwood or plastic shelves, with each container housing a single plant. The appropriate choice of container material is crucial.

It’s crucial to avoid certain practices, such as storing plants in exposed areas, placing them immediately on surfaces, storing them near similar drugs, using inappropriate container materials, mixing authorized and unverified quantities, and storing the substances for extended periods at abnormal temperature and humidity levels. Proper storage practices are vital to maintain the integrity and quality of plant materials.

9 Strategies for Dealing with Exterior Obstacles

Environmental concerns related to natural medicinal products encompass cultivation, production, and distribution. Strict adherence to “Good Agricultural and Collection Practices” (GACP), often referred to as “Good Practices,” is a critical step in elevating the overall quality of herbal medicines. In 2003, the World Health Organization (WHO) recommended the adoption of GACP for medicinal plants. This standard has been adopted at the national and regional levels in various countries and regions, including the European Union, China, and Japan. In addition to adhering to GACP, the manufacturing of herbal products must follow the Generally Accepted Manufacturing Procedures (GMP) [77].

Furthermore, the distribution of natural remedies should be carried out following Good Supply Practices (GSP). Between 2004 and 2009, Wang et al. [73] certified various national GACP bases in China, which are specific locations for cultivating botanical medicines in compliance with GACP standards. These bases were established across China, totaling 430 municipal GACP sites covering an extensive cultivation area of approximately 11,000 km^2 [84]. The implementation of GACP has notably improved the quality of medicinal ingredients used in Chinese medicine.

However, it's essential to acknowledge that the journey toward this achievement has not been without its challenges.

Sustained issues persist due to the inadequate application of scientifically sound standard operating procedures (SOPs), standardized management practices, well-trained farming personnel, and other relevant experts [82]. The effective implementation of these principles, such as GACP and GMP, is vital for ongoing success. Companies specializing in herbal products are at the forefront of advocating for the high quality of natural remedies. Manufacturers of herbal products must provide assurances of the quality of their products to comply with national regulations and ensure the safety and effectiveness of natural medicinal products.

10 Obstacles to Quality and Regulations

The extensive use of botanical medications for disease prevention, detection, treatment, and management presents significant global challenges in terms of product control and relevant regulations. The quality, safety, and effectiveness of these substances are of paramount concern due to their widespread and increasing utilization in healthcare. To advance conventional medical practices, scientific validation and technological standardization of botanical medicine are indispensable.

The application of products adhering to established quality assurance standards holds the potential to significantly reduce the risks associated with natural medicine. However, herbal medicine regulations and legislation have been implemented in only a few countries, leaving a majority without adequate oversight of botanicals, leading to a lack of guaranteed quality in herbal products despite existing regulations [74, 75].

Recently, several European countries adopted the European Directive on Traditional Herbal Medicinal Products, which aims to regulate and ensure the quality of herbal products. In the United Kingdom, the Medicines and Healthcare Products Regulatory Agency (MHRA), formed in April 2003 through the merger of the Medicines Control Agency and the Medical Devices Agency, is responsible for enforcing this directive, ensuring the quality and safety of all medicines.

Given the absence of such regulations in many countries, particularly in parts of Africa and Asia, the establishment of global regulations is urgently required. While extensive research is conducted on natural products, only a few clinical studies yield satisfactory findings that can be integrated into the conventional medical system. Research into herbal products remains notably deficient, with clinical studies for isolated active phytoconstituents being few, having small sample sizes, and insufficient controls.

The evaluation of botanical remedies' efficacy is inherently challenging, primarily due to the accurate identification of plants and the isolation of their active components. Medicinal plants' characteristics can vary significantly over time, and a single plant may contain hundreds of naturally occurring components depending on factors like harvesting, geographical origin, and environmental conditions. This complex process necessitates prompt action on various fronts, including legislation and supervision for botanical products, treatment practices, education, training, practitioner licensing, research and development, and the allocation of financial and other resources [40, 75].

Several critical obstacles need to be overcome to promote the development of herbal medicine:

1. **Education and Training:** The first challenge is to ensure that both conventional and alternative medicine practitioners possess the necessary knowledge, certifications, and training. Educational programs are required to help these practitioners recognize and appreciate the complementary nature of their respective practices.
2. **Protection of Indigenous Knowledge:** It is imperative to address issues related to the protection of indigenous traditional knowledge and the proper use of this knowledge. Many traditional herbal medicine systems lack robust scientific evidence of their efficacy, and concerns about intellectual property need to be resolved to prevent the theft of indigenous natural resources and traditional knowledge to produce traditional medicines [75].
3. **Sustainable Plant Harvesting:** Sustainable harvesting of medicinal plants is essential to prevent their depletion. Many therapeutic plants are sourced from natural resources, with unsustainable harvesting practices being a primary cause of their destruction. Over 70% of plant gathering is detrimental due to the extraction of parts or the entire plant, leading to plant eradication, which is particularly problematic for species with low populations. To preserve the genetic diversity and complexity of plants used for therapeutic purposes, sustainable harvesting practices are imperative [61].
4. **Regulations and Standards:** Establishing regulations and standards for inexpensive pharmaceuticals and herbal medicines is another hurdle that must be addressed. Inadequate legislation, underdeveloped infrastructure for small-scale businesses, and a lack of stringent quality standards for botanical substances and compositions hinder the standardization of herbal medicine [71].
5. **Good Manufacturing Practices (GMP):** Implementing GMP is crucial to ensure that herbal medicines meet the highest quality standards. Good Manufacturing Practices are designed to guarantee the quality of natural medicines, and their adoption is an immediate necessity.
6. **Clinical Studies:** Rigorous clinical studies demonstrating the safety and efficacy of herbal treatments, particularly when combined with allopathic pharmaceuticals, are essential. These studies should employ randomized, double-blind, placebo-controlled methodologies to meet the high standards expected by the public. Conducting systematic clinical studies will open up new opportunities for fundamental and applied research on botanicals and Ayurvedic treatments in India.
7. **Pharmacopoeias:** The development and expansion of pharmacopoeias is vital. In India, GMP was introduced for Ayurvedic, Siddha, and Unani medicines in 2000. The Indian Pharmacopoeia also included many books on flora and medicinal products. The 2010 edition featured 89 such books, compared to 59 in 2007. Additionally, the Ayurvedic pharmacopoeia documented 258 medications in

2005, and the Indian Herbal pharmacopoeia detailed 52 different medicinal plants, both of which are Indian publications [24, 74].

Addressing these challenges is essential to ensure the growth and acceptance of herbal medicine and to provide safe, effective, and standardized treatments to the public.

11 Initiatives Were Taken in the Field of Natural Medicine

In India, there is an urgent need to expand research in agro-pharmaceutics, plant biotechnology, and the pharmaceutical industry to boost the production of medicinal plants and their active constituents by harnessing modern genetic and biotechnological techniques. Despite numerous institutions and colleges across India, research in this field is notably insufficient compared to countries such as Mainland China, Tokyo, Europe, and Jerusalem. To address this shortfall, it’s imperative to encourage the active involvement of Agricultural, Medical, and Pharmaceutical schools, along with botanical research organizations, in conducting fundamental research.

Another significant challenge hindering the global expansion of Indian traditional medicine is biopiracy. Developed countries tend to dominate the patenting of products, putting less developed nations like India at a disadvantage [39]. Moreover, the degradation of biodiversity, excessive commercialization, and industrialization pose obstacles to the growth of natural medicine. In contemporary times, the reluctance or inability of people to apply traditional knowledge inherited from their ancestors regarding plants, medicines, and remedies contributes to the scarcity of educated individuals in the field of alternative and complementary health [70]. Consequently, the development of Indian traditional medicine requires comprehensive documentation of traditional knowledge, patenting efforts, and the continuation of previous research efforts.

Key priorities for this sector include standardizing drug quality, increasing the supply of medicinal plant materials, conducting further research, developing new treatments, and raising awareness about the effectiveness of traditional systems. During the government’s 10th five-year plan, the AYUSH Department received approximately 158 million US dollars (about 775 billion Indian rupees) in funding. In November 2000, the Government of India established the National Medicinal Plants Board (NMPB) to address issues related to medicinal plants and promote their trade, conservation, and sustainable production. Since then, the NMPB has been diligently pursuing these objectives, developing various programs and initiatives during the 11th 5-year plan (2007–2012) to protect rare, endangered, and threatened plant species while promoting the sustainable management of medicinal plants.

Government initiatives and programs in India allocated USD 65.21 million (INR 320 crores) for addressing various issues related to patents and intellectual property rights [20]. An essential strategy to combat these problems involves providing financial support for research aimed at documenting indigenous knowledge.

Concerns about biopiracy have driven India's efforts to safeguard its traditional knowledge, particularly in light of several instances.

The Traditional Knowledge Digital Library (TKDL) is a pioneering effort in India to tackle these issues. Established in 2001 as a collaborative project between the Council of Scientific and Industrial Research of India and the Department of AYUSH of the Government of India, the TKDL is the first of its kind. It is dedicated to archiving traditional knowledge that is already part of the public domain, particularly information related to Ayurveda, Unani, and Siddha systems of medicine. The TKDL contains approximately 212,000 different medicinal formulations, including 82,900 from Ayurveda, 115,300 from Unani, and 12,950 from Siddha.

By September 2010, the TKDL database reported that the European Patent Office (EPO) had revoked 23 patent applications and set aside three patents. In addition, the EPO withdrew three patents in the same period. Consequently, the number of patent applications for Indian medical practices at the European Patent Office saw a significant reduction of 44%. This suggests that the TKDL has been effective in protecting against biopiracy.

Furthermore, India has implemented a global biopiracy monitoring system within the TKDL to scrutinize patent applications associated with Indian medical practices [21, 63].

12 Challenges Associated with the Medicinal Plants Practice

Working with medicinal plants presents unique challenges that must be understood and addressed to guarantee the safety and efficacy of herbal therapies. Table 3 offers a summary of the most significant issues associated with the use of medicinal plants. To address these challenges, collaboration between researchers, healthcare professionals, traditional practitioners, and government officials will be essential.

Balancing the preservation of traditional knowledge with its integration into modern healthcare systems is crucial. Simultaneously, it is imperative to ensure that medicinal plants are both safe and effective while remaining readily accessible for the benefit of all individuals.

13 The Function and Its Prospects for the Future

The demand and development of natural medications are set to continue, ensuring a prosperous future. This ongoing internationalization of medicinal herbs and ethnobotanical research will lead to the discovery and utilization of novel plant products for various applications, including construction, medicine, and industry [38, 57]. Notably, the expansion of natural medicine holds significant economic potential for India. Consumers must have access to untampered products, highlighting the need for quality and safety assurance in herbal remedies.

The proliferation of botanical medicine has provided an alternative healthcare system, essential for enhancing global healthcare accessibility. The delayed

Table 3 Challenges associated with medicinal plant practice

Challenge	Description
1. Quality control	Ensuring consistent quality of medicinal plants despite variations in climate, soil, and harvesting methods
2. Standardization	Standardizing herbal remedies for consistent dosages of active ingredients, critical for clinical efficacy
3. Regulation and quality assurance	Herbal products often have less stringent regulation, posing risks due to lack of standardization and control
4. Authentication and identification	Correctly identifying and authenticating plant species to prevent misidentification and ineffective treatments
5. Sustainability	Preventing environmental degradation and plant species endangerment due to overharvesting
6. Cultural and ethical considerations	Integrating traditional cultural and ethical aspects into modern healthcare can be challenging
7. Research and evidence	The need for rigorous scientific research to validate the safety and efficacy of medicinal plants
8. Biopiracy	Protecting indigenous knowledge and ensuring fair benefit-sharing to counter unauthorized commercial use
9. Globalization	Challenges arising from global trade, regulation, and standardization discrepancies between countries
10. Education and training	Building a skilled workforce knowledgeable about medicinal plants through training and education
11. Patient safety	Ensuring practitioners are aware of potential interactions between herbal and conventional medications
12. Access and affordability	Balancing the accessibility and affordability of herbal remedies for all socioeconomic groups

awareness of declining medicinal plant supplies is attributed to the increasing global demand for herbal remedies. India's diverse environmental conditions have endowed it with a wealth of therapeutic plants, making it a leader in this field [63]. It's imperative to combine modern knowledge with traditional wisdom.

Culturing profitable medicinal plants in neglected areas can boost national economies, as seen in North Eastern India [60]. The government should promote private cultivation of these plants to ensure a sustainable supply, ultimately benefiting the economy's long-term health and creating employment opportunities in remote regions. Policies and planning strategies must align with the economic forecast to fully unlock this sector's potential [40, 63].

In today's world, harnessing the potential of traditional botanical medicines and integrating them into public healthcare systems is crucial. India's abundant therapeutic plants, in high demand in international markets, should be explored further in areas like Agrotechnology, Natural Products, Quality Assurance, and Control of homoeopathic medicines. Understanding the socioeconomic context and supporting research are essential for the industry's sustainable growth.

Preserving the biodiversity of therapeutic plants and preventing biopiracy are critical factors for the industry's expansion. The time has come to compile and document traditional wisdom about our invaluable plant resources and conduct comprehensive research into their phytochemical, biological, and pharmacological properties to demonstrate their effectiveness.

14 Conclusion

This chapter primarily emphasizes the quality concerns associated with Eastern medicinal medications. Strict adherence to Good Agricultural and Collection Practices (GACP) and Good Manufacturing Practices (GMP) can significantly reduce the risks of contamination, adulteration, and other issues. By incorporating contemporary scientific methods and techniques from the pharmaceutical industry, it becomes possible to produce standardized botanical products that are easily manageable in terms of quality. However, it's important to note that there has been limited success in achieving consistent quality control for natural medications.

To achieve an overall improvement in the quality of these products, it is essential to prioritize two key areas: enhancing regulatory measures and conducting additional methodological studies. Government organizations should play a crucial role in providing active guidance and effective legislation in this regard.

Furthermore, utilizing specific packaging materials tailored to different parts of medicinal herbs allows for controlled storage conditions, including temperature, pressure, air, and light. Proper labeling should be a part of this provision to ensure the preservation of the herbs' active constituents during storage in various facilities. This approach not only safeguards the efficacy, safety, and quality of Ayurvedic medicines but also taps into the substantial economic opportunities presented by the expanding pharmaceutical market in our country.

Acknowledgment We would like to extend our sincere appreciation and gratitude to the Department of Agronomy at the School of Agriculture at Lovely Professional University, Punjab, 144411, India.

Abstract

Herbal or Phyto medicines have been used since time immemorial as a form of traditional medicine systems and practices like Ayurveda, Siddha, Unani, and homeopathy. This medical system uses herbal medicines, or phytomedicines that are extracted from herbal plants, for the treatment of diverse diseases. People in developing countries such as Asia and Africa rely on herbal medicines for the treatment of various diseases the most because it is believed that they are cheaper, more effective, and risk-free. Herbal medicines are preferred over modern med-

icines in developing countries. However, herbal medicines suffer from a lack of scientific data on their effectiveness and adverse effects. But for the treatment of some serious disease conditions, phytomedicine formulation must be standardized and developed. Following the COVID-19 pandemic, the demand for herbal medicines has grown and commercialization challenges for herbal medicines are expected to also increase. Nonetheless, efforts should be made to increase the commercialization of herbal medicines by searching for their formulations, development, and methodology so that medicines can be made available for addressing serious diseases. This chapter focuses on some of these challenges and how to improve them.

1 Introduction

Herbal medicine has been regarded as a promising future medicine for the management of healthcare in the twenty-first century due to its increased pharmacological efficacy. The worldwide trend toward herbal medicine, which is known as a “Return to Nature,” has recently changed. Since ancient times, medicinal plants have been used to treat a variety of ailments and diseases, and they are widely regarded as a rich source of therapeutic agents [1].

In industrialized nations, herbal medicine sales have skyrocketed over the past 10 years. Some of the conditions for which herbal medicines are increasingly being used, i.e., the emergence of new, severe diseases, include insomnia, anxiety, obesity, bronchial asthma, congestion, gingivitis, Vincent's disease, eczema, varicosity, and immunodeficiency syndrome. Other conditions include (i) varicosity and immunodeficiency syndrome; (ii) problems for which there is currently no effective treatment and the belief that herbal remedies are safer than pharmaceuticals; (iii) the idea that only good things can come from nature; (iv) the specific spotlight on the climate. In Western nations, movements promote herbal remedies and the belief that natural herbal remedies are superior to synthetic ones. The advancements made in the production and preservation of herbal medicines are another factor. Today, medicinal plants that are rich in desirable active compounds can be introduced to the market thanks to the possibility of cultivating genetically modified varieties [2]. One percent of the estimated 25,000 to 75,000 plant species used in traditional medicine are recognized by scientists and accepted for commercial use [3]. Traditional medicine, as opposed to conventional "Western" drug therapy, is still the only health service that most people in many developing countries can afford. For people who live in these areas, traditional medicine is the first line of defense and basic healthcare [4]. The utilization of plants, portions of plants, and secluded phytochemicals for the counteraction and treatment of different well-being diseases have been practically speaking from days of yore. One hundred twenty-one such active compounds are in use, accounting for approximately 25% of all prescribed medications worldwide [5]. However, conventional medicines have largely influenced the development of the current pharmacovigilance model, its activities, and associated tools. Due to the particular characteristics of herbal medicines as well as the various ways in which herbal medicines are regulated, used, and perceived, applying these methods to monitor the safety of herbal medicines presents additional challenges [6]. At several different levels, people are becoming more aware of how important it is to develop pharmacovigilance procedures for herbal medicines. The current pharmacovigilance model and the tools that go along with it were made for synthetic drugs. Using these methods to monitor the safety of herbal medicines is different from using them to monitor the safety of conventional medicines [7]. Traditional Chinese medicine (TCM) was used in 91.50% of COVID-19 cases in China, showing encouraging results in improving symptom management and reducing the rates of deterioration, mortality, and recurrence, as the coronavirus disease 2019 (COVID-19) pandemic poses a significant threat to global public health. For the treatment of COVID-19 in China, a total of 166 modified herbal formulas containing 179 individual herbal medicines were gathered [8].

Atropine, colchicine, digoxin, taxol, and vincristine are just a few of the isolated plant constituents that have made their way into the prescription drug inventory. Based on the depth that pharmacognosy brought to pharmacy curricula in the past, the significance of plant-derived medicine (phytomedicine) is obvious. However, just being familiar with chemistry and botany does not always translate into a comprehension of clinical pharmacology and therapeutics. More and more clinical courses and continuing education programs are including herbal medicine, and pharmacists are now able to access additional published sources of information [8].

Traditional medicine, as opposed to conventional, “Western” drug therapy, is still the only health service that can be afforded by the majority of people in many developing countries. Traditional medicine serves as a first line and basic health service for people who live in these areas. In industrialized countries, the situation is quite different because modern medicine’s services are readily available. However, traditional medicine has gained popularity in recent years and is now one of many important options for healthcare. Patients may be looking for less invasive alternatives to healthcare in this consumer-aware era. The revival of traditional medicine’s interest and popularity also follows its promising potential for treating certain diseases, such as malaria and chronic eczema [9].

Due to an epidemic like Corona, people had to take care of their traditional herbal remedies at that time. As a consequence of this, people remembered the Ayurvedic, Unani, and Chinese medicine systems, which in turn brought to mind herbs and herbal remedies, so this book chapter aims to achieve the development of herbs, herbal medicines, and herbal preparations with the regulations of herbal medicines in developing countries, its uses and commercialization by the evaluation of herbal preparations.

2 Herbal Medicines: An Overview

The creation of new Pharmaceuticals relies heavily on medicinal plants. The World Health Organization says that plants used in traditional medicine have been the source of nearly 25% of modern medicines [10]. The practice of using a plant’s seeds, berries, roots, leaves, bark, or flowers for therapeutic purposes is known as herbal medicine, botanical medicine, or phytotherapy. How Plant-based medicines are used in different countries in very different ways. Herbal medicine can be considered either a traditional or a complementary treatment depending on where and how it is used. Because the use of herbal medicines is frequently intertwined with local customs and beliefs about the workings of the body and the nature of health and disease, herbal medicines are an important part of the majority of indigenous forms of medicine, which are called ethnomedicine [4]. In many developing nations, herbal medicines are the most common form of treatment for a wide range of conditions. Currently, herbal products can only be sold as food supplements in the United States, and the FDA (Food drug administration) requires FDA approval before a manufacturer or distributor of herbs can make any specific health claims. The Dietary Supplement Health and Education Act (DSHEA) of 1994 regulates herbal medicines as dietary supplements, so they are exempt from the premarketing regulatory clearance that is required for drugs. The Food and Drug Administration of the United States bears the burden of proving that a dietary supplement is unsafe. In contrast, pharmaceutical drugs cannot be approved until their safety and effectiveness have been demonstrated by the manufacturer [11]. It was reported that natural products are the basis for more than 60% of cancer drugs currently on the market or in testing. Presently, around 80% of antimicrobial, immunosuppressive, cardiovascular, and anticancer medications are gotten from plant sources. Among the 177 approved anticancer drugs, more than 70% are based on natural products or mimics. Nearly 121 plant-based prescription medications are in use worldwide, accounting for approximately 25% of all prescription medications. Between 2005 and 2007, 13 natural product-based drugs were approved in the United States, and over 100 natural product-based drugs are currently undergoing clinical trials. Additionally, it was estimated that 11% of the 252 medicines on the WHO essential medicine list are not of plant origin [12]. Products derived from plants became the most popular option for biological and Pharmacological research, as well as the starting point for the creation of synthetic drugs. It is estimated that indigenous medicine was used to make up nearly 75% of all herbal medicines used today [13]. The current pharmacopeia, which is based on the pharmaceutical market, was inspired in large part by herbal medicines. Due to their lack of side effects and healthier alternatives for patients, herbal medicines are preferred over modern ones. The majority of the world's population, 85% used herbal medicines to treat skin conditions like viral, fungal, diabetic, hypersensitive, and other conditions. However, despite their appropriate pharmacological activity, they are less utilized in medical practices for a variety of reasons, including difficulties with solubility, bioavailability, and the need for high doses, among others [14]. Herbs, herbal materials, herbal preparations, and finished herbal products are included in the WHO definition of herbal medicines. Herbs are plant parts like leaves, flowers, fruits, seeds, stems, wood, bark, roots, rhizomes, and other parts that can be whole, broken up, or ground up into a powder. Herbal materials are either whole medicinal plants or crude parts of plants. Fresh juices, gums, herbs, fixed oils, essential oils, resins, and dry herb powders are all included [15]. In Western nations, herbal medicinal products (HMPs) are becoming increasingly popular. In 2005, a survey found that 71% of Canadians were using natural health products, which include vitamins and minerals as well as HMPs. In this study, herbal remedies and algal/fungal products were used by 11% of those surveyed. According to Kennedy (2005), about 19% of adults in the United States were using HMPs in 2002. According to another study, approximately 36% of Norwegian pregnant women use herbs [16].

There are many reasons why people use herbs and other alternative treatments. It is common to cite a "sense of control" or mental comfort for taking action. Regular items are additionally remembered to be more grounded than drugs that are made. Additionally, conventional medicine is not popular. Patients believe that their physicians:

1. do not respect or pay attention to cultural customs or beliefs;
2. are unwilling to discuss alternative therapies or lack knowledge of them; what's more;
3. put a more prominent accentuation on treating the infection or condition than they do on the patient. Traditional medicine is a quick fix that focuses on curing or treating diseases once they've developed.

Patients frequently believe that conventional medicine has failed them due to chronic or incurable diseases like diabetes, arthritis, and depression [17].

3 Status of Phytomedicines in Developing Countries

The herbal medicine market is growing at an ever-increasing rate. The domestic restorative industry in India generates approximately Rs. 2300 crores, contrasted with the Rs. 2 trillion turnovers of the drug business. 14,500 crores, addressing a development pace of 15%. India is the second-largest producer of castor seeds in the world, producing approximately 1,25,000 tons annually [18]. It has been estimated that 70% of all doctors in France and Germany regularly prescribe herbal medicines, indicating that herbal medicine is used extensively in developed countries as well. According to available records, the herbal medicine market in the countries of the European Union in 1991 was approximately \$6 billion (it may now be over \$20 billion), with Germany accounting for \$3 billion, France for \$1.6 billion, and Italy for \$0.6 billion. In 1996, the US market for herbal medicines was about \$4 billion, and it has since doubled. The commodity of natural rough concentrate and the home-grown drug market in India absolute around \$80 million [19]. Almost 80% of individuals in Africa utilize this medication for their essential considerations. It was estimated that between 30 and 50% of all medicines consumed in China were traditional herbal remedies. In nations like Ghana, Mali, Nigeria, and Zambia, most individuals (around 60%) utilize conventional home-grown drugs as a first line of treatment for jungle fever-related high fever. Around 48% of individuals in Australia, 70% in Canada, 80% in Germany, 42% in the US, 39% in Belgium, and 76% in France utilize conventional and correlative medication something like once. In South Africa, London, and San Francisco, approximately 75% of HIV/AIDS patients use complementary and alternative medicine. Their annual consumption continues to rise significantly, reaching over \$3 billion. Additionally, the Internet has entered the market. The majority of consumers believe that herbal remedies are at least as safe and effective as patented drugs [20–26] (Fig. 1).

4 Formulation Challenges for Herbal Medicine Preparation

There are a plethora of potential side effects, reactions, interactions, nephrotoxicity, hepatotoxicity, and carcinogens that can arise from taking herbal medicines. Contaminated, counterfeit, or adulterated herbal medicines of substandard quality can result in potentially fatal side effects [28]. The fact that the majority of herbal medicines can be obtained without a prescription from a variety of retail and other establishments causes additional issues. As a result, herbal medicines face the same challenges as conventional non-prescription medicines in terms of pharmacovigilance. The World Health Organization (WHO) has issued guidelines as one example of the growing awareness of the need to develop pharmacovigilance practices for herbal medicines [29]. Other disadvantages include drug-herb

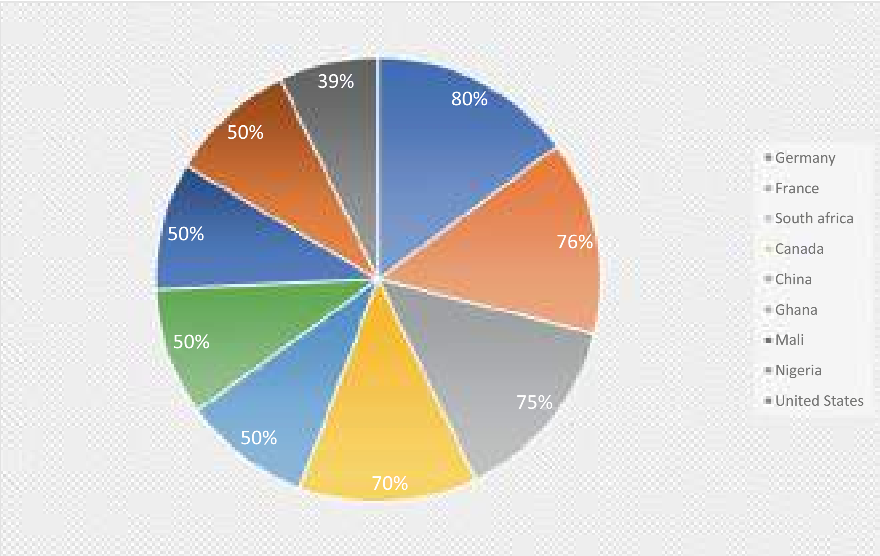

Fig. 1 Consumption of herbal drugs by different countries for healing of disease. (Source: Adapted from Sen and Chakraborty [27])

interactions and quality control. Several herbal products can interact with food, allopathic medicines, or pharmaceuticals, but this information is, unfortunately, lacking for the majority of products. Herbs generally lose their medicinal value after a year of collection; powders made from these herbs last for nearly 6 months, whereas pastes or ointments last for a year [30]. Negative effects of taking herbal medicines include accidentally using the wrong species of plant, adulterating herbal products with other, undeclared medicines, contaminating them with toxic or hazardous substances, overdosing, healthcare providers or consumers misusing herbal medicines, and taking herbal medicines concurrently with other medicines.

The analysis of adverse events associated with the use of herbal medicines is significantly more complex than that of conventional pharmaceuticals, even though the evaluation of the safety of herbal medicines has emerged as a significant concern for consumers, regulatory authorities, and healthcare professionals [31]. There is still a lot of research to be done on the topic of standardizing herbal drugs and formulations in the vast field. The standard books Indian Pharmacopeia, Ayurvedic Pharmacopeia of India, Abundance of India, and Ayurvedic Model all gather monographs that give each of the subtleties to the different tests that should be completed to decide if a rough or planned natural medication follows the guidelines laid. A variety of factors, such as the environment, climate, growth conditions, and storage conditions, influence the potency of a crude drug as well as the formulation prepared using it as a whole, as an extract, or as a constituent isolated. It is essential to standardize not only the primary drug component but also the other included excipients and additives [32]. Numerous pharmaceutical drugs and medicinal herbs are both therapeutic at one dose and toxic at another. The pharmacological or toxicological effects of herbs and drugs may be increased or decreased through interactions. The administration of long-term medications may be complicated by synergistic therapeutic effects. For instance, if taken in conjunction with conventional medications, herbs that are typically used to lower glucose concentrations in diabetic-1 could theoretically lead to hypoglycemia [33].

According to a survey writing study, customary medicine is used by 48.50% of people in Australia, 90% of people in China, 60% of people in Hong Kong, 49% of people in Japan, 60% of people in Nauru, 69% of people in the Republic of Korea, 57.40% of people in the Philippines, 45% of people in Singapore, and half of people in Vietnam [34]. Ayurveda, Kampo, Siddha, traditional Chinese medicine, traditional Korean medicine, and Unani, among other traditional medicine systems, plants are frequently used as ingredients. The discovery of morphine in 1804 by a German pharmacist named Friedrich Serturner marked the beginning of the modern use of drugs.

Around 60% of the medications have been gotten from normal assets since the center of the 1980s. The discovery of chloral hydrate by Justus von Liebig, a professor of chemistry in Giessen (Germany), in 1869 marked the beginning of the era of synthetic drugs [35].

Studies on herbal medicines are now regarded as significant. Typically, herbal medications are administered in the form of pills, decoctions, syrups, tablets, capsules, and other forms. These herbal formulations or raw materials for herbal drugs are physically unstable due to their high moisture content, bacterial and fungal contamination, chemical instability, improper harvesting, storage conditions, and others, Additionally, high moisture content frequently facilitates active component biodegradation. Legitimate drying conditions, considering the deterioration conduct of dynamic constituents, nanoparticle covering of the medication, the utilization of a chelating specialist, definition of emulsion and suspension, and so forth, can diminish these normal reasons for insecurity [36]. When herbal medicine practitioners directly provide products, there is no standardized level of pharmacological knowledge required, and they may not be aware of the knowledge required to safely advise consumers about interactions.

The national systems of the European Union encourage spontaneous reporting of adverse drug reactions. However, this system is known to be prone to underreporting, and the Medicines and Healthcare Products Regulatory Agency in the United Kingdom receives approximately 20,000 yellow card reports annually, but only about 100 herbal reports [37] (Fig. 2, Table 1).

5 Standardization Challenges for Phytomedicines

Nonetheless, normalization can apply to a couple of fixings. Thus, there might in any case be varieties in different fixings, which could affect the item's viability as well as security. Therefore, to ensure the reproducibility of herbal remedy scientific tests,

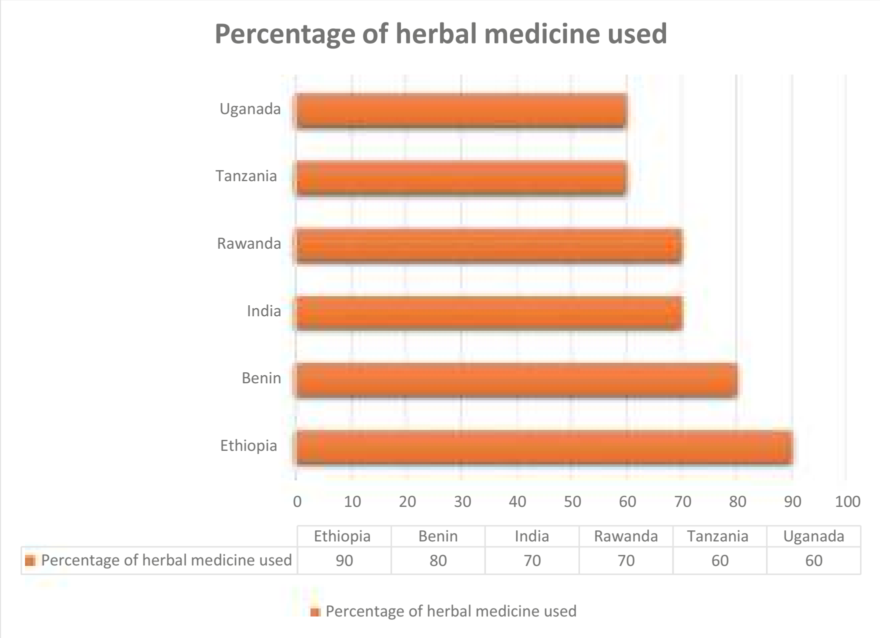

Fig. 2 In some developing nations, herbal medicine is used extensively for primary care. (Source: Author reproduced from WHO data)

Table 1 The Traditional Use of some Herbs as herbal medicine to Treat Common Conditions

S. No.	Name of plants	Common Name	Medicinal uses in some health ailments
1.	*Allium sativum*	Garlic, Lashun	Blood pressure regulation, maintaining the level of cholesterol
2.	*Boerhavia diffusa*	Tarvine, punarnava	Hypertension
3.	*Boswellia serrata*	Indian frankincense	Hypertension
4.	*Butea monosperma*	Palash, dhak	Hypertension
5.	*Cassia Alata*	Candlestick cassia, ringworm cassia	Skin diseases (Pruritis, eczema, ringworm), constipation
6.	*Commiphora mukul*	Guggul	Obesity
7.	*Momordica Charantia*	Karela, bitter gourd	Control sugar level
8.	*Psidium guajava*	Guava, Amrud	Antioxidant, anti-plasmodium, anti-bacterial, anti-inflammatory
9.	*Plumbago zeylanica*	Wild leadwort	Cancer
10.	*Terminalia arjuna*	Arjuna, arjun tree	Cardiovascular diseases

complete product characterization and quality control are required [38]. The dosage formulation, which can influence the bioavailability of the active chemical constituents in the standardized clinical extract, is an important factor to take into account when evaluating herbal supplements and medicines for safety and efficacy [39]. In natural materials, standardization, or the assurance of consistent and dependable ingredients, has been extremely challenging. Plant and herb constituents are extremely complex, and frequently multiple active chemicals with distinct pharmacological and clinical effects are present. This is further complicated by the fact that natural herbs have different chemical compositions and ratios of their constituents depending on many important factors, such as genetic composition, variations in growing conditions, and processing methods (such as harvesting, storage, and manufacturing techniques) [40]. Some herbal medicines are thought to have low associated safety risks, but little is known about how safe they are relative to other medicines. When herbal medicines are used, standard pharmacovigilance tools have additional limitations. Even when a pharmaceutical drug is taken concurrently with an herbal product, adverse effects may still be reported as being caused by the pharmaceutical drug. Inefficient pharmacovigilance procedures always result in a relative underreporting of adverse effects. Numerous authors in Iran, Nigeria, and sub-Saharan Africa have conducted pharmacovigilance studies on herbal medicines [41].

A few of the international authorities and organizations that have begun developing a new strategy to induce and regulate quality control and standardization of botanical medicine include the World Health Organization (WHO), the European Agency for the Evaluation of Medicinal Products, and European Scientific Cooperation of Phytomedicine, the United States Agency for Health Care Policy and Research, the European Pharmacopeia Commission, and the Department of Indian System of Medicine. The Department of Indian System of Medicine is one more. Recent usage of the term “Nutraceutical” refers to foods with health benefits that have been enhanced nutritionally or medicinally. Nutraceuticals include genetically modified or enriched soy products, cereals with added vitamins and minerals, engineered grain, and canola oil that does not contain trans-fatty acids [42]. Numerous nations have added test things of microorganisms, additives, pesticide deposits, weighty metals, and aflatoxin for customary medications and home-grown well-being food sources, and formed their public norms introducing huge cross-country varieties [43].

Standardization and quality control of herbals, as defined by WHO (World health organization) (1996a, b, 1992), is the process of physiochemically evaluating a crude drug. This evaluation covers aspects such as selecting and handling the crude material, evaluating the finished product’s safety, efficacy, and stability, documenting safety and risk based on experience, providing consumer information, and promoting the product [44].

Phytochemical standardization encompasses all available information regarding the chemical components of herbal medicines. As a result, the standardized phytochemical evaluation includes the following:

1. Preliminary testing to determine whether various chemical groups are present.
2. Quantification of the relevant chemical groups, such as total alkaloids, total phenols, total triterpene acids, and total tannins, for instance. Fingerprint profiles are created.
3. Multiple fingerprint profiles based on markers.
4. Determination of significant chemical constituents in numbers [45].

Researchers, manufacturers, and regulatory agencies must use rigorous scientific methods to guarantee the quality and lot-to-lot consistency of traditional herbal products to gain public trust and integrate them into the mainstream of today's healthcare system. The need for standardization and quality control in herbal products can be summed up as follows:

1. Technology and the idea of standardization were very different when traditional medicines were developed.
2. The dynamic process of evolution may have altered the identity of plant material over the past 1000 years.
3. The availability of genuine raw materials has become difficult as a result of commercialization.
4. The effects of time and the environment may have altered the properties of botanicals [46].

The task of quality standardization for herbal medicines (HMs) presents significant obstacles. A major method for quality control of HMs is currently the selection of abundant compounds as markers. However, in many instances, these marker compounds are irrelevant to the bioactivities. As the global demand for herbal medicines (HMs) grows, their quality standardization and control become increasingly important in commercial and clinical settings.

The uniformity of herbal products from batch to batch could be affected by a variety of factors, including variations in growing conditions due to geography and environmental factors. Since phytochemical compounds in HMs are not as refined as in Western drugs, choosing the right marker compounds for quality standardization presents significant difficulties [47]. The most common methods for standardizing herbal medicines are chromatography and spectroscopy, but the herbal system is difficult to analyze due to its complex chemical composition [48]. However, standardization will be more challenging than it would be with synthetic compounds. It is necessary to treat preparations with known and unknown active constituents in different ways. In any case, phytopharmaceuticals must be adequately labeled and characterized for reliable quality and transparency to be achieved. The label should at the very least specify the raw material, extraction method, solvent, ratio of drug to native extract, and quantity of active constituents to facilitate rational phytotherapy [49].

The safety and efficacy of herbal medicines are directly impacted by quality control. When collecting herbal materials, environmental and agricultural practices are important. The WHO has fostered a progression of specialized rules and reports connecting with the security and quality confirmation of restorative plants and natural materials. WHO distributed the ‘Quality Control Strategies for Restorative Plant Materials’, an assortment of suggested test techniques for surveying the personality, immaculateness, and content of therapeutic plant materials to help public research centers participate in drug quality control. The “WHO Guidelines for Assessing the quality of herbal medicines concerning with reference to contaminants and residues” were formulated in 2007 and the “Guidelines on good agricultural and collection practices (GACP) for Medicinal Plants” were published in 2003 [50].

5.1 Current Research on Natural Products

Integrating knowledge of evidence-based herbal medicine into the healthcare curriculum of Western medicine is perhaps the most crucial strategy for the safe use of herbs. The management of herbs may benefit from a few different strategies. They consist of ensuring open communication with patients, educating providers and patients about the potential benefits and risks of herbs, encouraging providers to inquire about their patients’ herb use without being judgmental, and patients should also be cautious when herbal claims are made, and they should only buy herbs from a reputable provider, business, or website [51].

Currently available plant-derived drugs fall into the following main categories: polyketides and other (18%), alkaloids (16%), and terpenes (34%), glycosides (32%), and for instance, digoxin derived from *Digitalis lanata* and used to treat atrial fibrillation, atrial flutter, and heart failure, belongs to the glycoside (cardiac glycoside) class, while artemisinin an antimalarial frontline drug, belongs to the terpene class (sesquiterpene lactone). Lovastatin, preferably isolated and fermented Aspergillus terreus (a hypolipidemic agent used to lower cholesterol), etc. [52].

The following actions are required to set international standards for natural medicines:

Accurate identification is of the utmost importance because medicinal plants that have been incorrectly identified may contain poisonous components. To standardize the manufacturing of Chinese herbal prescriptions, international quality guidelines like Good Sourcing Practice (GSP), Good Agricultural Practice (GAP), Good Laboratory Practice (GLP), and Good Clinical Trial Practice (GCP) are utilized. The processing of herbal products needs to be standardized. Regular items or items got from normal items make up numerous significant medications. From the 1940s to the present, natural products or derivatives make up 48.6% of all cancer drugs registered, and natural products make up 39.1% of all drugs approved by the Food and Drug Administration (FDA). Natural products play a significant role in the process of developing new drugs. More than 200,000 natural metabolites with various bioactive properties demonstrate the significance of natural products in drug discovery. The medicinal properties of between 35,000 and 70,000 plant species have been investigated [53].

6 Strategies for Improvement of Herbal Medicines

The low quality of the drugs is another major problem. Although international standards for drug quality are becoming more stringent, the actual quality of drugs in many nations is not sufficient. Surveys carried out in several developing nations indicate that between 10% and 20% of sampled drugs fail quality control tests. This is partly because there aren't enough resources for drug regulation. It is estimated that only one in three developing nations has fully operational drug regulatory authorities. Another factor is that bad manufacturing practices are not followed, which frequently results in products that are hazardous and even fatal. In the meantime, global quality assurance issues arise from the pharmaceutical trade. Customary medication is additionally impacted by quality issues. In developing nations, traditional medicine provides healthcare for up to 80% of the population. This medication is not only affordable but also widely available and dependable. In developed nations, complementary and alternative medicine has always been viewed as less important than modern Western medicine, but its popularity is currently rising [54].

6.1 Some Strategies for the Advancement of the Natural Medication Industry

By and by, north of 100 million ha of badlands are not just lying inactive, denying the poor valuable open doors for money age yet additionally representing a danger to the environment and climate. These areas can be used to cultivate highly sought-after medicinal herbs. By connecting with bulk buyers, medicinal herb commercial cultivation can be promoted. The following steps are suggested for the successful promotion of the herbal medicine industry in the nation.

1. Establishment of data banks and herbariums, as well as the identification of medicinal plant species.
2. Preservation of restorative spices in their regular living spaces – in situ and in safeguarded regions (ex situ).
3. Choice of prevalent germplasm in light of research facility examination and field studies, for taming and business creation.
4. Normalization of spread and development rehearses for delivering unrivaled quality natural materials, which can be taken on by ranchers.
5. Standardization of the protocols, documentation, and validation of the various medicinal herb cures for various diseases.
6. Intensive research into herbal cures for various diseases, particularly those that are just becoming known.
7. Patenting of traditional methods and plant material. Traditional healers can use facilitation counters to help patent their treatments.
8. The inclusion of herbal medicine as a core course in medical schools that study various medical systems.

9. Using specific prescriptions, social marketing, and widespread awareness to promote the use of various herbal medicines.
10. Assisting traditional healers and Ayurvedic practitioners by sharing knowledge, networking, providing high-quality germplasm, and establishing a connection with farmers for raw material supply.
11. Laying out a conventional linkage between cultivators, mass buyers, and drug enterprises at public and global levels.
12. Changes to government policies to help with herbal medicine research and development and to stop people from using medicinal herbs too much in natural forests [55].

Some of the strategies that are utilized in the process of developing and improving herbal medicines include liposomes, phytosomes, colloidal drug delivery systems (CDDS), super emulsifying drug delivery systems (SEDDS), and other more recent drug delivery system strategies. The development of a novel, safer method for transporting natural active compounds has been significantly aided by CDDS. Numerous natural medications have been delivered through these innovative systems. It was demonstrated that CDDS has a remarkable capacity to increase phytochemical bioavailability and stability. When administered via CDDS, natural active compounds like flavonoids, terpenoids, tannins, and xanthones can cross biological membranes and increase their bioavailability, which results in a better absorption profile. Additionally, CDDS are nontoxic due to their formulation with highly biocompatible raw materials. Since natural excipients have a high-security profile and cause less unfavorable impacts than current drugs, the last medicine is sure to be consented to by patients [56].

The WHO-AFRO's top priority interventions for the first and second decades of African herbal medicine development are as follows:

1. Putting together plans.
2. Upgrading limit.
3. Advancement of research.
4. Promotion of the local production of traditional medicines and medicinal plants.
5. Protection of intellectual property rights and traditional medical knowledge [57].

Three main steps go into making herbal medicine more competitive as part of a management strategy. Strategies like determining the current state of herbal medicine through a literature review (books, journals, and patent documents) and field observation, which were then examined to extract data, are the first steps in the process. Natural medications can be improved from various sources, including HR like workers, volunteers, and ideal interest groups; admittance to brand names, copyrights, and normal assets; Additionally, monetary assets include current cycles like programming frameworks, divisional pecking orders, and representative projects. Physical resources include things like your company's location, facilities, and equipment, such as human resources. Working on Natural Medication's intensity through three primary advances is an administration procedure – the initial step will be figuring out systems like deciding the genuine condition of home-grown medication through a writing survey (books, diaries, patent reports) and field perception, which was then inspected to separate information. Herbal medicines can be improved from a variety of sources, including human resources like employees, volunteers, and target audiences; access to trademarks, copyrights, and natural resources; what's more, current cycles, for example, representative projects, division orders, and programming frameworks are instances of monetary assets. Actual assets, like your organization's area, offices, and hardware, are instances of HR. Each business, association, and individual is impacted by outer powers. It is vital to note and record every one of these variables, whether or not they are related to an open door or danger straightforwardly or in a roundabout way. The term "external factors" typically refers to things over which neither you nor your company has any influence, such as economic trends, as financial trends on a local, national, or international scale; financing, like gifts, the lawmaking body, and different sources; demographics, such as a target audience's age, race, gender, and culture; relations with suppliers and partners; and economic, political, and environmental regulations [58].

Traditional herbal medicine employs the "multi-target/multi-component" strategy because, despite having no analytically defined mechanisms, it has therapeutic effects that have been clinically confirmed thanks to experience and knowledge gained over a long history of treating chronic illnesses. By re-engineering conventional herbal medicine, reverse pharmacology develops novel botanical drugs. Traditional herbal medicine's active ingredients and formulations are studied in reverse pharmacology, and drug candidates or formulations are then developed for preclinical and clinical research [59] (Fig. 3).

7 Prospects of Herbal Medicines in Global Markets

As per WHO (2000, 2002, 2003, and 2005), natural prescriptions and home-grown definitions assume a huge and filling part in worldwide medical services in Asia, Africa, the Americas, Australasia, and Europe. As per WHO gauges (WHO 2000b), 80% of Africans and 70% of Indians utilize natural medication in some structure. "The total of the knowledge, skills, and practices based on the theories, beliefs, and experiences indigenous to different cultures, whether explicable or not, used in the maintenance of health as well as in the prevention, diagnosis, improvement, or treatment of physical and mental illness," according to WHO (2002, 2013) [60]. Amid the COVID-19 crisis, the global market for herbal medicines, which was estimated to be worth US$110.2 billion in 2020, is expected to grow to US $190.4 billion in 2027, growing at a compound annual growth rate of 8.1% from 2020 to 2027. One of the segments examined in the report, herbal pharmaceuticals, is anticipated to reach US$84.1 billion by the conclusion of the analysis period and grow at a CAGR of 8.6%. Growth in the Herbal Functional Foods segment is adjusted to a revised 7.9% CAGR for the next 7 years, taking into account the ongoing recovery from the pandemic [61].

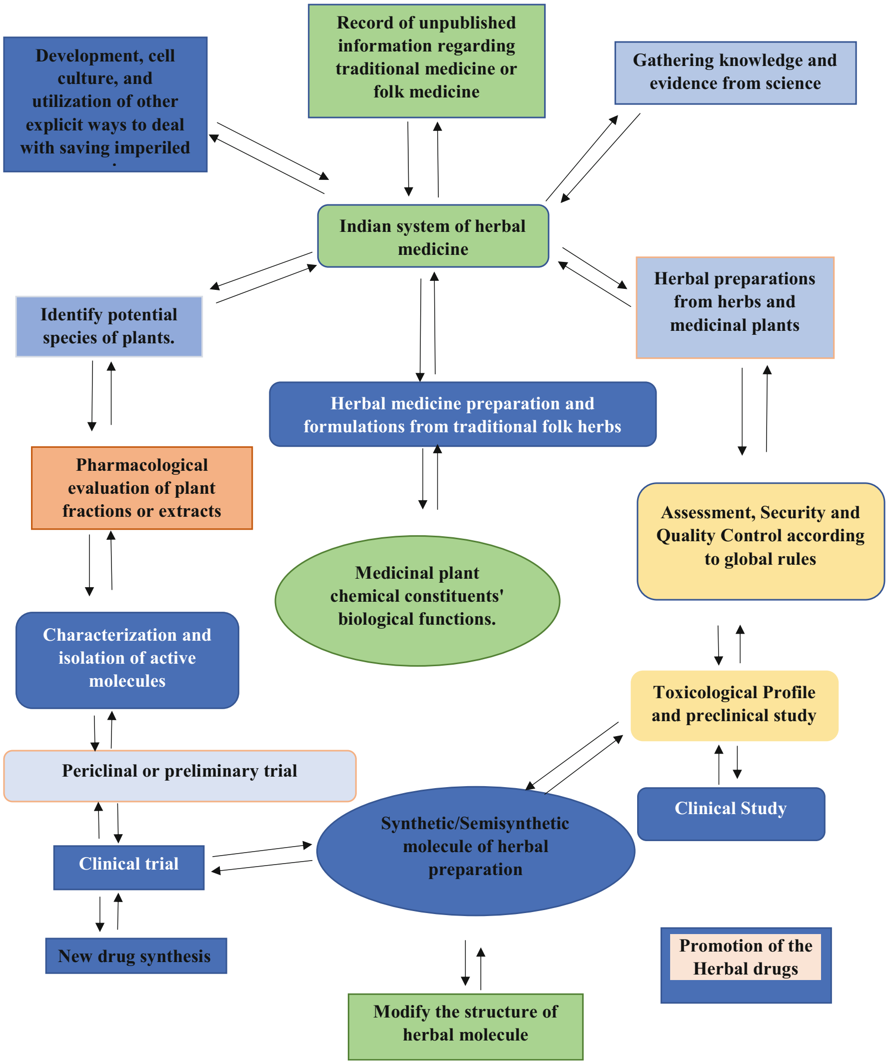

Fig. 3 Strategies for the advancement and development of traditional herbal medicine and its integration into modern medicine. (Source: Adapted from Sen and Chakraborty [27])

Worldwide, the use of herbal medicines has significantly increased. In recent decades, concerted efforts to globalize China's botanical medicines have led to a boom in the herbal industry. Mahuang and ginkgo, two Chinese herbal remedies, have successfully entered the international market, and their use is on the rise all over the world. Herbal and dietary supplements (HDS) make up a $180 billion market in the United States, and 18.9% of people reported using them in 2004. HDS is purchased by American consumers annually for approximately $6 billion. It has been estimated that the global market for herbal medicine, which includes herbal products and raw materials, grows at a rate of 5% to 15% annually. Botanical products account for approximately 30% of international drug sales. It is anticipated that the global herbal drug market will reach USD 5 trillion by 2050 [62].

India is the world's largest exporter, surpassing China, with approximately 13% of all exports. With 50% of exports, the United States is the primary market for Indian medicinal plants. The EXIM study found that 880 species of medicinal plants are traded in the country. There are approximately 42 imported species and 48 exported species among these. Over 8000 species of medicinal plants are grown in India, according to another survey by the Ministry of Environment and Forests of the Government of India. Seventy percent of these species are found in the tropical forests of the Western and Eastern Ghats. In its report for 1997, the Export-Import Bank of India estimates that India's trade in medicinal plants is worth $5.5 billion, an enormous increase [63].

According to WHO, traditional medicine has received renewed global attention and interest over the past decade. Traditional medicine is used for about 40% of all healthcare in China. Seventy-one percent of the population in Chile and 40% in Colombia have used such medication. Ayurveda and medicinal plants are used by 65% of the rural population in India to meet their primary healthcare requirements. Traditional, complementary, and alternative medicines are growing in popularity in developed nations. For instance, 48% of people in Australia, 31% in Belgium, 70% in Canada, 49% in France, and 42% in the United States have taken such medications at least once. Even though herbal products are subject to regulation or registration in nearly 70 nations, only 25 countries reported having a national policy for traditional medicine as of the year 2000. It is common to refer to traditional medicine as "complementary," "alternative," or "non-conventional" medicine in some nations where it has not been integrated into the national healthcare system. Due to the widespread misperception that "natural" means "safe," many consumers use traditional medicine for self-care. It's possible that they don't know about herbal medicines' safe use or potential side effects. Either there is no safety monitoring system at all or herbal medicines are not included in the safety monitoring system that is in place. Cases of improper use of herbal preparations have been reported due to a lack of quality control and consumer use. For instance, in 1996, an herbal remedy that contained the toxic plant *Aristolochia fangchi* rather than *Stephania tetrandra* or Magnolia officinalis led to the kidney failure of more than 50 people in Belgium [64].

Consumers now have much greater access to herbal products from anywhere in the world thanks to the development of the internet and the growing emphasis on a global economy. Also, businesses are using websites to boost sales, and the majority of them are more concerned with making a profit than protecting the public. While many of these websites may assert that their products are pure, standardized, safe, and effective, these claims are impossible to verify. With the growing use of medicinal plants and herbal remedies, public interest in natural therapies has skyrocketed in industrialized nations over the past few decades. Traditional medicines come in many different forms and have developed in response to a wide range of cultural, climatic, geographical, and even philosophical contexts. There are significant obstacles to overcome when evaluating these products and ensuring their safety and effectiveness through registration and regulation [65].

During the Middle Ages, trade along important terrestrial or maritime routes was linked to the first historical trend toward the globalization of herbal and traditional medicines. Global product trade is common today. Traditional Chinese medicine (TCM) and other herbal and traditional medicines are becoming increasingly popular worldwide. When it comes to trying to get into different markets for herbal medicines, businesses face a lot of obstacles. They must adhere to various laws, accept diverse requirements, and accept diverse standards. Pharmaceutical companies must therefore create distinct dossiers for the same products to present them to various national authorities.

To create the ideal regulatory environments for herbal and traditional medicines, international communication between the scientific community and regulators is required [66].

It would appear that one of the most crucial steps in implementing targeted marketing, market segmentation, has been overlooked. It is possible to identify customer attribution and select the appropriate sectors for targeting the market, establishing an appropriate market position, achieving a competitive advantage by creating distinct competitors, and increasing profitability based on effective market segmentation. Additionally, these market agents ought to discover methods for more precisely and effectively identifying customer behavior to identify, formulate, and implement their marketing strategies. The study's objective was to determine the appropriate factors for segmenting the herbal medicine market [67] (Fig. 4).

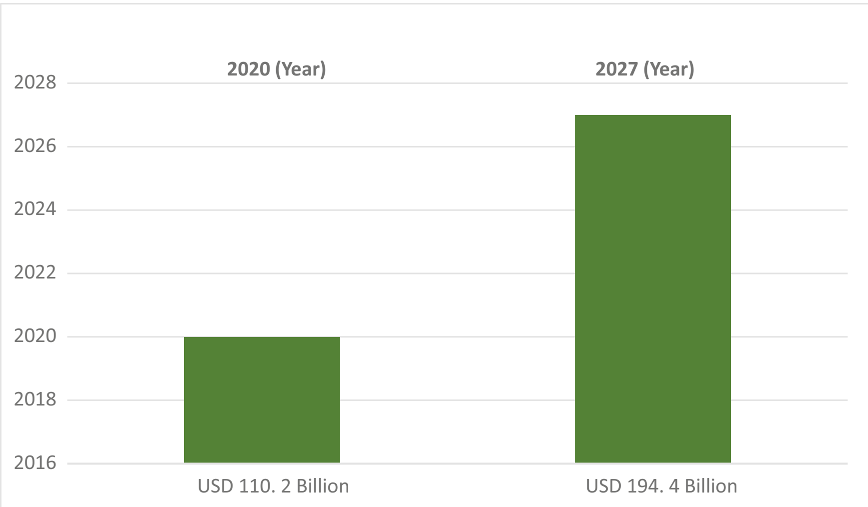

Fig. 4 Estimated growth in herbal medicine industry. (Source: Modified from Research and Markets [68])

8 Herbal Medicine Commercialization Challenges for Global Market

A major obstacle is verifying the herbal materials used and evaluating contradictory toxicological, epidemiological, and other data objectively. These significant issues persist. Pharmacovigilance Analyzing "drug" interactions and comprehending why harmful additives work. Requirements with clinical preliminaries and individuals accessible Normalization, Security and adequacy evaluation, The executives inside risk ranges, correspondence of vulnerability, Pharmacological, Toxicological, and Clinical documentation [69].

It also appears that medicinal herbs and their products have very diverse value chains. Surprisingly, very few studies have examined the value chain of medicinal herbs and herbal products, despite the volume of trade. The World Health Organization (WHO) has estimated that there is a $14 billion annual demand for medicinal plants (2006), and this demand is growing at a rate of 15–25% annually. The World Health Organization predicts that trade will reach up to $5 trillion by 2050 (Fig. 4). The global herbal medicine value chain approach is a useful analytical tool for comprehending the consequences of these shifting internal trade patterns in herbal products and medicinal herbs. Biopiracy, illegal collection, a lengthy gestational period before maturity, unresponsive permit/license systems, dispersed producers, and a lack of linkages among chain actors are the primary sources of risks to the commercialization of medicinal plants through cultivation (domestication).

According to many types of research and collected data by researchers, the commercialization of herbal drugs for the market has many obstacles:

1. Different requirements from the law.
2. Restricted market.
3. Issues with raw material standardization.
4. The limited or absence of regulations [70].

Regulatory and legislative processes for herbal medicines vary from country to country. This is due, in large part, to cultural factors as well as the fact that herbal remedies are rarely studied scientifically. As a result, few herbal preparations have been evaluated for safety and effectiveness. To assist national regulatory authorities, scientific organizations, and manufacturers in this particular field, the WHO has published guidelines that define fundamental criteria for evaluating the quality, safety, and efficacy of herbal medicines [71]. There are frequently several obstacles that must be overcome before traditional or herbal medicines can be regulated in various regions of the world. Challenges that are prevalent in many nations include regulatory status, evaluation of safety and efficacy, quality control, safety monitoring, and inadequate knowledge of traditional, complementary, and herbal medicines within national drug regulatory authorities. Even though the worldwide exchange of restorative plants is developing, the advantages to agricultural countries, especially cultivators and makers, are still low. This is because the poor collectors of medicinal plants from the wild lack organization and networking, as well as intermediaries.

This raises transaction costs, which are limited by the increasing stringency of health and safety regulations in developed nations' main markets [72].

The actual issues begin with the commercialization and industrial production of herbal plants, and bio-entrepreneurial skills take center stage. The bioproduct can be sold if there is already a market for it and there is a shortage of it, or if it is valuable enough or there are enough of it. The three nations that currently account for the majority of the commercialization of bioresources and medicinal plants are Germany, the United States, and Hong Kong. Altogether, 12 countries are answerable for 80% of the exchange that happens around the world. The second issue is industrial production or commercial harvesting. Due to the ongoing development of biotechnology processes and the high cost of chemical synthesis, Paclitaxel or Taxol, a well-known cancer drug that has been produced by Bristol Meyers Squibb (BMS) since 1992 and has recently been produced by other companies after BMS' exclusivity ended, still heavily relies on plant-based production [73]. One more example of how precious our lives are in tropical regions all over the world is the fact that tropical plants have produced more than 50 major drugs. Worldwide rural associations have progressively seen the general target of food security as a connection to the more extensive objective of further developing occupations throughout the last 10 years or something like that. However, as the globalization and commercialization processes progress, so do the number of partners and the information they produce. Lack of data on information sources, ad-hoc access to data, and incompatibility of a great deal of data that is accessible by hundreds of organizations, government agencies, and individuals in a dispersed manner are additional obstacles in information management [74]. The importance of the trade in traditional medicines to consumers' overall well-being and the improvement of healers' and/or traders' livelihoods is growing. However, this trade's unregulated activities jeopardize harvesting's long-term viability and, as a result, the availability of sufficient ethnomedicinal plant resources [75].

A marketing strategy is the foundation for any drug development beyond a certain point. A pharmaceutical company must decide whether to spend millions of dollars on advanced pharmacological studies and eventually clinical trials at a crucial point in the development process. When making such a decision, there are numerous factors to take into account. One of these is whether the medication will be able to generate approximately $500 million in sales within 2–3 years of its release [76].

The creation and implementation of HM regulations are difficult in many nations. Regulations, evaluation of safety and efficacy, quality control, and a lack of understanding of TM/CAM among national drug regulatory authorities are to blame for these difficulties. The WHO TM Strategy was developed with four primary goals to address these issues: forming policies; boosting quality, efficiency, and safety; determining access; and promoting sound use [77]. The use of HM and its legal status differ greatly from country to country. HM in India is governed by the Drugs and Cosmetics Act of 1940 (Amendment), the Department of AYUSH, the Central Council of Indian Medicine Act, and the Research Councils Indian Council of Medical Research (ICMR) and Council of Scientific and Industrial Research (CSIR). The Drug Controller General of India (DCGI) has set guidelines for the use of botanicals in allopathy (Table 2).

Table 2 A list of some Indian medicinal plants that are important to the market [12, 53]

S.No.	Name of Medicinal Plants	Biological Name	Family of the plants
1.	Makoi	*Solanum nigrum*	Solanaceae
2.	Punarnava	*Boerhavia diffusa*	Nyctaginaceae
3	Brahmi	*Bacopa monnieri*	Plantaginaceae
4.	Brahmi booti	*Centella asiatica*	Apiaceae
5.	Tulsi	*Ocimum sanctum*	Lamiaceae
6.	Jatamansi	*Nardostachys grandiflor*	Caprifoliaceae
7.	Shatavari	*Asparagus racemosus*	Asparagaceae
8.	Ashwagandha	*Withania somnifera*	Solanaceae
9.	Giloe	*Tinospora cordifolia*	Menispermacea
10.	Mulethi	*Glycyrrhiza glabra*	Fabaceae
11.	Sarpagandha	*Rauvolfia serpentina*	Apocynaceae

9 Future Prospects of Herbal Medicine

In light of their growing use and rapidly expanding market in both developed and developing nations, policymakers, health professionals, and the general public are increasingly raising concerns about the safety, efficacy, quality, availability, preservation, and future development issues of herbal products. Proof of natural items' security, viability, and quality has likewise expanded popularity among people in general. Due to the high value they bring to healthcare as well as the commercial advantages they provide, extensive research on herbal medicines is required to alleviate these concerns and satisfy public demand. Fortunately, there are already a lot of phytochemical and pharmacological studies on herbal medicines and medicinal plants all over the world. Attempts are being made to isolate and identify the active chemical constituents of these medicines and medicinal plants to support claims that they are safe and effective. More often than not, it has been demonstrated that natural cures don't need logical help because the vast majority of them contain significant substance compounds and carry out the asserted role. In addition, randomized clinical trials have shown that many herbal medicines have strong scientific support.

It is abundantly clear that, regardless of how significant the demands and concerns of policymakers, medical professionals, and the general public may be, they will never stop the growing use of herbal medicines. As a consequence of this, herbal medicine-based Traditional Medicine (TM) practices are still prevalent in developing nations, whereas CAM (complementary, alternative, or CAM) practices are rapidly expanding in developed nations. As specialists produce increasingly more logical proof of their quality, adequacy, and well-being, this overall pattern of expanding and broad utilization of natural meds is probably going to proceed.

However, just like with allopathic medicines, established rules and regulations should be used to control the production, sale, and use of herbal medicines to ensure their quality and safety. In any case, the nature of home-grown items sold isn't ensured, and guidelines and enrollment of home-grown prescriptions are not well-developed in many countries. Thus, endeavors ought to be made to raise public mindfulness about the dangers and advantages of utilizing natural meds and to get home-grown drugs under legitimate control in all nations where they are utilized for clinical and restorative purposes.

When utilized accurately, home-grown prescriptions of "guaranteed quality" make certain to affect clients and lower their gamble. In addition, it is important to keep in mind that herbal products and remedies, just like allopathic medicines, can have negative effects. In addition, they will probably have negative effects. Additionally, the use of adulterated herbal ingredients and formulations that are not appropriate may facilitate the production of low-quality, harmful, or even dangerous herbal medicines. To deliver home-grown medications, it is important to comply with GMP guidelines stringently.

With this caution in mind, it is safe to say that herbal medicines have a bright future and may one day be better alternatives to allopathic medicines made of synthetic chemicals or even replace them.

10 Conclusion

For the treatment of both laid out and arising infections, conventional prescriptions are presently the essential strategy for drug disclosure. Because they could be used as herbal remedies or for the isolation of compounds that could be patentable, researchers in Tanzania and other locations continue to find them appealing. Nevertheless, it is essential to guarantee that the information is utilized for both financial gain and the enhancement of our populace's health. There is a need to establish the expertise necessary for the creation of traditional medicines for cultivation to become feasible and, as a result, contribute to the reduction of poverty. Furthermore, conscious endeavors ought to be made to energize neighborhood modern creation of conventional and natural meds. Through administrative rules for quality control, normalization, and the assembling system, existing information on home-grown drugs should be checked and reported. Chemical consistency throughout all manufacturing processes extraction, standardization, quality control, quality assurance, stability, shelf life, and purity are essential to ensuring that medicines are safe and effective. Because herbal medicines are an essential component of traditional healing systems, it is necessary to preserve, promote, and further develop the knowledge base necessary to guarantee the identity, purity, and quality of botanical ingredients. Pharmacopeias assume an essential part in these cycles. Clinical evidence of the therapeutic effects of herbal products has led to the study of numerous additional herbs for their therapeutic, either curative or preventative, roles. Future research should focus on the isolation and identification of specific active substances from plant extracts because this could reveal compounds with greater therapeutic value. Modern and traditional knowledge can be combined to create novel medications that heal wounds and have fewer undesirable side effects. In created countries, natural-based conventional medication has acquired prevalence as of late and is probably going to fill in ubiquity before long. This method performs better than the allopathic method because it is preventative. Utilizing these plants sustainably, conserving them, and studying reproductive biology, phytochemistry, and pharmacological validation are all necessary because the increased use of herbs has a direct impact on the collection of raw materials. Another crucial requirement for quality control is the standardization of chemical fingerprinting (TLC, HPLC).

Herbal medicine will continue to serve as a broad foundation for drug discovery alongside bioactive lead compounds, active fractions, and active formulations. The strategy by which new single mixtures and dynamic parts can be created as clinical competitors will be given by profoundly effective bioactivity-coordinated fractionation and separation, structure portrayal, simple amalgamation, and unthinking investigations. To confirm and guarantee the safety and efficacy of prescriptions for multiple components and single herbs, clinical trials and dependable pharmacological and toxicological methods and standards are required. Using organic and compound markers, present-day innovation should be utilized to lay out quality controls and normalize natural items. In conclusion, Herbal ought to employ three strategies for discovering and developing novel drugs: formulations, pure active principals, and active fractions that have been tested or improved.

microorganisms in certain parts of the body culminating in diverse medical problems. The use of herbal medicine to cure and manage these microbial diseases requires a certain amount of training (formal or informal) for efficiency and success. Improper composition of herbal mixtures may end up containing microbes like *Staphylococcus* species, *Escherichia coli*, *Pseudomonas aeruginosa*, and others that can exacerbate the initial illness. The training and practice rely heavily on available plant resources of the locale as well as local knowledge and cultural practices and the indigenous people. The bioactive substances found in medicinal plants have been linked to their therapeutic and microbial load reduction or eliminating effects. Depending on their species, regional distribution, and prevailing environmental conditions, different metabolites are known to be present in plants. Most diseases brought on by microorganisms may be grouped into one of four categories: bacteria, parasites, viruses, and fungi. Some of the common diseases that are treatable by plant extracts or herbal medicine include malaria, trichomoniasis, fascioliasis, helminthiasis, ascariasis, trichinellosis, dracunculiasis, gonorrhoea, syphilis, cholera, tuberculosis, pneumonia, food poisoning, tooth decay and gingival inflammation, typhoid fever, salmonellosis, skin infections, blood poisoning, and urinary tract infections (bacteria). Some of the causative agents are resistant to conventional antibiotics from modern medicine like methicillin-resistant *Staphylococcus aureus*, and *Candida albicans*, and vancomycin-resistant *Enterococcus* species. These microorganisms and the disease they cause are easily treated with plant extracts or herbal remedies. However, there is a need for research to focus on the identification, isolation, and purification of bioactive compounds in plant extracts and herbal remedies to encourage sustainable utilization and production in commercial quantities. Furthermore, the procedures involved in the investigation of raw resources, the production of herbal treatments, branding, and marketing, as well as sustainable utilization, need to be standardized and most importantly, require aseptic techniques to minimize microbial contamination of the raw materials and finished products.

1 Introduction

Microbes are everywhere, and many tend to thrive in extreme environments. Different groups of microbes have been reported in many human foods and food sources [1–16] and in different environmental matrices, including water [17–24], sediment [25], and air [26]. Many of these microbes are useful and have been implicated in food safety and quality; whereas some are used industrially in the production of useful products and metabolites. Quite a number of them are pathogenic and have the tendency to cause disease conditions in humans that are exposed to infectious agents. The diseases caused by microbes are often grouped into viruses, bacteria, parasites, and fungi.

In our world today, products of plant origin have become reliable sources for medications used to combat diverse microbial infections and are considered vital in the management of diseases caused by microbes [21]. Medicinal plants have been used for centuries in traditional medicine for the management of various diseases, including those caused by microbes. The efficacy of plant-based medications in treating microbial infections, especially in traditional medicine, is well known and has been reported by researchers from Africa [27–31], Asia [32], South America [33], and North America [34]. Plant-based products have always been sought out across the globe in the maintenance of health and treatment of diseases irrespective of culture and ethnicity thanks to their easy access and low cost [35–38]. In our world today, despite the availability of modern medicine, herbal medicines are still relied on. In different parts of the world, for example, Nigeria, China, Pakistan, and the United States, it is estimated that about 50–70% of their population depend on medicinal plants [39]. Even in an industrialized country like Japan, the demand for plant-based medicines in comparison to modern medicines has increased significantly [39].

Phytochemical substances with antimicrobial properties released during plants' biochemical reactions such as free radicals, flavonoids, reducing compounds, alkaloids, tannins, saponins, anthraquinones, terpenoids, and phlobatinins are now being used for combating various microbial infections [40]. The active compounds present in these plants have antimicrobial properties that can inhibit the growth of microorganisms, including bacteria, viruses, and fungi. The use of medicinal plants as a form of alternative medicine has gained popularity in recent years due to the increasing resistance of microorganisms to conventional antibiotics [41–58] and control of insects [59–64]. In this section, we will discuss medicinal plants that have been traditionally used for the management of diseases caused by bacteria, fungi, and viruses and the scientific evidence supporting their use [27, 28, 32, 34, 65–67]. There are enormous research needs around the use of medicinal plants in the management and treatment of microbial infectious diseases.

This chapter focuses on the plants, plant extracts, and herbal remedies used to address diseases caused by diverse microorganisms, including fungi, bacteria, viruses, and parasites, and the research gaps that are pertinent to the promotion of the practice. The chapter first presents an overview of herbal medicine practices and then proceeds to herbal medicine used in the management of diseases caused by microorganisms from parasitic, fungal, bacterial, and viral standpoints. Then, the chapter focuses on the treatment of antibiotic-resistant microbes and herbal medicine research needs specifically for medicinal plants and herbal remedies used for addressing microorganism-caused diseases.

2 Overview of Herbal Medicine Practices

Traditional medicine is viewed as a combination of different skills, practices, and knowledge based on beliefs and experiences used by different cultures in diagnosing, preventing, and eliminating [68]. Traditional medical knowledge may be passed on from one generation to the next in the form of stories (orally), by spiritual ancestors, and in recent times in writing [69]. Herbal medicine, also called phytomedicine or phytotherapy, is a core part of traditional medicine and involves the use of medicinal plants, their water or solvent extracts, oils, gums, resins, or exudates made from the plant parts, and other natural substances as sources of drugs for the treatment, prevention, cure of diseases, as well as maintenance of health and general well-being [70, 71]. According to the World Health Organization, herbal medicine comprises herbs, herbal preparations, and finished herbal products that contain plant materials like flowers, roots, berries, leaves bark, etc., or their extracts as active ingredients used for therapeutic interventions in humans as well as animals [72]. Throughout history people have used plants and various plant parts like leaves, stems, bark, and roots for healing and curing diseases and health promotion with varying levels of success [73].

Documented records of medicinal plants used in herbal formulations date back over 5000 years to the Sumerians with archaeological records even indicating an earlier use of medicinal plants thousands of years before [70]. Ancient records as well as archaeological data have shown the use of medicinal plants in ancient Egypt, Greece, China, and India [74–77]. In the last century, there have been massive developments and production of chemically synthesized medicines which have changed the healthcare system in most parts of the world, but about 70–80% of the world's population, especially developing countries, still rely on herbal medicine as their primary healthcare option. In Africa, up to 90% and, in India, up to 70% of the population rely on herbal medicine to meet their healthcare needs [73]. The use of herbal medicine is not only limited to developing countries as even industrialized countries have in recent years expanded their use of ethnobotanicals. About 38% of adults and 12% of children were found to be using some form of herbal medicine [78]. The use of herbal medicine is now widely embraced in many developed countries and is now becoming mainstream as these remedies are now available in drug stores, supermarkets, and even food stores [79]. There has been a growing interest in alternative medicine and the use of natural products as therapeutic agents, especially plant products, in the last 20 years [70]. There are many reasons why herbal medicine use has become widespread and now has an increasing appeal to the world's population. In some countries, herbal medicine is more accessible as a large percentage of the world's population does not have access to conventional allopathic medicine [80]. Herbal medicine generally also more closely corresponds to the patient's ideology as folk medicine, and ecological awareness suggests that these products are natural, harmless, and non-toxic compared with the side/adverse effects associated with synthetic medicine [73]. This is not necessarily true as when these medicines are taken with other herbs or over-the-counter medicine which is sometimes the case, they can lose their efficacy and even become harmful [81]. It is generally also more affordable when compared with the high cost of modern drugs. Herbal medicine also satisfies the desire for more personalized healthcare and establishes a movement towards self-medication [82]. Some people also have the erroneous belief that herbal products are superior to manufactured conventional medicine because of the presence of multiple active compounds that can provide effects that may not be achievable by a single compound [73]. They also claim that herbal products are highly effective against their health challenges [79]. Herbal products are generally used for the promotion of health and as therapy for chronic conditions rather than fatal conditions; however, where conventional medicine has failed or is ineffective such as advanced cancer, herbal medicine is employed [73]. Recent technological advancements leading to improvements in the quality, efficacy, and safety of herbal medicines have also contributed to the recent resurgence of public interest in herbal remedies [79]. Because of the greater access to health information, some patients believe that their doctor has not properly identified and diagnosed their problems and thus feel that herbal medicines are the next options to try [79].

Herbals and herbal preparations can be processed and administered in several ways, the most common being in the form of liquids either as teas or diluted plant extracts such as infusions, decoctions, macerations, tinctures, elixirs, extracts, etc. [83]. Herbal products can also be utilized as whole herbs, syrups, oils (essential oils), capsules, tablets, salves, rubes, etc. [73]. Regardless of how herbal products are processed and used, it does provide a significant healthcare service whether or not allopathic medicine is available [84]. The general perception by the population that herbal remedies are safe, harmless, or non-toxic, and devoid of side effects is very wrong as some herbs have been shown to produce a wide array of undesirable side/adverse effects, some even life-threatening under certain circumstances. A study by Ekor et al. [85] revealed that the herbal formula Yoyo 'Cleanser' bitters, a very popular herbal product marketed and sold in Nigeria, was associated with elevated levels of liver enzymes, resulting in hypokalaemia and arrhythmias. Another report by John et al. [86] revealed that some herbal blood tonics sold in Nigeria caused splenic enlargement in 10% of the recipient mice and even a case of lung tumour. Rietjens et al. [87] also reported on several Chinese herbal medicines implicated in cases of poisoning. Herbal products may also be contaminated and adulterated, and because most times there are no standardized set doses, it could lead to herb–drug or herb–herb interactions which could be fatal sometimes [73].

In most countries, herbal medicines are not standardized and do not follow mandatory safety or toxicology testing as they lack the machinery to regulate the manufacturing, packaging, and distribution of these products, leading to substandard products which could be potential hazards to the consumers [82]. Also, the increasingly growing market for herbal products could drive the over-harvesting of these medicinal plants, leading to the destruction of biodiversity and extinction of these plants [88–91]. Medicinal plants and ethnobotanicals have been used throughout history for the promotion of health and the treatment of disease. Although herbal products do not meet the accepted scientific standard for drugs, it is, however, very important to note that most herbal products from history have become the basis for today's modern medicine and contribute largely to the commercial conventional drugs manufactured today [92]. Examples include quinine isolated from the bark of a cinchona tree previously used for shivering but now used for treating malaria [93]. Aspirin, found in the bark of the willow tree, was previously used as a herbal product for fevers, pain, and inflammation in ancient times but is now used for different conditions, including rheumatic fever, heart attacks, blood clots, pain, fever, pericarditis, amongst others [94]. Digitalis from the plant *Digitalis* is a group of herbaceous plants commonly called foxgloves used previously by herbalists but now employed in conventional medicine for the treatment of heart conditions [95]. Opium from the plant *Papaver somniferum is* used as a herbal product for anaesthetics, suppositories, medical poultices, etc., but now conventionally used as morphine for pain and also as a recreational drug (heroin) [96]. Artemisinin from the plant *Artemisia annua* used in Chinese traditional medicine is now used commercially for the treatment of malaria due to *Plasmodium falciparum* for which its founder obtained a Nobel Prize in 2015 [97]. Herbal medicine is the oldest and still the most widely used system of medicine in our world today, and although the mechanisms underlying these plants derived remedies are still not well understood, the successful use of herbal medicine in the treatment and prevention of infectious diseases shows that many plants have the potential to mitigate bacterial fungal viral and even parasitic infections as will be discussed shortly [98].

3 Herbal Medicines Used in the Treatment and Management of Diseases Caused by Microorganisms

Phytotherapy is one if not the oldest system employed for the treatment of infectious diseases and has been employed to treat even contemporary infectious diseases like human immunodeficiency virus (HIV) and cancer with varying levels of success [99]. In recent years, the search and use of drugs obtained from plants and natural sources have been on the rise with scientists combing the earth for different potent

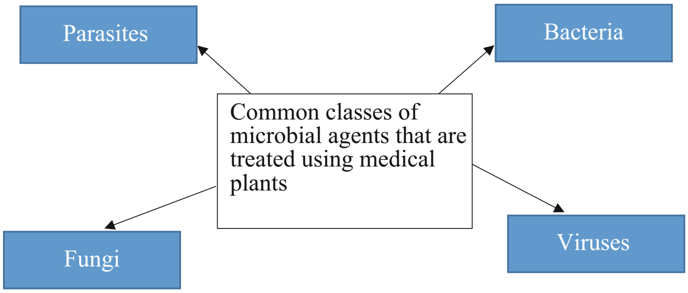

Fig. 1 Classes of infectious agents that are commonly treated using medicinal plants

phytochemicals that can be developed into medicine for the prevention and treatment of various diseases [100]. The use of herbal medicine seems to be universal across cultures, but the types of plants and methods applied may vary. When compared with conventional allopathic medicine, herbal medicine is easily and freely available, especially in West Africa (Nigeria), where 80–90% of the population still rely on herbal medicine as their basic healthcare system [101]. The diseases caused by microbes are often classified into four classes (Fig. 1).

3.1 Herbal Medicine and Medicinal Plants Used for the Treatment of Parasitic Infections

Infections caused by endoparasites like nematodes, protozoa, trematodes, etc., can affect more than 20–30% of the population because they cannot be prevented by vaccination. Most of the parasites have become drug resistant over the years, and the production of new bioactive antiparasitic drugs has not been a priority because these types of infection are mostly found in poor underdeveloped countries. This has resulted in the increased need for plant extracts and herbal formulations which can interfere with membrane structure, signal transduction, and DNA alkylation and intercalation of these parasites. Several plants have shown promising effects towards the management and treatment of diseases caused by parasites (Table 1).

3.2 Herbal Medicine and Medicinal Plants Used for the Treatment of Bacterial Infections

Medicinal plants have been used for centuries as a source of natural cures for various ailments, including infections caused by bacteria [114, 115]. Bacterial infections are a common problem that affects a wide range of individuals, and traditional societies have used plant-based remedies to treat them. The use of medicinal plants in the treatment of bacterial infections has been the subject of many studies, and the aim has been to identify new drugs to combat them, as well as provide new treatment options for patients who are resistant to conventional antibiotics.

Table 1 Medicinal plants and their formulations that are used to control parasitic infections

Plant species (or herbal products)	Parts used	Herbal preparation	Disease used against	Causative agent	Reference
Azadirachta indica	Leaves	Boiled in water to create an infusion which is then taken	Malaria	*Plasmodium falciparum*	[102]
Allium cepa	Bulb	Aqueous extract	Trichomoniasis	*Trichomonas vaginalis*	[103]
Allium sativum	Bulb	Decoction	Fascioliasis	*Fasciola gigantica*	[104]
Carica papaya	Seeds	Aqueous extract		*Ascaris lumbricoides* and *Ascaridia galli*	[105]
Chenopodium ambrosioides	Twigs, leaves, and flowers	Boiled in water to create an infusion which is then taken	Helminthiasis	Intestinal parasites (roundworm, pinworms, *Giardia lamblia*)	[106]
Aristolochia trilobata	Leaves	Boiled in water to create an infusion which is then taken or soaked in alcohol (rum) and taken as shots	Helminthiasis	Intestinal parasites (roundworm, pinworms, *Giardia lamblia*)	[106]
Vermicin (a mixture of *Olea europaea*, *Thymus vulgaris*, *Hydrastis canadensis Berberis aristata*, *Inulae radix*, and *Caryophylli flos*)	Leaves, rhizome, flower buds	Syrup	Helminthiasis	Intestinal parasites (roundworm, pinworms, *Giardia lamblia*)	[98]

Giardinophyt contains *Thymus vulgaris, Chrysanthemum vulgare, Anethum graveolens, Eugenia caryophyllata,* and propolis cera	Leaves, seeds	Ethyl alcohol extract	Helminthiasis	Intestinal parasites (*Giardia*, pinworms, *Ascaris*, etc.)	[98]
Cucurbita pepo and *Punica granatum*	Seeds and peels	Ethanolic and aqueous extract	Ascariasis	*Ascaridia galli*	[107]
Nigella sativa	Seeds	Alcoholic extract	Trichomoniasis	*Trichomonas vaginalis*	[108]
Artemisia vulgaris and *Artemisia absinthium*	Leaves	Methanolic extracts	Trichinellosis	*Trichinella spiralis*	[109]
Vernonia amygdalina	Leaves	Hot water extract	Helminthiasis	Intestinal parasites (*Giardia*, pinworms, *Ascaris*, etc.)	[110]
Jatropha curcas	Roots, leaves	Poultice with salts for roots and decoction for leaves	Dracunculiasis	Guinea worm	[111]
Combretum mucronatum	Leaves	Decoction	Dracunculiasis Helminthiases Enterobiasis	Guinea worm, hookworm, and pinworm	[112]
Triphyophyllum peltatum, Ancistrocladus abbreviatus, and *Ancistrocladus barteri*	Root and stem bark	Dichloromethane extract	Malaria	*Plasmodium berghei*	[113]

Echinacea is an example of a medicinal plant used in the treatment of bacterial, fungal, and viral infections [114–116]. As a herb, Echinacea has been traditionally used to boost the immune system and to treat a variety of infections, including bacterial infections [117]. Studies have shown that the antibacterial properties of Echinacea are due to the presence of active secondary metabolites such as alkamides (from *Echinacea*), glycoproteins, caffeic acid derivatives, and polysaccharides [115]. Extracts of Echinacea obtained from ultrasound-assisted extraction and other classical methods have been reported to effectively inhibit the growth of various bacteria species, including *Staphylococcus aureus*, *Streptococcus pyogenes*, *Listeria monocytogenes, Haemophilus influenza, Pseudomonas aeruginosa,* and *Escherichia coli* [115, 118].

Ginger is another medicinal plant with antimicrobial properties. Its active compounds are shogaol and gingerol, which have been found to have antimicrobial activity. A research study published in the *Journal of Sharif Medical and Dental College*, Lahore, Pakistan, found that gingerol, the active compound in ginger, had strong antimicrobial activity against several types of bacteria, including *Staphylococcus aureus* and *Escherichia coli* [119]. This suggests that ginger may be an effective alternative treatment option for bacterial infections. Another example of a plant with medicinal value used in treating a variety of bacterial infections is turmeric. Turmeric is commonly used in Indian and Middle Eastern cuisine as a spice and colouring agent [120, 121]. Traditionally, it has been used to treat a variety of ailments, including bacterial infections. Curcumin is the active compound found in turmeric and is known to be an antioxidant and possesses antibacterial properties, including antiplatelet, cholesterol-lowering, anti-inflammatory, and antifungal properties [120]. According to research studies, curcumin can effectively inhibit the growth of various species of bacteria, including *Helicobacter pylori* (which is the common cause of peptic ulcers) and *Staphylococcus aureus* [120, 121].

Manuka honey is also another traditionally important plant-based remedy for treating bacterial infections. Manuka honey is obtained from the nectar of the Manuka tree found in New Zealand [122, 123]. Extensive research studies on Manuka honey have revealed that Manuka honey possesses a significantly high antioxidant capacity which contributes to its antibacterial properties [124]. According to Swift et al. [123], high levels of a stable antimicrobial compound called methylglyoxal present in Manuka honey make it potent against a variety of bacterial species, including *Staphylococcus aureus* resistant to Methicillin, commonly known as Methicillin-resistant *Staphylococcus aureus* (MRSA), and *Clostridium difficile*, a nosocomial agent responsible for a significant percentage of hospital-acquired infections [122], by effectively inhibiting their growth.

Oregano is another medicinal plant that contains phytochemical compounds such as thymol and carvacrol, which are effective against bacterial infections [125]. According to Lu et al. [125], oregano oil was effective against multi-drug-resistant clinical isolates, including *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, and methicillin-resistant *Staphylococcus aureus*. Thymol and carvacrol, the active compounds in thyme, have been found to have antimicrobial properties.

Medicines of plant origin have been used for centuries to cure bacterial infections and remain the preferred treatment option in many traditional societies. *Echinacea*, turmeric, ginger, and Manuka honey are examples of plant-based medicines with antibacterial properties that are effective in treating bacterial infections. Several plants have shown promising effects towards the management and treatment of diseases caused by bacteria (Table 2).

3.3 Medicinal Plants Used in the Treatment of Fungal Diseases

Fungal infections are a universal problem that affects a wide range of individuals, from healthy persons to those with compromised immune systems. The use of medicinal plants in the treatment of fungal infections has a lengthy history, and many traditional societies rely on them as remedies for treating fungal infections. An example of a medicinal plant used in the treatment of fungal infections is garlic. Traditionally, garlic has been used to treat a variety of fungal infections, such as aspergillosis and candidiasis. Researchers have shown that garlic has antifungal properties and can effectively inhibit the growth of various fungal species [144–146]. According to Dikasso et al. [144], garlic juice was observed to have a more efficient antifungal effect on pathogenic moulds, dermatophytes, and yeasts in comparison to conventional antifungal medications. The major antimicrobial components of garlic are allicin, organosulfur compounds, and diallyl sulphides [146].

Tea tree oil is also a good example of a medicinal plant used in the treatment of fungal infections. It is obtained from the leaves of the *Melaleuca alternifolia* plant commonly found in Australia and has traditionally been used for treating fungal infections [147]. Studies have shown that the active antimicrobial component of tea tree oil Terpinene-4-ol has antibacterial activity against *Propionibacterium acnes* as well as antifungal activity. Terpinene-4-ol was seen to effectively inhibit the growth of various fungal species, including *Candida albicans*, which is a common cause of candidiasis [147]. Another example is the use of neem, a tree native to India. Traditionally, it has been used to treat diverse fungal infections, including athlete's foot and ringworm. According to Singh et al. [148], salicylic acids and phenolic acids such as caffeic, vanillic, o-coumaric, and cinnamic that are extracted by high-performance liquid chromatography (HPLC) showed high antifungal activity in vitro. Neem and its antifungal components have been reported to effectively inhibit the growth of various fungal species, including *Trichophyton mentagrophytes*, which is a common cause of ringworm [149]. Medicinal plants have been relied on for centuries to treat fungal infections, and for many traditional societies, they remain an alternative to conventional cures for treating fungal infections. Garlic, tea tree oil, and neem are examples of medicinal plants with antifungal properties that are effective in the treatment of fungal infections.

Table 2 Medicinal plants and their formulations that are used to control bacterial infections

Plant species (or herbal products)	Parts used	Herbal preparation	Disease used against	Causative agent	Reference
Gloriosa superba	Roots	Root infusions	Gonorrhoea Syphilis	*Neisseria gonorrhoeae*	[126, 127]
Terminalia chebula	Fruit	Methanolic extract	Cholera	*Vibrio cholera*	[128]
Anogeissus leiocarpa	Stem and root barks	Methanolic extracts	Tuberculosis	*Mycobacterium tuberculosis*	[129]
Urtica urens	Whole plant	Aqueous extract	Pneumonia	*Streptococcus pneumoniae*	[130]
Ribes nigrum and *Hippophae rhamnoides*	Fruits	Fruit juices	Tooth decay and gingival inflammation	*Streptococcus mitis*, *Staphylococcus aureus*, and *Pseudomonas aeruginosa*	[131]
Calluna vulgaris L. and *Vaccinium vitis-idaea*	Leaves and flowers	Water, ethanol and ethyl acetate extract	Urinary tract infection	*Escherichia coli*, *Enterococcus faecalis*, and *Proteus vulgaris*	[132]
Punica granatum	Fruit	Methanolic extracts	Ulcer	*Helicobacter pylori*	[133]
Harrisonia perforata	Twigs	Methanolic extract	Plague	*Streptococcus mutans*	[134]
Psidium guajava	Leaves	Essential oil, acetone, methanol, and hexane extracts	Food poisoning	*Bacillus cereus*, *Enterobacter aerogenes*, and *Pseudomonas fluorescens*	[135]
Cannabis sativa	Leaves	Oils and aqueous and alcoholic extracts	Skin infections, blood poisoning, and shock	Methicillin-resistant *Staphylococcus aureus*	[136]
Sideritis italica	Flowers and leaves	Essential oil and acetone extracts	Ulcer	*Helicobacter pylori*	[137]
Barringtonia asiatica	Leaves	The aqueous extract and essential oil	Typhoid fever Salmonellosis	*Salmonella typhi*	[138]
Juglans regia L.	Bark	Ether extract	Oral infections	*Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Escherichia coli*	[139]

(continued)

Table 2 (continued)

Plant species (or herbal products)	Parts used	Herbal preparation	Disease used against	Causative agent	Reference
Guatteria multivenia	Root	Ethanolic extract	Skin infections, blood poisoning, and shock	Methicillin-resistant *Staphylococcus aureus*	[140]
Acanthus montanus	Root	Aqueous root extract made by hot water maceration of the root powder	Boils (furuncles)	*Staphylococcus aureus*	[141]
Amaranthus spinosus	Leaves	Ethanolic extract	Diarrhoea	*Staphylococcus aureus* and *Escherichia coli*	[142]
Bridelia ferruginea	Bark	Aqueous and ethanolic extracts	Urinary tract infections, diarrhoea, and food poisoning	*S. aureus*, *S. epidermidis*, *E. coli*, and *Proteus vulgaris*	[143]

3.4 Medicinal Plants Used in the Treatment of Viral Diseases

For centuries, medicinal plants have been used as a source of natural remedies for various ailments, including viral infections. In today's world, viral infections have become common among a wide range of individuals, thereby prompting the use of plant-based remedies to treat them. The use of medicinal plants in treating viral infections has been the subject of many studies to identify new drug formulations to combat viral infections, as well as make available new treatment options for patients who are resistant to conventional antiviral drugs [150–154].

Andrographis paniculata is one of the medicinal plants used in the treatment of viral infections. *A. paniculata* is a herbaceous plant traditionally used in Ayurvedic and Chinese medicine to treat diverse viral infections [150]. *A. paniculata* possesses active compounds such as andrographolide and neoandrographolide which have been found to have antiviral properties. Aqueous extracts of *A. paniculata* using 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) method and SYBR green quantitative real-time polymerase chain reaction (PCR) method have been reported to be potent against the dengue-2 virus responsible for dengue fever [150]. Significant antiviral activity of andrographolide and dihydro andrographolide, both secondary metabolites of *A. paniculata,* has also been reported against the highly pathogenic influenza A viruses and avian influenza (H5N1) virus. Research studies have shown that *Andrographis paniculata* can effectively inhibit the replication of various viruses by inhibiting neuraminidase activity, thereby reducing the symptoms experienced during upper respiratory tract infections [150, 151]. Another study carried out by Shi et al. [152] using silver nanoparticles biologically synthesized from herbs, including *A. paniculata*, showed an inhibition of the replication process of the Chikungunya virus, thereby suggesting an alternative cure for Chikungunya virus infection. Nitrobenzoxadiazole-conjugated andrographolide (Andro-NBD), a derivative of andrographolide, has been reported to suppress protease activities of Severe Acute Respiratory Syndrome Coronavirus (SARS-CoV) which suggests a possible alternative for combating COVID-19 infection [152]. Other derivatives of andrographolide with quinoline moiety have been shown to protect against Zika virus infection [153] while others have been reported to prevent HIV infections [154].

Elderberry is another example of a plant-based cure for viral infections [155]. Elderberry has been traditionally used for centuries to treat a variety of upper respiratory tract and viral infections, including influenza and the common cold [155]. Recent studies have shown that extracts of elderberry effectively inhibited the replication of influenza viruses, and feline immunodeficiency virus (FIV). Black elderberry fruit extract has also been reported to exhibit antiviral activity against human coronavirus HCoV-NL63 in vitro [155]. Reductions in the severity of symptoms and duration of infections caused by these viruses were also recorded during the use of elderberry extracts [155]. The active compounds found in elderberry include phenolic acid components and flavonoids [155]. Another example is the use of licorice root, *Glycyrrhiza glabra,* to treat viral infections [156]. Traditionally, licorice root has been used in Ayurvedic and Chinese medicine to treat a variety of viral infections. Fukuchi et al. [157] reported high antiviral activity of alkaline extracts of licorice roots and their possible application as an HIV agent [157]. The researchers also identified significant potency of water extracts of licorice roots rich in flavonoids in the treatment of herpes simplex virus [157]. The active compounds found in licorice root include glycyrrhizin and liquiritin [157]. *Andrographis paniculata*, elderberry, and licorice root are examples of plant-based treatment options which are effective in the treatment of viral infections.

4 Medicinal Plants Used in the Treatment of Antibiotic-Resistant Microbial Infections

Antibiotic-resistant microbes, also known as superbugs [158], have become a growing problem worldwide, and the search for new treatment options for antibiotic-resistant microbial infections has become increasingly important. One potential solution is the use of medicinal plants as a source of natural remedies for these infections [159].

An example of a plant-based medicine used in the treatment and management of antibiotic-resistant bacterial infections is goldenseal (*Hydrastis canadensis*) native to Appalachia [160, 161]. The rhizome and root of goldenseal have been traditionally used to treat a variety of infections, including bacterial infections [160, 161]. Studies have shown that goldenseal contains a strong antioxidant called berberine [160] which has strong antibacterial and antifungal properties, and in synergy can effectively inhibit the proliferation of various antibiotic-resistant bacteria species, including *Pseudomonas aeruginosa*, *Escherichia coli* [162], methicillin-resistant *Staphylococcus aureus* (MRSA), and vancomycin-resistant *Enterococcus* sp. (VRE) [161]. The main bioactive compounds in goldenseal are alkaloids – berberine, canadine, and hydrastine [160, 161].

Although allicin in garlic is traditionally used to combat bacterial infections, it has also been reported to be potent against antibiotic-resistant infections. A study by Saripilli and Pikkala [163] showed that garlic was as potent as ciprofloxacin in combating antibiotic resistance. Its strong antibacterial properties can effectively inhibit the growth of various antibiotic-resistant bacteria species, including *Escherichia coli* and methicillin-resistant *Staphylococcus aureus* (MRSA) [158]. Another example is the use of neem (*Azadirachta indica*), commonly referred to as 'village pharmacy' [148]. *Azadirachta indica* has been traditionally used to treat a variety of bacterial infections, including antibiotic-resistant infections. Studies have shown that neem leaf extract and neem oil have antibacterial properties and can effectively inhibit the growth of various antibiotic-resistant bacteria species, including MRSA and *Candida albicans* [164].

With rising cases of resistance to antibiotics, the need for phytochemical substances with medicinal value cannot be overemphasized. New approaches to combating microbial infection have become essential, and medicinal plants such as garlic, goldenseal, and neem are examples of medicinal plants with antimicrobial properties that are effective against antibiotic-resistant bacterial infections [40].

5 Research Needs in Herbal Medicine and Medicinal Plants Used in the Management and Treatment of Diseases Caused by Microorganisms

The research needs in the field of herbal medicines are very many, but this may be balanced out by the potential benefits derived from these products as evidenced by the use by large populations, especially in underdeveloped countries. The area of research needs includes evaluation of safety and efficacy, quality control, regulatory and safety monitoring, and education and training of health authorities and control agencies [165]. In industrialized and civilized countries, standardization and consistent quality control of herbal medicinal products are considered one of the major bottlenecks affecting the overall acceptance of herbal formulations [166]. Considering the increasing popularity of medicinal plants, there is a need for extensive research on herbal medicine to ascertain their toxic level and overall safety. Some key research areas requiring attention include a thorough analysis of side effects associated with herbal medicines and ways of bypassing their negative interactions with other prescription drugs [166]. It is worth noting that some herbal plant species bear the same name which necessitates a taxonomic and systematic review to avoid their inappropriate usage during the treatment of microbial diseases [35].

Another issue affecting research on herbal medicine is the lack of quality clinical trials, and in some cases, the research is either irreproducible or bereft of methodology or interpretation. Safe dosage standards concerning factors such as body weight and drug interactions are a key aspect of herbal medicine research requiring attention, especially during clinical trials. This could be resolved through aggressive testing to determine the safest and most effective doses. Research is needed to ensure the identification of the exact compounds and bioactive elements in these herbal formulations so that they can be purified to use for specific diseases as against using the whole plant [42, 43]. A single medicinal plant may contain hundreds of bioactive compounds, and when used in combination with other herbs or natural products, the herbal product may contain several hundreds of bioactive molecules which makes it difficult to determine what exact component is responsible for the therapeutic effects seen when used and what components may be responsible for adverse effects. This is well observed and described in conventional medicine where there is only one active ingredient, and the benefits and side effects are well elucidated [73]. Research is also needed on the use of whole herbs or whether the use of extracted bioactive compounds is better. The isolation and identification of each active ingredient from each herb in the product may be very costly, time-consuming, and not cost-effective for the manufacturers of these products, but with new emerging techniques like genomic testing and chemical fingerprinting definitive authentication and standardization of herbal products may be achieved [73]. Standardization in the preparation methods of herbal products is still very lacking and needs more research. There is a lack of adequate or accepted research methodology for the evaluation of herbal medicine. Methods for preparing these medicines need to be accurate and reproducible to ensure the release of the same herbal products irrespective of the brands and manufacturers [72, 167].

Research is needed to ensure the safety of herbal products as there is generally a lack of systematic approaches to assess the safety and effectiveness of herbal products. The general notion that herbal products are safe or non-toxic is very untrue and misleading as several products and medicinal plants have caused toxicity to humans and animals. For example, aristolochic acids found in Asian medicinal plants and occasionally in slimming products have been shown to have genotoxicity, which is hard to repair and persists for years in the DNA [168]. Another herb, *Ephedra sinica,* which is routinely used for respiratory conditions and is now marketed as a weight loss dietary supplement, is now associated with cardiovascular and central nervous system adverse effects [169] and also hepatotoxicity [170]. The evaluation of the safety of these herbal products is also complicated by the different processing techniques, route of administration, dosage, compatibility with other herbs or conventional medicine, and even the geographical origin of the plant as well as environmental factors in the area of harvest [171]. Research must be carried out to properly identify and authenticate the names of medicinal plants to avoid confusion and potential risks. More manufacturers rely on common names and not the universal binomial taxonomic identifier which can lead to toxicity. For example, the herb *Heliotropium europaeum* (heliotrope), which contains hepatotoxic compounds, could be confused with *Valeriana officinalis* (garden heliotrope), known to contain sedative and muscle relaxant properties. National health authorities and control agencies should work collaboratively with botanists, phytochemists, pharmacologists, and other major stakeholders to establish published databases with the taxonomic identifiers of medicinal plants to avoid misidentification and mislabelling which can potentially lead to toxicity [79]. Also, the issue of herb-to-herb interaction and herb-to-drug interactions needs to be analysed and awareness increased to avoid toxic adverse reactions. Concurrent use of herbs with drugs could mimic or magnify or oppose the effects of conventional drugs. For example, bleeding is seen when warfarin is combined with garlic (*Allium sativum*), don quai (*Angelica sinensis*), ginkgo (*Ginkgo biloba*), or danshen (*Salvia miltiorrhiza*), mania is seen in depressed patients who mix antidepressants and *Panax ginseng*, increased risk of hypertension when tricyclic antidepressants are mixed with yohimbine (*Pausinystalia yohimbe*), amongst other adverse effects [172]. Herb-to-herb interactions have also been observed with turnip juice capable of abolishing the geno protective effect of ginseng [173].

There needs to be increased education, training, and expertise within the national health authorities and control agencies like the Food and Drug Administration (FDA), Standard Organization of Nigeria (SON), National Agency for Food and Drug Administration (NAFDAC). These bodies should work collaboratively to ensure that the necessary regulations and legal and ethical mechanisms are established for the promotion and maintenance of policies bordering the safety, efficacy, and authenticity of herbal products [165]. A common regulatory framework should be established across different countries to ensure that the use, efficacy, and safety of herbal products are not influenced by the traditional experiences available in a particular location [174]. More control should be given to these controlling bodies to ensure the safety and efficacy of herbal products before they are released into the market. The manufacturers should be made to follow specific guidelines and good manufacturing practices to ensure the quality of herbal products and also made to obtain licences stating the source of herbs used, potency, other medicinal ingredients and recommended use, and other vital information [175]. There is also a general lack of data on the composition and quality of most herbal products as a result of the lack of policies or governmental requirements. Regulatory policies on herbal products need to be standardized across the globe and the relevant authorities in each country need to be proactive and put appropriate measures in place to ensure public health and that the herbal medicines approved for sale are of good quality [79].

It is imperative to determine that herbal products will be made from plants from a uniform genetic source with records of the exact species and cultivar to ensure manufacturers do not use different species of medicinal plants that could potentially be toxic. Herbs should be grown under specific conditions because the environment (temperature, drought, pollutants, etc.) can affect the phytochemical components of these herbs. Techniques like biochemical profiling should be employed to ensure that a consistent plant is always used to produce herbal medicine [73]. When it comes to herbal medicine there is a general lack of research data. Therefore, another important area of research is the production of scientific evidence concerning health claims by carrying out clinical trials. Questions of efficacy will always remain except adequate amounts of scientific evidence are produced and accumulated from experimental animal models and then human trials [176]. Ethically this would be very hard to accomplish; therefore, there is a need to find and document new predictor biomarkers and detectable signs of early cellular degeneration that relate to health and disease outcomes [73].

In many developing countries, traditional medicine, of which herbal medicine is a core part, is the only system of healthcare available or affordable. Therefore, as the global use of herbal medicine continues to increase and many more herbal products are released into the market, many more public health concerns and research needs will be identified accordingly. Although many herbal medicines have great potential, the lack of substantial scientific evidence of their efficacy is lacking and many of them even remain untested; therefore, more research is needed in this area. As with other conventional medicines, herbal medicines must be covered by a country's regulatory framework to ensure their safety, quality, and efficacy, and the consumers should be provided with science-based information on the dosage, origin of ingredients, antagonist, efficacy, and adverse effects of herbal medicine [73, 79]. Other bottlenecks closely associated with research on herbal medicines include the improper selection of patients' batches, inconsistency in the duration of treatments, inadequate number of patients during clinical trials making it difficult to reach a statistical significance, and inability to set up adequate placebos due to the taste and aroma of herbal formulations [177].

6 Conclusion

Approximately 80% of the world's population currently uses herbal medicine for addressing diverse medical problems, either directly or indirectly. A large proportion of these medical problems may be linked to microbial infection or appearance in diverse parts of the body. Herbal remedies or plant extracts have been widely documented to be effective against these microorganisms' caused diseases but many lack supporting experimental or research data and are considered as claims. There is a need for research validation as well as the enumeration of the mechanism of action for these herbal remedies. Research techniques, tools and approaches in herbal medicine need to adopt contemporary practices. Plant extracts or herbal remedies prepared from plants will continue to be used for addressing viral, fungal, bacterial, and parasitic medical problems in humans. Diverse plants and plant parts (used either alone or in combination) are formulated mostly using local strategies and consumed in varying dosage are adopted to address specific microorganism-caused diseases. Considering that the majority of herbal medicine used for addressing diverse illnesses including those caused by microorganisms is within the Global South where modern or conventional healthcare is rare, it would be hugely beneficial to support the practice with modern research and techniques. There is a need for increased education, training, and expertise within the national and international health authorities and control agencies about the efficacy of herbal remedies and plant extracts in treating and managing microorganism-caused medical issues. Other pertinent research areas needing urgent attention are the discovery, enactment, and purification of the bioactive ingredient to be employed in large-scale production of the ingredients. Together, these practices can help address the lack of substantial evidence to support the efficacy and use of herbal medicine. Herbal medicine used for treating and managing diseases caused by microorganisms needs to be aligned with modern medicine in terms of incorporating clinical trials as well as standardization and quality control during the formulation phase of herbal remedies. Also, training and education can help reduce cases of microbial contamination of plant extracts and herbal remedies used for addressing diseases caused by microorganisms.

Contents

Abstract

Plants play a key role in humans by providing uncountable ecosystem services and have sophisticated traditional medicinal importance. Food, flavors, clothing, fragrances, and shelters are major benefits of plant ecosystem. Medicinal plants gained wider recognition due to varying herbal products but these are disappearing at alarming rate. Climate change also affects medicinal resources and their conservation is of prime concern today. However, conservation strategies and resource management techniques minimize medicinal plant depletions at greater extent. Good farming practices and sustainable use solutions are

progress by resource management techniques. Whereas conservation strategies promote both in situ and ex situ methods, which are further geared by sustainable usage of medicinal plant resources. Protecting medicinal plant resources are highly advocated in updated and reframed policy. Also, an awareness of the importance of medicinal plant and its sustainable usage is recommended from local to global platforms. Constructive policies and plans are needed for conserving and sustainable usage of important medicinal plants, which having herbal and ethnobotanical importance. Therefore, healthy medicinal plants maximize species diversity and intensity of many ecosystem services, which maintains soil, food, and climate security at the global scale. Further, a transdisciplinary approach is needed for targeting production, conservation, and sustainable usage of medicinal resources, which strengthen socioecological and economic paradigm. Moreover, scientific research and future recommendation are necessitated for defending medicinal losses as threatened and species rarity in the safeguards of humans which maintains environmental sustainability and ecological stability.

1 Introduction

Medicinal plants represent plant system cherish with medicinal properties which needs for biodiversity and human society. These plants consist of important compounds, which are used in the drug industry [1]. Plant parts such as leaves, roots, stem bark, fruits, flower, or even whole plants can be used for medicines [2, 3]. These plant parts contain different active compounds, which induce therapeutic effects directly or indirectly and are used as medicinal agents [4]. The production and storage of active compounds in the plant body have certain physiological effects on different organisms [5]. Raw plant materials are needed by humans for meeting medicinal needs, which further maintains healthy ecosystem [6]. Medicinal plants perform synergistic actions due to presence of certain active compounds that are used for treatment of many diseases [7, 8]. It plays key significant role in people's life by ensuring medicinal security to them. Medicinal plants used in society since time immemorial which maintains wellbeing and minimize illness including epidemics. However, peoples treated themselves by medicinal uses due to their interests and knowledge of medicinal plants [9].

Medicinal plants have been used in healthcare since ancient times in many countries such as India, Egypt, China, and Greece [10]. Plants are used as drugs, aromatic agents, and disinfectant due to the presence of active compounds [11, 12]. Cosmetic and pharmaceutical products used more than one-tenth of the plant species for different medicinal uses. However, medicinal plants population and its distribution are not uniform across the world [13, 14]. Further, demands of medicinal plants increased by 8–15% per year^{-1} in the countries of Asia, North America, and Europe [15]. This is due to increasing importance and utility of medicinal plants throughout the world. But their overuses cause decline in medicinal resources, which affects biodiversity and ecosystem services. Similarly, written documents on traditional knowledge systems are scarce and vanishing day by day due to negligence of importance and services. Overexploitation and unsustainable usage of medicinal plants exert pressure on natural forests, which affects the overall health of the ecosystem and its productivity [16, 17]. Overexploitation and indiscriminate uses of medicinal plants not only affects regeneration, distribution, and diversity but also affects livelihood of forest fringe peoples [18, 19]. However, plants-based herbal medicine gained wide recognition due to fewer side effects compared to allopathic medicines, which satisfies the human population by providing cures for many diseases. Thus, medicinal plants ensure healthy human life with greater biodiversity, which maintains ecosystem health and environmental sustainability. Managing medicinal resources and its conservation through many scientific strategies (in situ and ex situ conservation) manage quality and quantity of medicinal products for people and industrial uses [20]. Medicinal plant can be conserved through in situ and ex situ practices. National parks (NPs), biosphere reserves (BRs), joint forest management (JFM), and some medicinal plant conservation areas are included under in situ conservation. Many herbal and botanical gardens, seed bank, cryopreservation, gene banks, different tissue culture repositories, etc., are included under ex situ conservation techniques [21, 22]. Proper harvesting and sustainable uses of medicinal plant along with its good market structure augment its productivity and medicinal quality. Construction policies and good governance are needed for harvesting, marketing, and conservation of different medicinal resources across the world. Moreover, a scientific research and future recommendation are necessitated for defending medicinal losses as threatened and species rarity in the safeguards of humans.

This chapter discusses medicinal plant diversity, the importance of traditional medicinal plants, and its related ecosystem services. Phytochemicals of medicinal plants and its relevant medicinal properties and antimicrobial affects are also discussed. Threatened medicinal plant resources due to climate change and unsustainable harvesting practices along with their conservation strategies are included in this chapter. Many constraints and challenges of medicinal plant resources are included, which can be overcome through better conservation techniques, constructive policies, and scientific research.

2 Medicinal Plant Diversity: Global Context

Medicinal plant's population, diversity and its distribution are uneven globally [23]. Drugs and health products used approximately one-tenth of the total plant species. China and India stand in topmost position in medicinal plants usage. Approx. 11146.0 and 7500 number of species were used as medicinal plants in

China and India, respectively, which was followed by other countries [23, 24]. Most of these plants are threatened species among the medicinal plants [13]. These threatened species exist due to resource destruction and genetic erosion of certain medicinal plants, which are listed under IUCN status [25]. Approximately 38,660 numbers of medicinal plants exist in Asian continent of which 78.0 number of medicinal plant species grown and commercialized whereas 26.0 species was accounted by China [26, 27]. Therefore, an extraction and cultivation of medicinal plants popularized and becomes integral part of many countries such as India, China, Bangladesh, Pakistan, Indonesia, and Myanmar [28, 29].

Medicinal plant diversity and its importance gained wider recognition globally due to higher medicinal usage which often represented as "Medicinal or Botanical garden" [30]. Globally, 9500 number of species (of total 48,655 number of documented plant species) represented ethno-botanical importance [31, 32]. Similarly, modern system of medicines and indigenous health practices used approx. 7500 number of medicinal plant species [32]. Diversified medicinal resources have greater medicinal significance, which cures many diseases and ailments in the world [33]. For example, *Withania somnifera*, *Phyllanthus emblica*, *Asparagus racemosus,* and *Tinospora cordifolia* have greater potential to deprive the negative effects of COVID-19 and SARS-CoV-2 [34]. So, many plants have been shown to inhibit both gramme-positive and gramme-negative organisms, thereby being an effective source of antimicrobials [17, 35–37]. Similarly, the characteristics and significances of organic farming-based medicinal plants are depicted in Fig. 1 [38–40].

3 Traditional Medicinal Plants: Drugs of Tomorrow

From Asia, traditional medicinal practices have been popularized in the world since time immemorial. *Ayurveda* practices in Himalayas, Kampo practices in the region of Japan, *Jamu* practices in the region of Indonesia, Sowa Rigpa practices in the region of in Bhutan, traditional Chinese medicine practices in the region of China, and Thai medicine practices in the region of in Thailand are critical examples of traditional medicinal practices in the world [41, 42]. However, traditional herbal medicines are also based on practicing different indigenous knowledge systems. These traditional systems guided people in using different medicinal plants resources, which play greater role in managing the lifestyle of human beings [43, 44]. Similarly, use and practice of medicinal plant *Rosmarinus officinalis* (rosemary) can be quantified based on past documentary proof and different statistical and linguistic approaches [45].

Plants usage can be determined by different cultural practices [46]. Medicinal plants are traditionally used in different cultures due to its diversified groups in nature [47, 48]. Diversion and shifting of traditional medicine practices to modern medicine system are an interesting part of research today [49, 50]. Therefore, ethnobotany science gained wider recognition and ensures intrinsic the relationship between plants and local communities [41]. Indigenous plant species play greater role in traditional knowledge protection and biodiversity conservation. Traditional

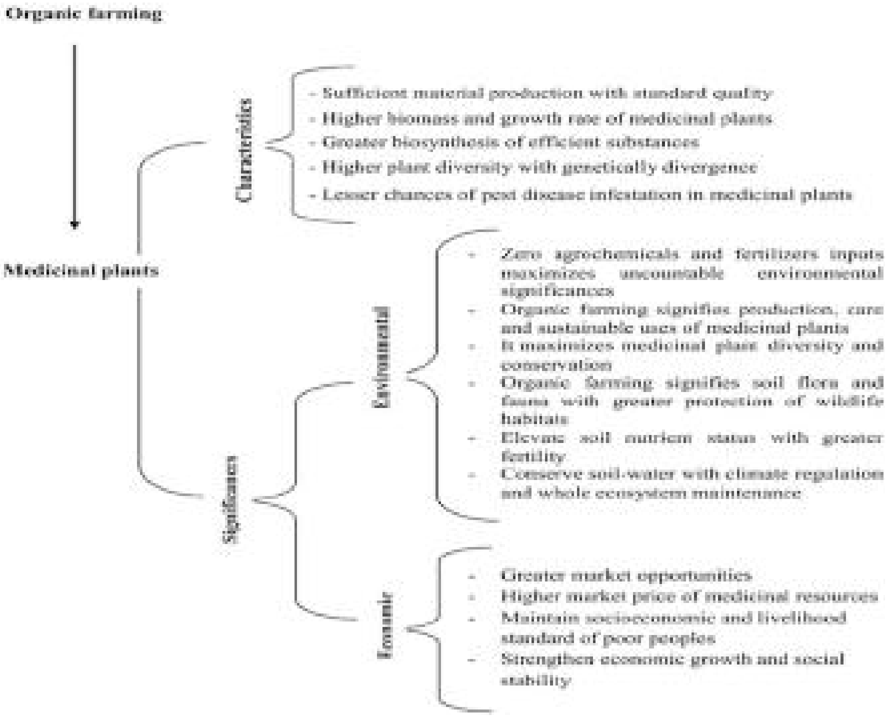

Fig. 1 The characteristics and significances of organic farming-based medicinal plants [38–40]

medicines promote PMC (primary health care)-based system and sustains approximately 70% of global populations [51]. Industrialized countries directly or indirectly depend on different medicinal plants for generating pharmaceutical products [52]. However, both India and China are top listed Asian countries that play greater role in production and management of medicinal plants. Approximately 50 and 45% of both export and earning of medicinal plants are contributed by Asian countries [53].

4 Medicinal Plants for Ecosystem Services

Plants play an important role in delivery of uncountable ecosystem services. However, medicinal plants are listed as provisioning ecosystem services under the United Nations MEA (*Millennium Ecosystem Assessment*) of 2005. Diversified medicinal plants ensure variety of ecosystem services, which maintains ecological stability and environmental services. Medicinal plants cure many diseases and ailments for better lifestyle of humans. Humans, animals, and other living organisms depend on plants for their life sustenance. However, herbal medicines promise good health of ecosystem and maintain health security for greater sustainability. A variety of plants are to treat many different diseases for better human and animal life. These plants not only provide shelters to many organisms but also maintain soil health and ecosystem productivity. Medicinal plants ensure soil fertility by providing nutrient loads in unfertile soils. Soil enrichment, water regulation, health security by disease management, greater plant productivity, and climate change mitigation are key ecosystem services provided by medicinal plants. However, medicinal plants also mitigate C footprints and climate change by capturing atmospheric carbon through carbon sequestration process. Thus, medicinal plants ensure soil, food, climate, and health security for maintaining ecosystem health and environmental sustainability. Similarly, different medicinal pastures can feed many grazing animals; therefore, feed supply is also counted as ecosystem services. Global productions of medicinal plants deliver multifarious ecosystem services for ensuring health and wealth of peoples and regulate climate [54].

5 Medicinal Plant Utility and Sustainability

Overexploitation and unsustainable use of medicinal plants affects biodiversity, ecosystem health, and ecological stability. It not only deprives health and productivity of medicinal plants but also affects people and animals they are depended on them. Destructive or illicit harvesting, slow growth performance, and restricted distribution are major causes of medicinal plants destruction and species disappearance [55]. Deforestation, intensive farming practices, and other anthropogenic activities affects distribution, diversity, and regeneration of medicinal plants. Therefore, sustainable use of medicinal plants, its conservation, and scientific management are necessary for ecosystem health and ecological stability. Sustainable utility of whole plant parts in formulating herbal drugs delivers greater services and advantages to people. Moreover, different parts of the same plants have similar pharmacological activities but have varying sustainable resources. For examples, extractives of roots and leaf-stem from ginseng (*Panax ginseng*) have equal pharmacological activities but leaf-stem of ginseng is a more sustainable resource [56]. Most of the medicinal plants have great taste and strong odor along with their greater medicinal value. These medicinal plants are also a good source of food and peoples used in daily life for their sustenance of life [57]. Sustainable uses of some important medicinal plants are depicted in Table 1 [58–60].

Sustainable harvesting and usage of medicinal plants are gaining wider recognition, which helps in biological resource conservation. Medicinal resource conservation is an urgent concern, which requires many scientific research, policy supports, and academic assistance for enhancing sustainability. Harvest timing, techniques, equipments, and material to be harvested, etc., are important parameters for conservation, management, and sustainable production of diversified medicinal resources. Moreover, good quality medicinal plants and its sustainable collection must be promoted for efficient utilization of diversified medicinal resources. Anthropogenic pressure for illicit harvesting can also be reduced by sustainable collection and optimum utilization of these medicinal resources. Therefore, case studies on conservation and sustainable use of medicinal plants in the world is depicted in Table 2.

Table 1 Sustainable uses of important medicinal plants [58–60]

Medicinal plant details	Distributions in India	Sustainable medicinal uses
Aonla (*Emblica officinalis*), Euphorbiaceae	Region of Maharashtra, Gujarat, Rajasthan, and Uttar Pradesh	Plants used for curing hemorrhagic disorders, anemia, asthmatic problem, and jaundice
Guggal (*Commiphora wightii*),Burseraceae	Distributed throughout Indian continent	It is a gum producing tree of medicinal value used for curing of rheumatoid arthritis
Senna (*Cassia angustifolia*), Caesalpinaceae	Region of Maharashtra, Rajasthan, Gujarat, Tamil Nadu, and New Delhi	Plant parts such as pod and leaves used for treatment of constipation
Safed musli (*Chlorophytum borivillanum*), Liliaceae	Mostly found in Southern region of the Rajasthan, Madhya Pradesh, and Gujarat	Plant characterized by tuberous root systems, which is highly recommended for Ayurvedic medicines for treatment of various disease
Satavari (*Asparagus racemosus*), Liliaceae	Distributed throughout India	Plant characterized by tuberous root systems, which is highly recommended for treatment of hemophilic disorders, diarrhea, swellings, and blood dysentery
Long pepper (*Piper longum*), Piperaceae	Distributed throughout India	Root is highly medicinal and used for treatment of chronic bronchitis, leukoderma, cough, epilepsy, and asthma
Brahmi (*Bacopa monnieri*), Scrophulariaceae	Distributed throughout India	Plant part such as leaves is used for nervous disorder especially as memory enhancer
Ashoka (*Saraca asoca*), Leguminosae	Distributed in the region of Himalayas and Western Peninsula	Bark system is highly medicinal and used for treatment of uterine affections and internal bleeding
Ashwagandha (*Withania somnifera*), Solanaceae	Mostly found in Rajasthan and Madhya Pradesh	Plant root system is used for treatment of rheumatism and weakness from old age
Indian barbery (*Berberis aristata*), Berberidaceae	Distributed in the region of Himalayas, Bihar, and Assam	Whole plants have medicinal properties, which are used for the treatment of skin disease, diarrhea, and jaundice
Isabgol (*Plantago ovata*), Plantaginaceae	Distributed throughout the plain region of Punjab, Sindh, and rarely found in Baluchistan	Seed husk has high medicinal properties used for treatment of dysentery and constipation
Kokum (*Garcinia indica*), Clusiaceae	Mostly found in Goa, Assam, West Bengal, Maharashtra, and Kerala	Mainly ripe fruits are utilized for preparation of Kokum syrup, which helps in eradication of many diseases

(continued)

Table 1 (continued)

Medicinal plant details	Distributions in India	Sustainable medicinal uses
Kalmegh (*Andrographis paniculata*), Acanthaceae	Distributed over Indian continent	Plant parts such as leaves used for treatment of many chronic diseases including malaria, anemia, jaundice, etc.
Acorus calamus L., *Bacopa monnieri* (L.), *Leonotis leonurus* (L.), *Uncaria rhynchophylla*, *Calotropis gigantea* (L.)	Distributed over most part of Asia, Africa, and Latin America in the world	Plant parts helps in eradication of neurological disease such as epilepsy

6 Selected Phytochemicals of Medicinal Plants

Medicinal plants enhance the health security of people and become a greater alternative for modern medical treatments. Plants are synergistically connected with people's life, death, illness, and aging and maintains socioeconomic and cultural relations. Medicinal plants help in diagnosis of many diseases and its treatments. Plants are greater source of safe medicine due to presence of varying phytochemicals [68]. Phytochemicals characterized by various medicinal properties help ecosystem health and functioning. Antimicrobial, anticancerous, and wound healing properties are key characteristics of phytochemicals. It also promotes metabolic activity, helpful in oral health and neuropathy. Therefore, medicinal properties of phytochemicals are depicted in Fig. 2 [69, 70].

Understanding phytochemicals, its identification, and compositions in medicinal plants is an important baseline for many researchers for treatment of disease and infections [71]. Alkaloids, steroids, tannins, cardiac glycosides, anthraquinones, favonoids, reducing sugars, saponins, and phlobatannins are important phytochemicals in medicinal plants [72]. Phytochemical components induce medicinal power in varying traditional plants that significantly promotes different pharmacological action on the human body [73]. Moreover, phytochemicals components are classified into two major groups, viz., primary and secondary, which are based on varying metabolic action in the plants. Amino acids, proteins, sugars, and chlorophyll constitute the primary group whereas saponins, alkaloids, phenolic compounds, flavonoids, and tannins constitute the secondary group of phytochemicals components [74]. Phytochemicals and its significant antimicrobial effects are depicted in Table 3. Similarly, pathogens can be suppressed by various defense mechanisms due to the production of phytochemicals in the plants. These plants are used to treat many immunological, metabolic, and neurological disorders in the people across the world. Practicing tissue culture helps in production of different phytochemicals and bioactive compounds in medicinal plants. Phytochemicals production can also be enhanced by artificial plant culture techniques of medicinal plants [70].

Table 2 Case studies on conservation and sustainable use of medicinal plants in the world

Medicinal plants (MPs)	Methodology and study features	Results and conclusions	References
A total number of 249 medicinal plants (MPs) selected in the Suriname	Study carried for understanding of unsustainable uses and overharvesting of medicinal plants. It includes monitoring and analysis of survivorship of the selected medicinal plants	Not more than half of the medicinal plant was exploited from wild. Plant part, such as leaves, was harvested extensively. Man-made and secondary forests were used for harvesting of medicinal plants. Losses and decline of medicinal resources were not reported in this study	[61]
Study includes ten of endangered and rare medicinal plants (MPs)	Study carried in the region of Kedarnath Wildlife Sanctuary, Central Himalayas, India for estimating population structure, distribution pattern, and their conservation status by analyzing species diversity, density, and occurrences in selected regions	This study resulted in medicinal plants grouped into two levels as healthy distribution with less pressure and limited distribution with high pressure. It provides insights for sustainable usage with better management and conservation strategies of selected medicinal resources	[62]
Study includes medicinal plants (MPs) such as *Amorphophallus, Camellia sinensis* (tea plant) and *Musella lasiocarpa* (Chinese dwarf banana) in selected regions of the China	Chinese Yunnan Province was selected for the study, which dealt for conservation and management of medicinal plants-based agro-biodiversity conservation and their sustainable uses	Study emphasized both in situ and ex situ conservation of medicinal resources, which helps in maintaining agro-biodiversity conservation and relevant ecosystem services for ensuring environmental sustainability	[63]
Study includes medicinal plant such as *Abies guatemalensis* in the Guatemala region of Central America	Study carried out a nation-wide survey with effective methodology on plantation owners, retailers, and urban consumers between 2004 and 2007	Study observed a declining production cost of plantation with increasing importance of legal supplies by involvement of local peoples in conservation and management of available medicinal resources	[64]

(continued)

Table 2 (continued)

Medicinal plants (MPs)	Methodology and study features	Results and conclusions	References
Study includes medicinal plant such as *Rheum tanguticum* in the region of China	Study conducted for analyzing distribution pattern of *Rheum tanguticum* through TCMGIS-II (a GIS-based program), which integrate climatic situation, geographical areas, and soil types of selected sites of China	Create a roadmap for conservation, scientific management, and sustainable usage of medicinal plant	[65]
Study includes medicinal plant such as *Scutellaria baicalensis* in the region of Northeast to Northwest China	Study carried for analyzing structure and genetic diversity of wild and cultivated population of *Scutellaria baicalensis* by involving polymorphic chloroplast fragments	Study focused on conservation-by-cultivation, which is effective for genetic resource protection and its sustainable uses among local communities	[66]
Study includes 27 threatened medicinal plants from 40 European countries	This study has undertaken 51 number of conservation projects, which surveyed 119 and 25 botanical gardens in 29 and 14 European and other countries	Study showed many medicinal plants were not efficiently collected and were outside of the country jurisdiction. However, collection from botanical gardens were slanted toward different ornamental plant species which were a poor reflection of conservation priority	[67]

7 Threatened Medicinal Plant Resources and Species Rarity

India, which recorded 2.4% of global geographical area, encompasses approximately 8% of world biodiversity [84, 85]. Indo-Burma, Sundaland, Western Ghats, and Himalayas are four main biodiversity hotspots of the Indian territory among the total 35 GBH (global biodiversity hotspots) [86]. Phyto-diversity richness is experienced due to the presence of a total of 15 agro-climatic zones, which have diversified ecological habitats. India accounts for approximately 10.45% of the world's floral. Similarly, 35 GBH (global biodiversity hotspots) hold approximately 50% of the global plant diversity that enveloped 15.9% of global land areas that is now reduced to only 2.30% [87]. However, the existing number of hotspots harbor many endemic species, which have been extinct due to natural and anthropogenic activities [88]. In this context, the first publication of "The IUCN Red List of

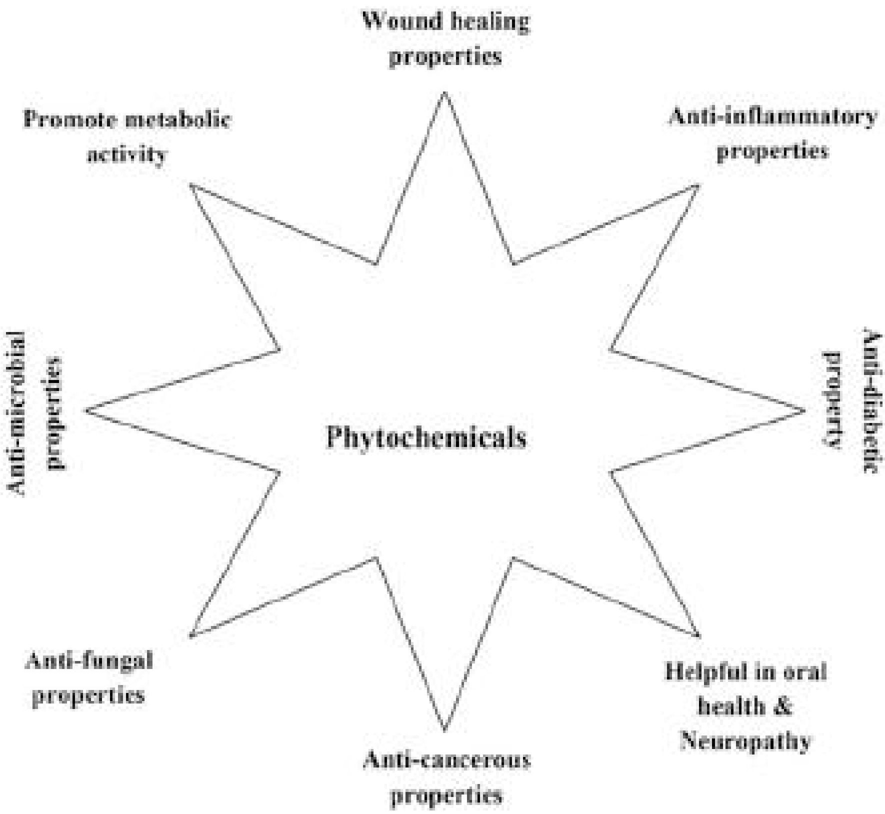

Fig. 2 Medicinal property of phytochemicals [69, 70]

Table 3 Phytochemicals and its significant antimicrobial effects

Source	Observed microbial species	Effects	References
Carrot (*Daucus carota*) seed oil	*Helicobacter pylori*	Antibacterial effects	[75]
Tea (*Camellia sinensis*) oil	Mycoplasmas species		[76]
Essential oils of medicinal plant	*Haemophilus Influenza, Streptococcus pyogenes, Moraxella* catarrhalis, and *Streptococcus pneumoniae*		[77]
Essential oils of medicinal plant	HSV-1 (Herpes simplex virus)	Antiviral effect	[78]
Clove (*Syzygium aromaticum*) and oregano (*Origanum vulgare*) oil	Poliovirus and Adenovirus		[79]
Essential oils of medicinal plant	Coronavirus		[80]
Essential extract of wild stevia (*Stevia rebaudiana*) plant	Fusarium and Aspergillus species	Antifungal effects	[81, 82]
Lycopene chemical	Zearalenone producing species		[83]

Threatened Plants" was reported in the year 1998, which reported 8000 species under threat [89]. Approximately 13.49% of the global vascular plants numbering 40,468 species are reported under varying degrees of threat. A total of 123 and 37 number of plant species are extinct in the wild due to anthropogenic activities, reproduction losses, population and pollinator losses, and habitat destruction [90, 91]. Similarly, approximately 11.53% of vascular plants are red listed under IUCN threatened category [90]. However, 90% of medicinal plants are threatened due to overexploitation and unskilled harvesting techniques [92]. Similarly, 1000 medicinal plant species are reported threatened at varying degrees in different ecosystems of India [93]. However, 602 threatened vascular plants in the Red Data Book has further increased up to 1255 and 2152 in the year 2003 and 2020, respectively [90, 94]. IUCN has categorized medicinal plants into various threatened categories at the world and national levels. IUCN categorized threatened plant species into Extinct (EX), Extinct in the Wild (EW), Critically Endangered (CR), Endangered (EN), Vulnerable (VU), Lower Risk-Conservation Dependent (LR/cd), Near threatened (NT), Least concern (LC), and Data Deficient (DD). Least concern (LC) species recorded maximum as 18,403 (global) and 1545 (national) whereas 7072 and 6063 species are Vulnerable (VU) and Endangered (EN) in the world. Hundred and twenty-three species are Extinct (EX) globally due to overexploitation and its unsustainable usage. Similarly, 2774 (global) and 103 (national) number of plant species are categorized under Data Deficient (DD), respectively. Therefore, plant species threatened at world and national levels as per IUCN estimation is depicted in Fig. 3 [90]. Similarly, IUCN threatened status of medicinal plants in different regions of India is depicted in Table 4 [90, 95, 96].

Rising demand for medicinal plants leads to overharvesting of many medicinal resources from the,wild which later decline existing populations. For examples, indiscriminate extraction of taxol from *Taxus baccata* (Himalayan yew), which helps in ovarian cancer treatment cause decline in population. Similarly, over-exploitation of many other medicinal plants such as *Polygonatum verticillatum, Nardostachys grandiflora, Gloriosa superba, Aconitum heterophyllum, Arnebia benthamii,* and *Megacarpoea polyandra* caused these species to be ranked under rare and endangered categories. Similarly, many medicinal plants are exploited for curing many diseases. For examples, medicinal plants such *Hemidesmus indicus*, *Aegle marmelos*, *Phyllanthus emblica*, and *Gloriosa superba* were used for treatment of 34, 31, 29, and 28 types of diseases [98]. Therefore, overexploitation and indiscriminate uses of medicinal plants not only affects regeneration, distribution, and diversity but also affects livelihood of forest fringe people [18].

8 Medicinal Plant at Risk Under Changing Climate: Implications on Its Phytochemical Constituents

Climate change becomes a major hurdle in the success of SDGs (Sustainable development goals) of the nation [99–101]. Extreme weather due to changing climate has deleterious effects on harvester's and cultivar's potential to cultivate and collect many medicinal resources. This type of experience is observed in

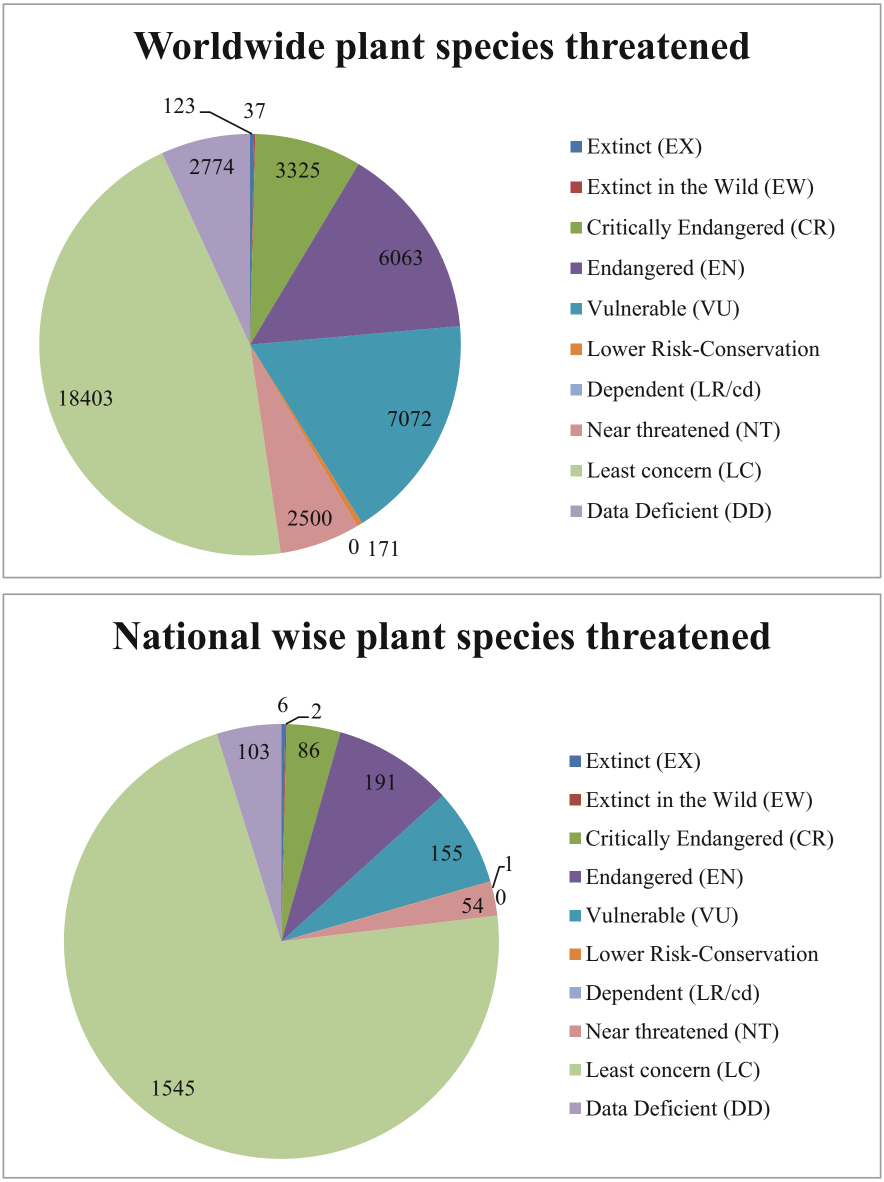

Fig. 3 Plant species threatened at world and national level as per IUCN estimation [90]

Europe, Poland, and Germany and across the entire world [102]. Africa's Sahel region also experienced severe droughts in the twentieth century. Extreme and severe drought badly affected many medicinal plants such as Boswellia spp., *Adansonia digitata* (baobab), *Moringa oleifera* (moringa), *Commiphora africana* (myrrh),

Table 4 IUCN threatened status of medicinal plants in different regions of the world including India [64, 90, 95–97]

IUCN threatened status	Medicinal plants	Regions
Critically endangered (CR)	*Aconitum chasmanthum*	J&K in India
	Aquilaria malaccensis	Tripura, Assam, Arunachal Pradesh, and Meghalaya
	Lilium polyphyllum	J&K, Himachal Pradesh, and Uttarakhand
	Valeriana leschenaultii	Tamil Nadu, Karnataka, and Kerala
Least concern (LC)	*Acorus calamus*	Tripura and Chhattisgarh
	Berberis aristata	West Bengal, Himachal Pradesh, and Sikkim
	Drosera indica	Madhya Pradesh and Karnataka
	Fraxinus floribunda	Sikkim in India
	Gloriosa superba	J&K, West Bengal, Kerala, Uttarakhand, Chhattisgarh, and Maharashtra
	Gmelina arborea	Madhya Pradesh in India
	Juniperus communis	Himachal Pradesh in India
	Toona ciliata	West Bengal in India
	Zeuxine strateumatica	Madhya Pradesh in India
Vulnerable (VU)	*Boswellia ovalifoliolata*	Andhra Pradesh in India
	Diospyros paniculata	Karnataka and Kerala
	Nilgirianthus ciliates	Mostly in Kerala and Tamil Nadu
	Phyllanthus indofischeri	Andhra Pradesh in India
	Santalum album	Mostly in Kerala, Tamil Nadu, and Maharashtra
	Abies guatemalensis Rehder	Mostly in Central America in Mexico, Guatemala, Honduras, and El Salvador
Endangered (EN)	*Cinnamomum wightii*	Mostly in Kerala and Tamil Nadu
	Humboldtia vahliana	Mostly in Kerala and Tamil Nadu
	Cycas circinalis	Orissa, Karnataka, Tamil Nadu, and Kerala
	Piper barberi	Tamil Nadu and Kerala
	Syzygium alternifolium	Andhra Pradesh in India
	Taxus wallichiana	J&K, Himachal Pradesh, Arunachal Pradesh, Meghalaya, and Sikkim
	Diplostephium rhododendroides	Central and South America.

(continued)

Table 4 (continued)

IUCN threatened status	Medicinal plants	Regions
Data deficient (DD)	*Coscinium fenestratum*	Kerala and Karnataka
Near threatened (NT)	*Pterocarpus marsupium*	Orissa, Chhattisgarh, West Bengal, Madhya Pradesh, and Rajasthan
	Pterocarpus santalinus	Tamil Nadu and Andhra Pradesh

Hibiscus sabdariffa (hibiscus), and Aloe spp. Therefore, rising cases of climate change has distressed ecosystem health and harvesting of medicinal plants [103]. *Triticuma estivum* (wheat), *Plantago ovate* (psyllium), *Cuminum cyminum* (cumin), and Indian psyllium crops are damaged by frequent rainstorms and hails due to climate change. Heavy rainfall in monsoon also affects the presence of menthol crystals in *Mentha arvensis* plant of Northern India [104]. Therefore, hailstorms and uncertain rainfall becomes key factors, which severely affects biological, reproductive, and phytochemicals constituents of many medicinal plants. Climate change also affects hurricane seasons, which further influence diversity and production attributes of medicinal plants [105]. Furthermore, elevated CO_2 has influenced the quality and productivity of medicinal plants. Increased value of root numbers and leaf fresh weight in *Mentha piperita* (peppermint) and *Ocimum basilicum* (lemon basil) have been reported due to increased value of CO_2 levels which is reported as 3000 μl CO_2 L^{-1} of air [106]. Similarly, alteration of secondary chemicals productions in many medicinal plants are also due to changing value of ozone (O_3) concentrations in the environment. Elevated O_3 promotes physiological stresses, which further encourage stimulation of different metabolic pathways (for examples, jasmonic acid and salicylic acid pathways) in the plants [107]. Further, elevated temperature may enhance many volatile organic compounds in plants [108].

9 Conservation Strategy

Medicinal plant can be conserved through in situ and ex situ practices. National parks (NPs), biosphere reserves (BRs), joint forest management (JFM), and some mmedicinal plant conservation areas are included under in situ conservation. Many herbal and botanical gardens, seed bank, cryopreservation, gene banks, different tissue culture repositories, etc., are included under ex situ conservation technique. A systematic cultivation of many medicinal plants can be adopted for biodiversity conservation and protection of various threatened species. However, different social, scientific, and political challenges become hurdles behind conservation and management of biodiversity [109]. Assessing the status of threatened plants and accordingly prioritizing the species conservation are prerequisites under multifarious biodiversity and limited resources. In this context, an IUCN (the International

Union for Conservation of Nature)-based “Red List of Threatened Species” has been established, which provides various scientific data on species diversity, distribution, and their extinction risk [110, 111]. IUCN has categorized species into different categories, viz., EX (extinct), EW (extinct in wild), CR (critically endangered), EN (endangered), VU (vulnerable), NT (near threatened), LC (least concern), and DD (data deficient) as per their threatened nature. These categories are based on quantitative criteria, which is a good indicator of different extinction risk [112]. Approximately, 16.5 m ha (5.02%) and 70.8 m ha (21.54%) of the total geographical area is shared by protected areas and forests in India. Similarly, National parks (NPs), wildlife sanctuaries (WS), community reserves, and conservation reserves (CRs) accounted 104, 551, 127, and 88 of the total 870 numbers of protected areas (PAs). Similarly, sacred groves (SGs) ranges from 100,000 to 150,000 in India [113]. However, many organizations have initiated research on conservation and management of medicinal plants. Institutes such as CCRS (Central Council for Research in Siddha), CCRUM (Central Council for Research in Unani Medicine), CCRAS (Central Council for Research in Ayurvedic Sciences), CCRH (Central Council for Research in Homoeopathy), ICFRE (Indian Council of Forestry Research and Education), and CIMAP (Central Institute of Medicinal and Aromatic Plants) have undertaken several researches on medicinal resource conservation. Several institutes of ICAR (Indian Council of Agricultural Research) have also strengthened policy and roadmap for adopting better scientific strategies of medicinal resource conservation. Moreover, many international organization, ayurvedic practitioners, and industries have successfully participated in cultivation and scientific conservation of these medicinal resources across the world [114]. National Gene Banks for Medicinal and Aromatic Plants has also coordinated with four institutes such as CIMAP, RRL as Regional Research Laboratory, ICAR-based NBPGR (National Bureau of Plant Genetic Research), and Jawaharlal Nehru Tropical Botanic Garden and Research Institute (JNTBGRI). This coordination has emphasized on better collection, propagation, and sustainable uses of medicinal plants [9]. Similarly, 1200 taxa herbals were collected in 10 acres of land from and Jawaharlal Nehru Tropical Botanic Garden and Research Institute (JNTBGRI). A total of 3334 and 2476 accession in seed and field gene bank are being maintained at CIMAP [115]. Cryo-gene bank, seed bank, in vitro, and field gene bank are key facilities provided by ICAR-NBPGR for scientific management and conservation of medicinal plants across the country. A total 8071, 1041, and 178 accession in seed gene bank, cryo-gene bank, and in vitro gene bank is being maintained at ICAR-based NBPGR [116, 117].

NMPB has been constituted under the Ministry of AYUSH, which was established by Government of India (GoI) in the year 2000. It provides funds for research and development for medicinal plants. DST (Department of Science and Technology) and DBT also promote many researchers to focus on medicinal plant-based research. *Aconitum ferox*, *Crocus sativus, Commiphora wightii*, *Cassia angustifolia*, *Saraca asoca, Bacopa monnieri*, *Phyllanthus amarus*, *Ocimum sanctum*, *Withania somnifera*, *Tinospora cordifolia, Piper longum, Emblica officinalis, Santalum album*, *Garcinia indica, Aegle marmelos, Swertia chirata*, *Plantago ovate*, *Solanum nigrum*, *Piper longum,* and *Andrographis paniculata* were important medicinal plants that needed conservation priority by NMPB in 2019 [118]. Similarly, 72 MPCDAs (Medicinal Plants Conservation and Development Areas) have been created for in situ conservation of medicinal plants in 13 states which covered 10,935 ha in forest areas [119]. Moreover, 108 MPCAs (Medicinal Plant Conservation Areas) and 18 MPCPs (Medicinal Plants Conservation Parks) have been established under partnership with State Forest Departments (SFDs) and DANIDA (Danish International Development Aid) to give financial supports to them [120]. These conservation strategies have emphasized on medicinal plant conservation and its sustainable uses across the country. DBT has also started a program for conservation of threatened and extinct plants with the help of biotechnological tools and by which approximately 100 medicinal plant species are conserved [121]. A total of 115 species were reintroduced under this project whereas 106 and 76 species were standardized through macro- and micropropagation protocols [121]. Therefore, "Reintroduction" is great strategy or scientific approach for re-establishment of threatened plants into suitable areas. *Syzygium travancorium*, *Calophyllum apetalum*, *Vanda coerulea*, *Ceropegia fantastica*, *Decalepis arayalpathra*, *Mahonia leschenaultii*, *Blepharistemma serratum, Berberis napaulensis*, and *Heracleum candolleanum* are key threatened medicinal plants conserved through successful application of reintroduction [122–125]. A total 156 medicinal plant species reported as highly threatened have been conserved through species-specific recovery programs adopted by DBT in the recent years [126].

10 Constraint and Challenges

A scientific research on medicinal plants gained significant attention from national and international platform. Medicinal plants also received wide recognition due to uncountable ES (ecosystem services), which includes biodiversity conservation, poverty alleviation, climate change mitigation, and health security. However, a deep fragmentation remains occur in data related to institutional arrangements, utilization methods, and medicinal plants production system. This creates hurdles in the development of an inclusive research agenda related to medicinal plant conservation and management in Asia [127]. Rising global population and their dependency on plant resources resulted in pressure on natural forests. This led to overexploitation and unsustainable usage of medicinal plants, which becomes a greater challenge for environmentalist. Overexploitation and unsustainable usage of medicinal resources reduce regeneration, species distribution, productivity, and ecosystem health. This is a key constraint and global challenge faced across the world. Increasing global population cause resource exploitation for meeting daily requirements of food and medicines, which increases the dependency on natural forests. This incident obviously increases erosion of forests and its related products [128]. Thus, it necessitates global challenges for conserving useful medicinal resources. A lack of correct information of demand, supply, and profits of various medicinal resources are other constraints. Lack of good market structure affects revenue generation from many medicinal plant resources, which becomes challenging from marketing and economic perspective. A poor knowledge on traditional medicinal system also affects people's health care system. Unsustainable harvesting of these medicinal plants is further excavated by poor scientific knowledge within the community stakeholders. Similarly, poor scientific knowledge on plant propagation, lack of proper resources, and negligence of fund flow are common constraints that affects production and market economy of medicinal plants. Adopting intensive farming practices utilize excessive agrochemicals and pesticides which affects valuable medicinal plants by affecting health and productivity. Peoples get affected negatively by consuming theses pesticides-based medicinal plants. Agrochemicals-induced medicinal plant productions also affects soil health and productivity, which becomes a global challenge for soil scientists. Higher use of agrochemicals enhances agricultural productivity but affects humans, plants, and environmental health negatively. Higher synthetic inputs not only degrade soil quality but also affect humans and animals due to disturbance in the food web and ecosystems [129, 130]. Further, agrochemical usage in agriculture poisons the food system that affects human, animal, and environmental health. Excessive usage of pesticides and its dependence is detrimental to human and the whole health and sustainability of the ecosystem [131].

Adopting sustainable or ecologically oriented cultivation practices of medicinal plants can overcome all these constraints. Moreover, practicing innovative agriculture ensures sustainable food system and creates resilience in the farming system the world over [132–135]. Thus, an eco-friendly scientific approach is needed for removal of harmful agrochemicals or pesticides residuals that can ensure healthy plants, human, animal, and whole the ecosystem, which is framed in "One Health" concept for sustainable environment. A good agriculture practice with efficient harvesting techniques also enhances medicinal plant productivity. Efficient processing unit, adequate infrastructure, and value addition of various medicinal plant products can ensure sustainability and production of medicinal resources. Poor infrastructure, lack of technological support and expertise, and low economic support also resulted in challenging situations for the global markets. Further, global competition among various pharmaceutical industries leads to overexploitation of medicinal plants. This unsustainable practice leads to scarcity of medicinal resources, which directly or indirectly affects ecosystem productivity and the global health care system. Thus, a perfect examination of such complex issues is required for cultivation, conservation, and sustainable usage of medicinal plants, which will further open the door for global market in the medical industry.

11 Strategic Plan and Policy Framework

Exploiting medicinal resources and its unsustainable uses under limited natural resources caused decline in medicinal plants and poor health care system. Climate change also affects the availability of medicinal plants by depriving its productivity, quality, and health system. Similarly, intensive farming practices utilized excessive agrochemicals and pesticides, which also affect valuable medicinal plants by affecting health and productivity [136–138]. These natural and anthropogenic practices push medicinal plants into threatened at higher risk which needs constructive strategic plan and policy reformation for better conservation and management of medicinal plants. The Government of India (GoI) has developed policy and some regulatory frameworks for medicinal plants conservation and its sustainable uses from both wild and cultivated areas. Indian Forest Act (1927), The Forest Conservation Act (1980), Wildlife Protection Act (1972), National Biodiversity Strategy and Action Plan (NBSAP, 2002), Biological Diversity Rules (BDRs, 2004), Forest Dwellers Act (FRA, 2006), National Wildlife Action Plan (NWAP, 2017–31), Export Import Policy (EIP, 2015–20), etc., have developed effective policy and some regulatory frameworks for medicinal plants conservation and its sustainable uses across the world. Similarly, National Medicinal Plant Board (NMPB) has also initiated many constructive policies, strategic plans, and scientific programs for low cost cultivation practices, proper collection, harvesting, processing, and sustainable uses of raw and value-added products of medicinal plants. Policy governance and institutional support are also needed in scientific research and development in different marketing sectors of medicinal plants. CITES agency has initiated an agreement with government for prohibiting illegal trade of many medicinal plants, which leads to species being threatened. A total of 28,000 and 5000 number of plant and animal species, respectively, have been protected by CITES through adopting better strategic action plan and constructive policy [139].

12 Scientific Research and Future Recommendation

Medicinal plants gained wider recognition due to varying herbal products but these are disappearing at an alarming rate. Scientific research and future recommendation are necessitated for defending medicinal losses as threatened and species rarity in the safeguards of humans. Diversion and shifting of traditional medicine practices to modern medicine system are interesting part of the research today [50, 140]. A degraded land can also be utilized by planting many medicinal and aromatic plants, which helps in eco-restoration and environmental management along with climate change mitigation [141]. Understanding phytochemicals, its identification, and compositions in medicinal plants are important baselines for many researchers for treatment of disease and infections [71]. However, many organizations have initiated research on the conservation of medicinal plants. Scientific research on medicinal plants has gained significant attention from national and international platforms. Policy governance and institutional support are also needed for scientific research and development in different marketing sectors of medicinal plants. A scientific research is needed on mega-network project for both in situ and ex situ conservation of medicinal plants. Similarly, a challenge has been rising due to high cost of botanical garden and gene bank establishment, which may also lead to plant losses under extreme climate, disease infestation, and frequent natural disasters. Therefore, cryopreservation, seed conservation, and in vitro conservation-based practices are prioritized for effective research to claim long-term safe conservation of medicinal plants. Moreover, research and development are required for collection of indigenous and quality plant material for strengthening its higher productivity and sustainable uses. Similarly, a future roadmap should be created for conservation of medicinal plants with relevant information on national gene/seed bank, which can ensure availability of diversified medicinal plants for current and future generation [142].

13 Conclusion

Traditional medicinal practices have been popularized in the world since time immemorial. Medicinal plants cure many diseases and ailments due to the presence of important phytochemicals, which provides better lifestyle for humans. Medicinal plant diversity and its importance gained wider recognition globally due to higher medicinal usage. Diversified medicinal resources have greater medicinal significance, which cures many diseases and ailments in the world. However, overexploitation and unsustainable uses of medicinal plants affects biodiversity, ecosystem health, and ecological stability. It not only deprives health and productivity of medicinal plants but also affects people and animals as they are dependent on them. Climate change also affects availability of medicinal plants by depriving its productivity, quality, and health system. Similarly, intensive farming practices utilize excessive agrochemicals and pesticides, which affect valuable medicinal plants by affecting health and productivity. In this context, maintaining medicinal plant diversity ensures a variety of ecosystem services, which maintains ecological stability and environmental services. Soil enrichment, water regulation, health security by disease management, greater plant productivity, and climate change mitigation are key ecosystem services provided by medicinal plants. Thus, global productions of medicinal plants deliver multifarious ecosystem services for ensuring health and wealth of people and regulate climate. Moreover, good quality medicinal plants and their sustainable collection must be promoted for efficient utilization of diversified medicinal resources. Therefore, herbal medicines promise good health of the ecosystem and provides health security for greater sustainability. Constructive policies and plans are needed for conserving and sustainable usage of important medicinal plants that have herbal and ethanobotanical importance. Moreover, a scientific research and future recommendation are necessitated for defending medicinal losses as threatened and species rarity in the safeguards of humans.

Abstract

Man uses plants as a source of fuel, food, medicine, shelter, fodder, and other forestry products. Vegetables are any component of a plant that may be eaten whole or in part, raw or cooked and include leaves, stems, roots, flowers, seeds, fruits, bulbs, tubers, and fungus. Nigeria is endowed with an abundance of vegetables that are used both as food and for therapeutic reasons. Huge amounts of vegetables are grown in Nigeria, and astounding numbers are sometimes cited as the projected yearly output. Vegetables are particularly essential for nutrition and health, especially since they include chemicals that control or promote digestion, function as laxatives or diuretics, and contain pectins and phenoic components that help control the intestines' pH levels. Both urban and rural residents' incomes are boosted by vegetables. Native American tribes' documentation of wild food plants helps in planning, identifying dangers, developing conservation strategies, and determining nutrient and pharmacological contents. As a result, this chapter covers an overview of edible vegetables in Nigeria, risks to common edible plants with pharmaceutical potential in Nigeria, and conservation efforts for those common edible vegetables.

1 Introduction

Plants of every colour and kind have been used as sustenance for both people and animals from the beginning of time. Numerous crops have historically served as sources of food, medicine, and nourishment. Today, both humans and animals regularly consume about 10,000 indigenous food species throughout the globe. Again, during the last five centuries, there has been a rise in population contact as well as worldwide trade, and as a result, around 20% of these crop species are now utilized internationally and form the foundation of most of the world's agricultural production. However, many of the plant species that are grown for food across the globe are either underused, neglected, or both. According to studies, consuming the micronutrients and some phytochemicals found in these plants contributes to better health and lower rates of illness especially the ones associated with microorganisms [1–24]. Furthermore, they can be used in the control of insects such as mosquitoes [25–29]. Indigenous plants provide advantages for human health, in addition to enhancing local communities' access to food. There is widespread food insecurity in Nigeria due to hunger, malnutrition, and a lack of certain micronutrients in the diet, which is the main source of energy and sustenance [30].

Vegetables are any component of a plant that may be eaten whole or in part, raw or cooked, and they can include leaves, stems, roots, flowers, seeds, fruits, bulbs, tubers, and fungus [31]. However, similar vegetables are referred to as leafy vegetables when the component consumed as a vegetable is mostly from the leaves. They may also be referred to as potherbs, salad greens, vegetable greens, or leafy greens. Although they originate from a very diverse range of plants, some of them share a lot in terms of nutrients and preparation techniques with other green vegetables [32]. Due to their contributions to the nutrition security of millions of people, indigenous vegetables are becoming more and more popular [33]. The most affordable and widely accessible sources of vitamins, proteins, minerals, antioxidants, carbs, and amino acids are found in them. They keep the body's alkalinity balanced by serving as buffers for the acidic byproducts of digestion. Constipation is avoided by the fibre content, which supplies the bulk needed for digestion. In all parts of Nigeria, traditional medicine also uses vegetables as a kind of treatment. Their bioactive phytochemical components, which cause distinct physiological changes or activity in the body, are what give them their therapeutic potential. In certain situations, these bioactive phytochemicals have served as helpful building blocks for the creation of medicinal agents and practical pharmaceuticals [34].

The intake of diverse vegetables by a sizable portion of the world's rural population, according to Singh and Arora [35], helps them satisfy a portion of their nutritional needs. Vegetables have been shown to be very important to the food culture of people in Nigeria and all of Africa [36]. Many African households often consume a lot of green vegetables. In total, 115 of the 150 food plants that men regularly eat are native to Africa [37]. Furthermore, eating leafy greens has been linked to a number of health benefits, including the ability to stave against certain age-related degenerative disorders including arteriosclerosis and stroke [38]. According to Kimiywe et al. [39], several green vegetables have been linked to the treatment of various ailments. They give low resource people an alternative form of income in addition to acting as supplemental food and medicine [40]. Malnutrition and hunger have been noted by Obel-Lawson [41] to be threats to millions of people in sub-Saharan Africa, according to Jansen van Rensburg et al. [42].

However, it has been shown that eating green vegetables benefits both rural and urban people' nutrition, health, and economic well-being. Nigeria is renowned around the globe for its rich botanical diversity, which may be utilized in a variety of ways for culinary, medical, therapeutic, and nutritional reasons [43]. Leafy vegetables are a part of this enormous plant variety. Green leafy vegetables have been widely accepted as nutritional components in various regions of Nigeria, where they often make up a significant section of the diet when used to make soups and stews. It is regrettable that several of the traditional green vegetables that have long been utilized as food and medicine are now being gradually neglected. Traditional green vegetables have often been underused due to neglect. Civilization and a lack of knowledge about the nutritional and therapeutic advantages to many populations are factors that contribute to such underutilization [44]. Other concerns include industrialization; lack of suitable propagation practices to promote yield, quality, and quantity; regional conflicts that cause significant rural to urban migration; and the displacement of people [45]. As a result, this chapter covers an overview of edible vegetables in Nigeria, risks to common edible plants with pharmaceutical potential in Nigeria, and conservation efforts for those common edible vegetables.

2 Overview of Edible Vegetables in Nigeria

In sub-Saharan Africa, vegetables are often referred to as green or soft edible fruits that may be eaten fresh as a salad or cooked in a stew [46]. Some of these edible parts may be leafy, such as bitter leaves, water leaves, fluted pumpkins, mint leaves, lemon grass, and *Amaranthus hybridus*. African green vegetables aid in supplying the daily needs for nutrients. Sub-Saharan African rural residents were recognized as having a mandatory requirement to boost their intake of vegetables [47]. As they include both macro- and micronutrients, including dietary fibre; different vitamins like A, C, and K; as well as minerals like iron, potassium, and zinc to support human health development, vegetables play a significant part in the diet and nutrition of humans [48, 49].

Leaf vegetables are inexpensive, easy to prepare, and packed with nutrients, including vitamin C and B-carotene, which are critical for human health. Vegetable intake has been closely linked to stress reduction and a lower risk of developing chronic illnesses [49]. It is crucial to enhance this information since, for example, potassium-rich foods may lower blood pressure [50–52]. According to Gido et al. [53], different families eat a broad variety of green vegetables in varied ways. It may be argued that leafy greens alone have the ability to preserve maximum health. However, by enhancing the diet and diversifying the food options that are easily accessible in the field, traditional vegetables have the potential to help reduce malnutrition among the people in rural regions [54]. According to the RDA, these native vegetables in Nigeria have not been consumed to their full potential in Nigeria [55, 56]. The following list of frequently used edible vegetables is discussed:

2.1 Water Leaf (*Talinum triangulare*)

Talinum triangulare, a short-lived perennial succulent shrub that is susceptible to cold weather, is a member of the Portulacaceae family. The term "bologi" is used locally in Nigeria and is pronounced "gbologi" in the Ukwani dialect of Delta State. Without cultivation, it may grow naturally on its own. The flavour, suppleness, and taste of *Talinum triangulare* are well recognized. It is an excellent source of several crucial minerals including magnesium and potassium as well as antioxidant vitamins [57]. It is also high in fibre, protein, and other vitamins needed for a healthy human diet [58]. According to research by Ikewuchi et al. [57], waterleaf has significant amounts of antioxidant, antibacterial, and anti-inflammatory effects. Managing the metabolic syndrome, which includes diabetes, high cholesterol, and hypertension, is also a possibility [59–62]. Due to its high potassium content (Ikewuchi et al., [57], waterleaf soup is used in Nigeria as a treatment for hypertension [58].

2.2 Fluted Pumpkin (*Telfairia occidentalis*)

Fluted pumpkin is also known as ikongubong (Efik/Ibibio), eweroko (Yoruba), ugu (Igbo), and offi (Ukwani) in Nigeria. *T. occidentalis* is mostly grown in West Africa; it is also known by other regional names in other regions of Africa, including pondokoko or Gonugbe (Sierra Leone) and krobonko (Ghana). This vegetable crop is a perennial in the Cucurbitaceae family that is grown extensively for its tasty and nutrient-rich leaves. It is often planted as an outdoor home food plant. *T. occidentalis* is not an exception to the fact that vegetables are recognized for both their antioxidant and phenolic chemical characteristics [63, 64]. As compared to other regularly consumed green vegetables, fluted pumpkin leaves are exceptionally rich in minerals including calcium, phosphorus, and iron [65]. Although it may not be a trustworthy source of protein, the moderate amount of fibre and high nutritious value support its many uses [66]. The consumption of fluted pumpkin may be able to shield people from the negative effects of oxidative stress on their health [65]. Based on mineral contents, it is hypothesized that pumpkin leaf's very high potassium concentration may help to reduce hypertension [51, 52]. Additionally, foods with high iron contents may be utilized to treat anaemia and may help to increase blood production. Additionally, the presence of zinc increases the antioxidant capacity of the food [67], which may help, for instance, with the control of diabetes [60, 68].

2.3 Bitter Leaf (*Vernonia amygdalina*)

Nearly everywhere in the world grows bitter leaf plants for home consumption, particularly in the tropical parts of Africa like Nigeria. It is a natural-regenerating shrub or small tree [69]. They thrive in environments that are fully humid and sunny. It typically grows in the wild or is farmed near lakes, rivers, wooded areas, and open grasslands [70]. Etidot (Efik/Ibibio), onugbu (Igbo and Ukwani), and Ewuro (Yoruba) are some of the native names used in Nigeria. In Nigeria, the renowned bitter-leaf soup contains spices made from *V. amygdalina* leaves [71]. Extracts include a variety of phenolic and phytochemical components. According to a recent study, the nutritional qualities are equivalent to those of mint leaf [72], which is what follows in the text. In comparison to all other vegetables, it has reportedly been shown to be extremely high in folic acids and vitamin C [47]. Traditional herbal therapy employs *V. amygdalina*. According to Uusiku et al. [47], one of this vegetable's many traditional applications is to treat malnutrition, which may be brought on by a lack of certain micronutrients. It is also said to decrease cholesterol [73], cure infections [71], and be helpful in the treatment of diabetes [74, 68].

2.4 Mint Leaf (*Ocimum gratissimum*)

Local names for the smell leaf, also known as mint leaf (*Ocimum gratissimum*), in Nigeria include efinrin nla (Yoruba), alulu-nta (Ukwani), and dadoya (Hausa). It is grown in residential vegetable gardens and has the ability to recover as well as grow wildly. The high antioxidant content of mint leaves helps to flavour food, reduce salt consumption, and give taste to dishes. Mint and bitter leaf are equivalent in terms of the close makeup of their nutritional contents [75]. It is a spice that is often used in African cuisines as well as in tea. Because of the menthol and mint essential oil in mint leaves, aromatherapy has long been connected with them [76]. Asthma, a cough, and a cold have all been treated with it [77]. It is used to treat diabetes [78] and has been suggested as a possible anticancer [79].

2.5 Green Amaranth (*Amaranthus hybridus*)

Local names for *Amaranthus hybridus*, also known as green tete or morogo, include tete (Yoruba), alaiyaho (Hausa), inine (Igbo), and shorokotom yokotor (Ukwani). It may be farmed but also grows naturally in the farms. Amaranthus is very nutrient-dense; both the leaves and the grain amaranth are used as food for both humans and animals. The amaranth was found to be the healthiest in terms of fat content while being equivalent to bitter leaf, mint leaf, and waterleaf in terms of fibres in a research that examined the proximate composition of 10 plants in Southern Nigeria [80]. Due to its iron and antioxidant characteristics, *A. hybridus* has a significant potential to ameliorate micronutrient deficiency [81]. This green vegetable grows organically in the Ndokwa communities' fields in Delta State, Nigeria, making it a free source of food rich in micronutrients. It is important to highlight that zinc affects fertility and that it may help control diabetes [82].

2.6 *Moringa oleifera*

The *Moringa oleifera* plant, often known as the miracle tree, horseradish, or drumstick tree, is grown for both medicinal and culinary uses [83]. In Igbo and Ukwani, respectively, it is known as okwe or okwe-oyibo in Nigeria. It thrives as a tree in both rural and populated areas, although in the latter it is all but gone. *M. oleifera* is recognized as a highly beneficial dietary source to maintain excellent health as well as a conventional treatment for a variety of illnesses, according to Vergara-Jimenez et al. [84]. The leaves of the plant may be used raw, cooked, or powdered while retaining their nutritional value. *Moringa oleifera* leaves provide more vitamin C than lemon and orange, according to Mbailao et al. [85]. Vergara-Jimenez et al. [84] found that these leaves contain a large number of bioactive compounds, including antioxidants. A variety of disorders, such as high cholesterol, hypertension, liver problems, stress, infection, and diabetes, have been studied in relation to the use of moringa oleifera leaf as an alternative therapeutic agent [83, 86–88]. It's noteworthy to note that it has just recently begun to be used to treat a variety of medical conditions [89].

2.7 Lemon Grass (*Cymbopogon citratus*)

In the family Poaceae, commonly referred to as non-native plants, lemon grass is a native species. It is used to prepare chicken dishes and is known as atta-okuku and atta-oyibo in the Ukwani community in Delta State, Nigeria. It grows naturally but is also farmed in other nations, for example, as a cash crop. Lemon grass has equivalent nutritional contents as chives and pumpkin leaves. Particularly, it is said that lemon grass contains around 14 times as much manganese as chives [50]. In fact, as herbal infusion, lemon grass is utilized in tea [90, 50]. In traditional medicine, lemon grass has been used for a very long time to cure a variety of ailments, including diabetes and high cholesterol [91, 92]. Recently, the therapeutic value of lemongrass was evaluated [93].

2.8 *Piper guineense*

Nigeria and other countries in West Africa place a high value on the vegetable species *Piper guineense*, also known as West African black pepper or Ashanti pepper. Its aromatic flavour and medicinal properties have made it a popular spice and condiment in traditional cuisine. Ogunwande et al. [94] found that *P. guineense* extracts had antimicrobial and anti-inflammatory properties. Adedire et al. [95] found that it had promising results as a natural insecticide and larvicide.

2.9 *Gongronema latifolium*

Gongronema latifolium, or Utazi as it is known in Nigeria, is a leafy green vegetable that has both culinary and medicinal applications. *G. latifolium* leaves are frequently used as a seasoning in classic dishes like soups and stews. Because of their antioxidant and anti-inflammatory properties, they may be useful in the treatment of diseases brought on by oxidative stress. Animal research has also shown that *G. latifolium* extracts have antidiabetic effects [96].

2.10 *Murraya koenigii*

Curry leaf, or *Murraya koenigii*, is a common ingredient in Indian cooking thanks to its pungent aroma and flavour. *M. koenigii* has important medicinal properties in addition to its culinary uses. Alkaloids, flavonoids, and phenols are just some of the bioactive compounds found in abundance in the leaves; these compounds have antioxidant, antimicrobial, and anti-inflammatory properties [96]. Because of these characteristics, *M. koenigii* shows promise as a treatment for a wide range of conditions, including diabetes, inflammation, and gastrointestinal issues.

2.11 *Colocasia esculenta*

Starchy root vegetable *Colocasia esculenta*, also called taro or cocoyam, is commonly grown in tropical areas. Many people rely on it as a main source of nutrition because of the high amount of carbohydrates it contains. *C. esculenta* is also well-known for its therapeutic benefits [97]. Its antimicrobial and anti-inflammatory properties have shown promise in wound healing research [98]. It has been found that *C. esculenta* leaves have diuretic and antihypertensive properties, so they are used in traditional medicine as well [99].

2.12 *Amaranthus hybridus*

Slender amaranth, or *Amaranthus hybridus*, is a leafy vegetable that is popular in many parts of the world. Vitamins, minerals, and anti-oxidants abound in it, making it an excellent source of nourishment. Several health advantages have been linked to *Amaranthus hybridus* consumption. Due to its high bioactive compound content [100], it has been shown to have the potential to lower blood pressure and improve cardiovascular health. *Amaranthus hybridus* has also shown promise in warding off chronic diseases thanks to its extracts' anti-inflammatory and anticancer properties [101].

2.13 *Solanum macrocarpon*

The African aubergine, or *Solanum macrocarpon*, as it is more commonly known, is a staple of traditional African cuisine. Because of its high nutrient content and possible health benefits, it is widely consumed. *Solanum macrocarpon* fruits have anti-inflammatory and free radical-scavenging properties because they are high in antioxidants, especially phenolic compounds. *Solanum macrocarpon* is an important component of traditional medicine due to its antimicrobial and antidiabetic properties [102].

2.14 *Pterocarpus mildbraedii*

Pterocarpus mildbraedii, or African padauk, is a tree species with multiple traditional medical applications. Bioactive compounds with anti-inflammatory, antimicrobial, and antioxidant properties have been found in *Pterocarpus mildbraedii* bark, leaves, and roots [103]. These characteristics suggest that it may be useful in the search for natural therapeutic agents to combat inflammatory and infectious diseases. Wound healing properties have also been observed in experimental studies using *Pterocarpus mildbraedii* extracts [104].

2.15 *Basella alba*

Basella alba is a leafy green that is popular in many Asian and African cuisines. It is also known as Malabar spinach and vine spinach. It's a great source of nutrients like B vitamins, minerals, and fibre. The antioxidant and anti-inflammatory properties of *Basella alba* have been studied and reported to have promising medical applications. Traditional medicine has long made use of *Basella alba* for its beneficial effects, particularly on digestion and the treatment of gastrointestinal disorders [105].

2.16 *Heinsia crinita*

Vegetables native to Central and West Africa include the species *Heinsia crinita*, also known as false sesame or Ntonga. *Heinsia crinita* seeds are loaded with healthy nutrients like protein, fat, and minerals [106, 107]. They have traditional medicinal and culinary uses. Antioxidant and anti-inflammatory properties may be present in the seeds [108]. The antimicrobial properties shown by *Heinsia crinita* extracts also make them a candidate for use as a natural preservative.

2.17 *Trigonella foenum-graecum*

Fenugreek, or *Trigonella foenum-graecum*, is a herbaceous plant that has both culinary and medicinal applications [109]. Bioactive compounds like flavonoids and saponins abound in *Trigonella foenum-graecum* seed. Historically, they have been used to aid digestion and reduce inflammation and blood sugar levels [110]. Trigonella foenum-graecum extracts have been studied and reported to have potential cholesterol-lowering effects [111]. In addition, studies on the effects of fenugreek seeds on breastfeeding mothers have been encouraging [112].

2.18 *Taraxacum officinale*

The herbaceous plant known as dandelion, or *Taraxacum officinale*, can be found in many different regions around the world. It has long been used for its medicinal properties. The antioxidant, anti-inflammatory, and hepatoprotective properties of *Taraxacum officinale* can be attributed to the plant's high concentration of bioactive compounds, such as sesquiterpene lactones, phenolic acids, and flavonoids [113]. In addition, diuretic and antimicrobial activities have been observed in tests of *Taraxacum officinale* extracts [114]. Because of these qualities, it has long been used in alternative medicine to treat conditions like liver disease, UTIs, and gastrointestinal distress.

2.19 *Jatropha tanjorensis* Ellis

The plant species *Jatropha tanjorensis* Ellis, also known as bellyache bush, is native to various parts of Africa. For centuries, its healing properties have led to its use in alternative medicine. Anti-inflammatory and analgesic bioactive compounds have been found in *Jatropha tanjorensis* Ellis [115] in both the leaves and the roots. In addition, Ukuuiwe et al. [116] found that *Jatropha tanjorensis* Ellis extracts may have antifungal and antimicrobial activities. Based on these characteristics, it may be useful in relieving pain, reducing inflammation, and fighting off infections.

2.20 *Crassocephalum rubens*

Crassocephalum rubens, also known as red flower rag leaf, is a popular leafy vegetable across many countries in Africa. It's useful as both food and medicine. Vitamins, minerals, and phytochemicals like flavonoids and phenolic compounds can all be found in *Crassocephalum rubens* leaves. They are able to combat free radicals and reduce inflammation [117]. Donga and Chanda [118] found that *Crassocephalum rubens* extracts had a hepatoprotective effect and an anti-diabetic effect in animal studies. These results point to its possible use in the treatment of metabolic disorders and the avoidance of chronic diseases.

2.21 *Solanum americanum*

American nightshade, or *Solanum americanum*, is a plant species found all over the world. It is also known as glossy nightshade. It has been utilized for its therapeutic qualities in conventional medicine. Bioactive compounds with antioxidant, anti-inflammatory, and anticancer activities have been found in *Solanum americanum* leaves and fruits [119]. Kumar et al. [120] review the research on its antimicrobial and wound-healing properties. *Solanum americanum* extracts have also been used traditionally for the management of diabetes, and research has shown that they have antidiabetic effects [121].

2.22 *Celosia argentea*

Cockscomb, also called silver cock's comb, is the common name for the ornamental and edible plant species *Celosia argentea*. It has long been valued for both its edible and medicinal qualities. The antioxidant and anti-inflammatory properties of *Celosia argentea* can be attributed to the presence of bioactive compounds like flavonoids and phenolic acids in the plant's leaves and flowers. Antimicrobial activity against a wide range of pathogens has been suggested for the plant extracts [122]. *Celosia argentea* has also been used to treat gastrointestinal disorders, skin conditions, and cardiovascular diseases in traditional medicine.

2.23 *Solanum nigrum*

Black nightshade, or *Solanum nigrum*, is a wildly distributed plant species that can be eaten and used medicinally. Bioactive compounds with antioxidant, anti-inflammatory, and antimicrobial properties have been found in *Solanum nigrum*'s leaves, fruits, and roots [123]. In addition to its traditional uses for treating diabetes, skin disorders, and gastrointestinal issues, *Solanum nigrum* extracts have shown promising anticancer effects [124]. It should be noted, however, that some *Solanum nigrum* varieties are toxic, so use caution if you plan to eat them.

Some other vegetable species with ethno-medicinal properties are indicated in Table 1 below.

3 Threats of Common Edible Vegetables That Possess Pharmacological Potentials in Nigeria

The accessibility of common edible vegetables in Nigeria that have the capacity to be used in medicine is being put in jeopardy by a variety of variables which encompass everything from the effects of global warming to the effects of social and economic variables. All of these variables have been contributing to a restricted access of these plants as well as their costly nature, both of which may result in major consequences

Table 1 Common edible vegetables that possess pharmacological potentials in Nigeria

S/N	Scientific name	Family	Type of vegetable	References
1	*Talinum triangulare*	Portulacaceae	Leafy	[125]

for the general well-being of the general public. In the following subsection, discussions on the challenges that posed threats to the accessibility of common edible vegetables in Nigeria that have the capacity to be used in pharmaceutical uses are made (Fig. 1).

3.1 Global Warming

The availability of widely consumed vegetables in Nigeria has been significantly impacted by global warming. Diminished harvest rates due to temporal shifts, altered precipitation sequences, and severe weather patterns have impacted both the quantity and quality of these plants [136].

Changing patterns of precipitation have been identified to be among global warming's greatest influences the accessibility of common edible vegetables in Nigeria. Desertification and floods, caused by shifts in the frequency and intensity of precipitation, are capable of having a catastrophic impact on harvests. The elevated temperatures along with inadequate precipitation, for instance, have been illustrated to reduce the output of bitter leaf, a popular vegetable in Nigeria [137]. Shifts in precipitation and temperature additionally influence the harvest of African aubergine, a different widely consumed vegetable [138]. These shifts have the potential to lessen supply and raise the prices of these veggies.

The temperature climbs due to global warming also have an effect on the production of crops, alongside shifts in precipitation patterns. Diminished development, delayed blossoming, and fewer harvests are all possible outcomes associated

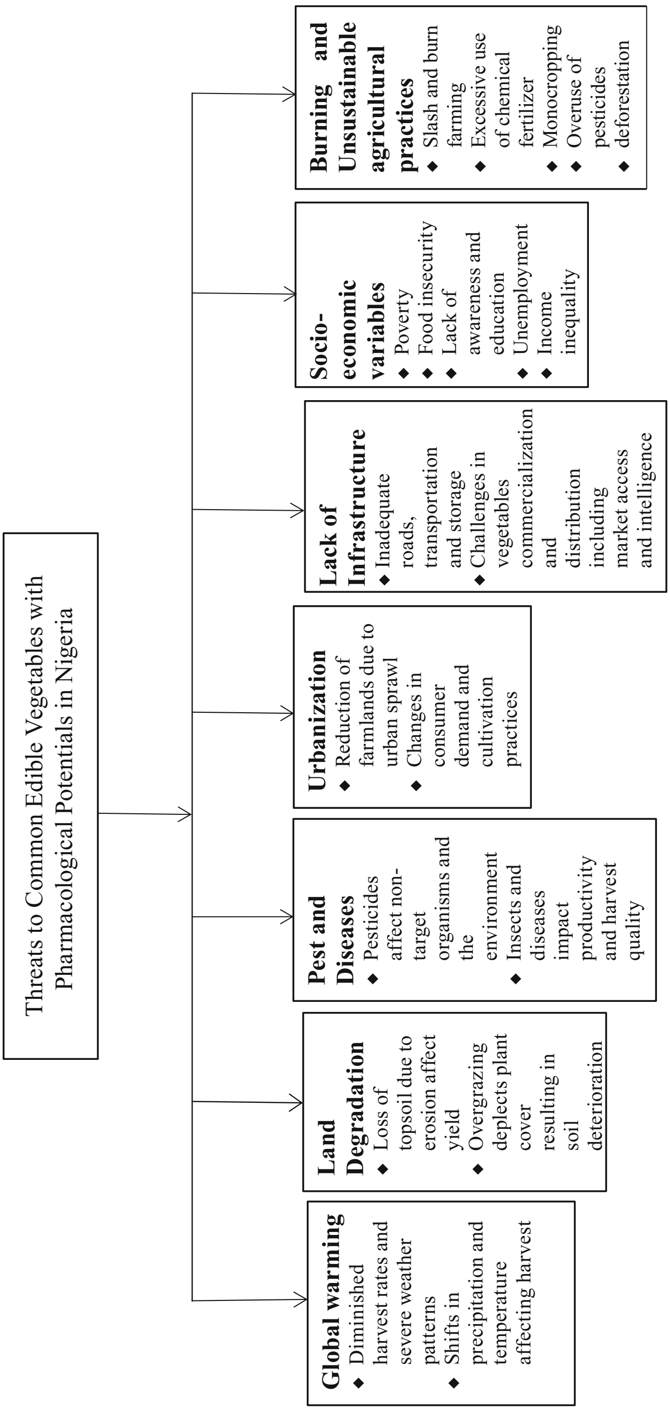

Fig. 1 Threats of Common Edible Vegetables of Pharmacological Potentias in Nigeria

with temperature fatigue, which can be brought on by rising temperatures. Okra, amaranth, and jute mallow are all widely consumed veggies in Nigeria, but research shows that rising temperatures may diminish the yields they produce [139].

Inundations and windstorms are just two examples of catastrophic weather conditions that can significantly reduce harvests [140]. Agricultural products can be harmed by inundation, resulting in a decreased yield, and by violent gales, that has the potential to spoil or otherwise harm agricultural produce. For instance, Babatunde et al. [141] reported that widespread inundation in Nigeria in 2012 wrecked farming operations, which led to shortfalls of pumpkins, waterleaf, and leafy greens.

The soil's state is also impacted by global warming. Destitution of the soil as a consequence of fluctuating temperatures, altered precipitation patterns, or additional grave climate-related circumstances possess the potential to cause a detrimental effect on the production of crops. As an example, a decrease in okra output has proved to be associated to the deterioration of the soil in recent years. Additional grave climate-related circumstances possess the potential to cause a detrimental effect on the production of crops [144]. As an example, a decrease in okra output has proved association to the deterioration of the soil in recent years. Okra is a popular Nigerian vegetable [143], driving up the price of already-expensive vegetables.

3.2 Land Degradation

Deterioration of land is a major ecological challenge that has an immense effect on the accessibility of staple foods like veggies in Nigeria [142]. The clearing of forests, overgrazing, and bad farming techniques are all examples of the degradation of the environment that humans have caused [143–149, 25]. The accessibility and value of commonly consumed veggies in Nigeria may be negatively impacted by these actions due to eroding soil, poor soil fertility, and decreased productivity of crops [150].

When the topsoil is lost due to erosion of the soil, soil that is less productive that is capable of supporting good crop development is left behind. Some of the frequently consumed veggies in the country have had their yields decreased due to the loss of soil [143] which causes the loss of vital nutrients for plants like nitrogen and phosphorus.

The accessible nature of staple fruits and vegetables in Nigeria can be negatively affected by overgrazing. When an excessive number of livestock nibble an area, excessive grazing causes plant life to be depleted and the ground's condition to deteriorate [146]. The depletion of plant cover due to excessive grazing is a risk factor for soil deterioration and decreased fertility. Fruits and vegetables like leafy greens and pumpkins are affected because they need a lot of cover from plants and soil that is fertile [141].

The application of synthetic pesticides and fertilizers are two examples of unsuitable farming techniques that have contributed to land deterioration and reduce the supply of staple vegetables in Nigeria. The acidification of the soil and the accumulation of salt caused by too much application of inorganic fertilizers may diminish fertility in the soil and impact the development of crops [136]. Soil quality and quantity of agricultural produce are likewise adversely influenced by the elimination of insects that are beneficial and microbes caused by the application of pesticides.

3.3 Pest and Diseases

Due to the rise in pests, the use of pesticides including weedicides, insecticides, fungicides, acaricides, etc. are on the rise. Many of these pesticides have the ability to affect non-target organisms and cause an alteration in the environmental matrices [151–162]. Significant financial consequences diminished availability of food and raised cost of food may culminate from the negative effects of pests and diseases on the productivity of crops [163]. Insects and disorders have a significant effect on agricultural production in Nigeria, thereby affecting the accessibility of common vegetables.

The decline in agricultural productivity is a major problem caused by pests and diseases. Tomatoes, the okra plant, and peppers are especially vulnerable to harm from pests like the aphid, mites, and thrips in Nigeria [164]. Insect pests like the aforementioned feed on plants by extracting the juices out of the stems, foliage, and fresh fruit. This kind of feeding behaviour can cause the plant to develop growth defects, lose its vegetative cover, and produce lesser quantity fruits. Vegetable plants are susceptible to harm from a variety of diseases, including bacterial wilt, powdery mould, and blight [165], and can as well affect the quantity and quality of harvests.

The cost of groceries for customers may rise if pests and diseases force agriculturalists to spend more money on the production process. In order to forestall and control pests and diseases, agriculturalists can find themselves spending money on chemicals such as pesticides and fungicides and other prevention techniques. Farmers on small farms might have no accessibility to cost-effective pesticides, making these steps prohibitive. When deployed incorrectly or in excessive amounts, pesticides along with other forms of control measures can be harmful to the well-being of humans and the environment [166].

Pests and diseases also pose a threat to the integrity of our food supply. *Salmonella* and *E. coli* can also pose a threat to the quality and health of fruits and vegetables. Therefore, pest and disease control is fundamental to guaranteeing the freshness, quality, and hygiene of food for shoppers.

3.4 Urbanization

The accessible nature of commonly consumed vegetables in Nigeria has been significantly impacted by urbanization [167]. Vegetable consumer demand has shifted as cities expand, resulting in modifications to the cultivation and distribution process.

The reduction of farmland due to urbanization is a major factor in reducing access to fresh produce. There is less agricultural land readily accessible for farming because of urban sprawl converting farmland into housing and business districts [168].

As a result of this shortage of farmland, vegetable production has fallen in certain regions. For instance, accelerated urbanization has reduced land for farming and lowered vegetable production in the city of Lagos, the nation's most significant urban area [169], thereby reducing the accessibility of fruits and vegetables.

The changing consumer needs for particular vegetable forms is yet a further consequence of urbanization on vegetable being accessible. Exotic and highly valuable vegetables like lettuce, cucumbers, and broccoli are in greater popular demand as urban areas expand. Variations in the cultivation and distribution of vegetables have resulted from the changes in appetite, with producers and marketers making adjustments to satisfy the increasing need for exceptionally valuable vegetables at the expense of more common varieties [170].

Vegetable commercialization and distribution have also been impacted by urbanization [167]. As cities expand, the travel distance between agricultural operations and marketplaces grows, increasing the difficulty of transporting vegetables and fruits in the absence of suitable logistics and storage infrastructure. As a result, deterioration and transit damage have increased losses following harvest. Furthermore, rural farmers have faced growing rivalry as a result of the increased shipment of vegetables to meet the frequent use in urban areas [169].

3.5 Lack of Infrastructure

Common edible vegetables in Nigeria are significantly harder to come by due to the absence of facilities. Transmission and sales of vegetables have been hampered by the country's inadequate facilities, which include roads, conveyance, and warehouses, leading to a shortage of these foods. Significant losses following the harvest are one way in which poor infrastructure reduces the accessibility of vegetables. Because of poor infrastructure, a large portion of Nigeria's vegetable produce is lost after being harvested. The majority of farmers do not have the ability to access adequate facilities for storage, which results in wasted food and crops that never make it to the marketplace. The damage is compounded because vegetables and fruits cannot easily be transported from remote regions to urban centres because of the poor condition of highways and transportation infrastructure [171].

Moreover, because of these challenges, farmers are losing money on their crops and fewer vegetables are available on the marketplace as a whole. Vegetable storage has become problematic due to a scarcity of cold storage spaces, forcing farmers to offload their harvest as soon as possible at a loss [172].

Additionally, the low output of Nigerian vegetable farms can be attributed to the country's inadequate infrastructure. Low yields are a result of the fact that most vegetable farms lack accessibility to essential commodities like water and fertilizer. Vegetable farming in the country hinges on precipitation, which makes it challenging for producing fruits and vegetables throughout the entire year due to a shortage of infrastructure for irrigation. Because of this, vegetable accessibility in the marketplace is now seasonal in nature resulting in higher prices outside of peak growing months [96].

3.6 Socioeconomic Variables

Common edible vegetables in Nigeria are significantly affected by socioeconomic factors. Vegetable availability and demand are affected by socioeconomic variables such as financial status, schooling, and accessibility to marketplaces [163, 173].

The financial standing of household members is a socioeconomic variable that has a substantial effect on the accessibility of vegetables [145]. Because of price, economically disadvantaged Nigerian families have restricted accessibility to many food items, as well as vegetables. Nutritional deficiencies along with additional health issues arise because people in such families eat a narrow diet that is constantly nutrient-wise inadequate. However, because they are able to spend to buy more produce, households with higher incomes have a wider selection of foods available to them [174].

Vegetable accessibility in Nigeria is also affected by schooling level of a family. Vegetables are an essential part of a diet that is nutritious, but they aren't always seen as such. Those with a higher level of education are a greater probability to understand the importance of eating vegetables on a regular schedule. Farmers are encouraged by the rising interest for vegetables to produce greater quantities of these foods for sale [175].

In addition, the accessibility of marketplaces is a crucial socioeconomic component influencing the accessibility of vegetables in Nigeria. Agriculturalists who have convenient accessing in the marketplaces are capable to market their goods to a larger customer base, driving up both requests and sales of vegetables. However, vegetable cultivation and accessibility fall when producers are incapacitated to maximize earnings from marketing their goods [176] due to a lack of marketplace access [177].

The absence of a proper distribution system in farming communities where the majority of vegetables originate is also a factor. Vegetables being available in urban centres, in which they are in tremendous demand, tends to decrease because of the difficulty of transporting them there due to bad road network and coveyance facilities. The farmers' inability to market their crops usually caused charges to drop and output to decrease for farmers growing vegetables in remote locations [178].

3.7 Bush Burning and Unsustainable Agricultural Practices

The intentional burning of plant material in undeveloped land, known as "bush burning," is a common agricultural practice in Nigeria for a number of motives, such as clearing land for cultivation, controlling insects, as well as encouraging regeneration [163, 166]. As a result of the depletion of natural environments, fragile ecosystems are disrupted [179, 180], which has devastating effects on Nigerian vegetables. Vegetable populations are dwindling as a direct result of habitat loss, which is also responsible for the extinction of some plant species [181, 182]. Destroying this cover through bushfires increases the risk of deterioration and decreases soil fertility [181]. This has a chilling effect on the development and output of Nigerian vegetables [168]. Vegetables in Nigeria come in a wide variety of species, and many of them have special health benefits. Thus, the loss of biodiversity is exacerbated by the practice of bush burning as it kills off plants and reduces genetic diversity. Also, vegetables' ability to withstand and adapt to environmental changes is diminished as a result of this loss [183, 184].

The threats to Nigerian vegetables are also exacerbated by ineffective agricultural practices, such as the wasteful use of agrochemicals, poor land management, and excessive exploitation [184]. Excessive tillage, poor soil nutrient administration, and forest loss are all examples of poor land management practices that contribute to soil degradation. Consequently, vegetable growth and yield are negatively impacted because of the soil's diminished organic matter, fertility, and structure [185, 186]. Water depletion and pollution are also exacerbated by unsustainable irrigation practices like wasteful use and inadequate management [187]. As such, vegetable production is hindered by the lack of water, while polluted water supplies endanger both vegetable crops and human health. Furthermore, pest management practices that encourage the excessive and careless use of synthetic pesticides have negative outcomes for people and the planet. Thus, vegetable growth and nutrient content are negatively affected by the pesticide contamination of soil, water, and air [188].

4 Conservation Strategies of Common Edible Vegetables That Possess Pharmacological Potentials in Nigeria

It is essential to preserve common edible vegetables that have the potential to be used in pharmaceutical applications in order to guarantee their continued use in Nigeria. The preservation of these vegetables' genetic diversity, the prevention of their extinction, and the guarantee that generations to come will have access to them are the primary goals of conservation efforts. In this segment, we will talk about a few of the conservation strategies that can be used in Nigeria to protect common edible vegetables that also have pharmacological potential as indicated in the chart below (Fig. 2).

4.1 Seed Banks

The preservation of common edible vegetables in Nigeria relies heavily on the use of seed banks as an important tool. In accordance with Kehinde et al. [189], seed storage facilities contribute to the preservation of the unique genetic makeup found in plant species, which in turn helps to guarantee the continued existence of different kinds of plants. This is crucial as it facilitates plants to become accustomed to evolving conditions in their surroundings as well as create novel characteristics that include durability against illnesses and pests. The diversity of genes additionally provides opportunities for crops to adjust to shifting circumstances in the

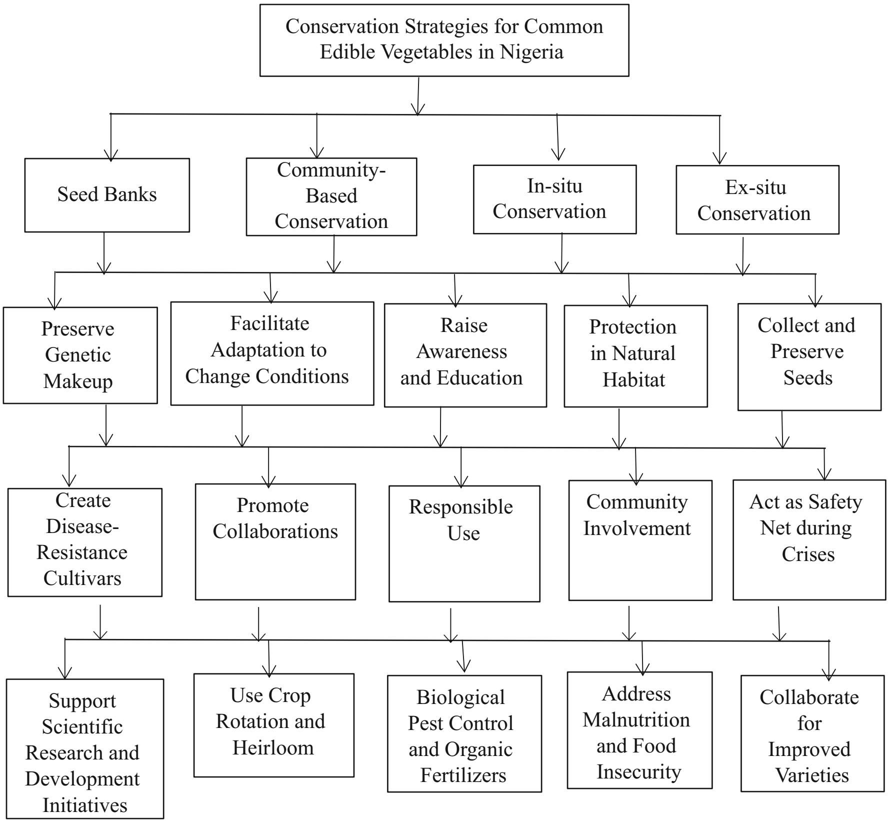

Fig. 2 Conservation strategies for common edible vegetables in Nigeria Conservation strategies of common edible vegetables that possess pharmacological potentials in Nigeria. (Note: The organizational chart provides a hierarchical representation of the conservation strategies, with the main categories branching out into their respective subcategories.)

environment. A seed bank for many different kinds of plants, as well as common edible vegetables, was set up in Nigeria in 2004 by the National Centre for Genetic Resources and Biotechnology (NACGRAB). This bank is known as the National Gene Bank.

Scientists, cultivators, and agriculturalists are all helped greatly from seed banks because they offer a dependable source of gene materials from plants to draw from. This constitutes the single most significant benefit of seed banks. For instance, scientists are able to investigate the genetic makeup of plants, ecological function, and biological processes of various kinds of plants by using seeds that have been stored in seed banks. Geneticists are able to employ seeds to come up with novel cultivars of common edible vegetables that can be immune to pests and diseases, have increased productivity, and are additionally healthy nutrients. These new variations can be produced using seeds. Thus, agriculturalists are able to use seeds to cultivate agricultural products that have improved outputs and are well-suited to the unique circumstances of their particular region.

In order to stop the extinction of vegetative species, seed banks are also an extremely important component. According to Kehinde et al. [189], many plant species including common edible vegetables in Nigeria are on the verge of extinction due to the depletion of their natural habitat, the effects of global warming, as well as additional events carried out by humans. Seed banks play an important role in the conservation of those kinds of plants by preserving the seeds of these plants and making sure that future generations of people will have access to them. For instance, if a kind of plant becomes vanished in its native environment, the seeds of that plant will be reintroduced into its natural environment so that it can continue to exist.

In addition to this, seed banks encourage international collaboration for the purpose of preserving the world's variety of vegetation. According to Doku et al. [190], seed banks are able to swap seeds of many different kinds of plants with one another, which makes it easier for nations to share their expertise and assets. The National Gene Bank at NACGRAB in Nigeria has worked with other internationally recognized organizations, including the International Plant Genetic Resources Institute (IPGRI), to pass on and safeguard the genetic materials of plants. This collaboration has taken place in recent years. This contributes to ensuring that the unique genetic makeup of commonly consumed vegetables is preserved across the world.

4.2 Community-Based Conservation

Okali et al. [191] conducted research into the use of Community-Based Conservation (CBC) in Nigeria to safeguard and oversee a wide variety of flora species, including those that are commonly used in cooking. Because of their often-valuable understanding as well as practices that were handed down across several generations, communities in the rural areas must be involved in initiatives to conserve flora and fauna resources [192–197].

Accordingly, the UNEP [198] argued that CBC serves as a venue for raising awareness and educating people about the value of preserving commonly consumed vegetables. Common edible vegetables, their dietary advantages, and the dangers they encounter are all topics that are discussed and taught in grassroots programmes. By teaching people why and how these vegetables need to be preserved, communities can learn to feel more invested in the conservation effort.

Additionally, Pretty et al. [199] in their study pointed out that CBC encourages the responsible use of commonly consumed vegetables. In many cases, these vegetables are primarily consumed by the local population. CBC guarantees that individual and environmental needs are met through the long-term utilization of these vegetables by engaging them in conservation efforts.

Lastly, CBC aids in generating income and reducing impoverished circumstances in local economies, as stated by the UNEP [198]. The possibilities for seeds and fruit collection and sale can result from efforts to preserve commonly consumed vegetables. Sustainable agricultural practices that raise harvest rates and boost food security can also be fostered by CBC [200]. CBC improves the quality of life for people in rural areas by engaging them in the preservation of widely consumed forest resources [201, 202].

4.3 In Situ Conservation

The term "in situ conservation" refers to the practice of protecting wildlife and their habitats without removing them from their original settings. The conservation of widely available vegetables in Nigeria benefits greatly from this method.

In situ conservation has proved useful in protecting many different kinds of flora species in Nigeria, including some that are commonly eaten, as stated by Onuminya et al. [203]. The authors emphasized that this method includes the conservation and administration of wild plant communities. This method ensures that common edible vegetables will continue to be available for future generations of people by protecting their native environment and genetic variation.

Common edible vegetables are managed and conserved with the help of community members in in situ conservation. Omokanye et al. [204] reported that some local communities in the country have participated in in situ conservation of commonly consumed vegetables. The authors pointed out that these local communities are able to conserve these plants in their communities by keeping these fruits and vegetables in their native environments by employing indigenous expertise and practices.

In situ conservation also encourages the long-term utilization of commonly consumed vegetables. Protecting the areas where these vegetables naturally grow helps to ensure that they will always be around for human consumption. To ensure food security in Nigeria, especially in local communities where these vegetables are a vital source of nutrition, Akpabio and Udo [205] found that the long-term utilization of common edible vegetables is crucial.

In addition, in situ conservation helps to keep cultural artefacts and biological diversity around for future generations [206]. The common edible vegetables studied by Adedayo et al. [207] were found to have major societal and customary worth in Nigeria, in addition to their nutritional benefits. The environment in which they occur and the genetic variation of these vegetables are better protected through in situ conservation efforts.

4.4 Ex Situ Conservation

In addition to in situ conservation, common edible vegetables in Nigeria are also protected through ex situ conservation. Adewale and Ojo [208] describe this strategy as collecting and preserving seeds, plant tissues, and other materials in seed storage facilities, plant museums, and other ecological preservation centres other than of their native environment.

The preservation of commonly consumed vegetables in Nigeria is greatly influenced by ex situ conservation. For starters, it's a safety net in times of crisis, like when extreme weather, maladies, or global warming strike. Avoiding the extinction of key floral species that contribute to our nutritional and food security is made possible through ex situ conservation [209].

Also, ex situ conservation can help revive deteriorating ecosystems. Restoring degraded ecosystems can boost crop yields of staple food crops and increase the variety of plants. Degenerated regions can be revitalized by planting indigenous plant species that thrive in the area's climate and soil conditions with the aid of ex situ conservation [210].

Moreso, germplasm from ex situ conservation efforts can be used in development initiatives. Improved crop varieties with increased yields, resistance to disease and insect pests, and adaptability to shifting climates can't be developed without access to a wide range of genetic resources. Plant breeding programmes can access useful germplasm from ex situ conservation centres, leading to the creation of novel cultivars of crops with enhanced properties [211].

Furthermore, scientific inquiry can benefit from ex situ conservation. Research, including the creation of novel pharmaceuticals, biofuels, as well as other materials, can benefit from the safeguarding of plant remains in ex situ conservation centres. It is possible to learn more about the biology, environment, and genetic variation of commonly eaten vegetables by studying them in ex situ conservation centres [212].

The National Centre for Genetic Resources and Biotechnology (NACGRAB), the Forestry Research Institute of Nigeria (FRIN), and the International Institute of Tropical Agriculture (IITA) are just some of the organizations working on ex situ conservation projects in Nigeria. Common edible vegetables and other plant species are being preserved by these organizations for the benefit of future generations of people [212].

4.5 Promotion of Traditional Farming Practices

Studies have shown that agroforestry systems increase biological diversity and boost the fertility of the soil. In addition to providing cover for crops, preventing the erosion of soil, and encouraging the integration of locally adopted species of naturally occurring plants, planting trees and shrubs alongside crops has many other benefits. Rotations of crops are useful in reviving the fertility of the soil and decreasing diseases transmitted by soil. In addition to aiding in the preservation of the genetic material of plants, this system encourages the use of heirloom cultivars for farming. Biological pest control and fertilizers made from organic materials have been shown to improve agricultural sustainability and mitigate the harmful effects of chemical compounds used as fertilizers on plant life [212, 213].

One group that encourages farmers to stick to tried-and-true methods is the Nigerian Conservation Foundation (NCF). The organization claims that as an outcome of their efforts, rural communities have adopted environmentally friendly agriculture practices like integrating agriculture and forestry, and crop rotation, which have boosted the yields of crops and helped preserve biodiversity.

Consequently, since traditional farming methods encourage environmentally friendly farming and aid in ensuring the preservation of genetic material from plants, they may possess an enormous effect on the preservation of commonly consumed vegetables in Nigeria.

4.6 Plant Breeding and Selection

The preservation of widely consumed vegetables in Nigeria can be greatly aided by plant breeding and selection. These methods focus on creating and selecting novel varieties for agriculture that are efficient, resilient to pests and diseases, and adaptable to a range of environmental conditions.

By encouraging the cultivation of a wide range of cultivars of crops that are suited to the regional climate, plant breeding and selection can aid in the preservation of genetic material from plants. Common edible vegetable yields can be increased and the adverse consequences of global warming mitigated with the assistance of these varieties of crops. Nwalieji et al. [213], for instance, observed that plant breeding to create new cowpea versions increased both the quantity and the quality of the crop in the country.

Plant breeding and selection can also aid in combating malnutrition and extreme food insecurity by creating more nutrient-dense cultivars of crops. Examples of biofortified crops that may assist with addressing deficiencies in micronutrients in at-risk populations include vitamin A cassava, iron pearl millet, and zinc maize [214].

Many organizations and campaigns in Nigeria are working to preserve staple vegetables through breeding and selection programmes. Improved varieties of cassava, yam, cowpea, maize, and soybean have all been created by the International Institute of Tropical Agriculture (IITA), one such organization. Farmers in Nigeria have embraced these varieties of crops in large numbers, which is good news for the future of Nigeria's plant genetic assets as well as food supply.

5 Conclusion

Indigenous vegetables are vital to the Nigerian people's nutritional, physical, and financial well-being. Vitamins, minerals, antioxidants, and other essential nutrients abound in them, making them an important factor in maintaining good health and reducing the incidence of disease. These vegetables are not only an essential source of earnings for many communities, but they also have traditional medicinal uses.

However, there are a number of challenges to preserving and ensuring access to commonly consumed vegetables in Nigeria. The affordability and accessibility of these plants are threatened by factors like climate change, socioeconomic parameters, industrialization, and insufficient propagation practices. Heightened malnutrition and hunger are just two of the ways in which this situation threatens the health of the population as a whole. These problems necessitate the implementation of conservation strategies. The continued existence and variation in genes of common edible vegetables rely on seed banks. They provide a pool of genetic material from which new and better cultivars can be bred and developed. International cooperation and the exchange of genetic resources are two additional benefits brought about by seed banks. In both in situ and community-based conservation strategies, locals are encouraged to take part in the protection and long-term maintenance of staple foods like vegetables. These methods improve the standard of living in rural areas by increasing knowledge, encouraging responsible use, creating economic opportunities, and fostering social cohesion. These methods aid in preserving the native environment and the genetic diversity of these vegetables by engaging local communities in conservation efforts.

In a nutshell, protecting Nigeria's staple food crops is important for a number of reasons, including maintaining food security, improving people's diets and overall health, and maintaining the country's rich cultural heritage. Important steps towards protecting these precious resources for future generations include establishing seed banks, engaging in community-based conservation, and engaging in in situ conservation.

Abstract

Supply chain management (SCM) is a strategic approach that orchestrates the movement of goods, products, and services from their origin to where they are utilized or consumed as a linchpin of organizational success, customer satisfaction, and overall business performance. In the herbal medicine industry (HMI) sector, SCM refers to the process of managing the whole range of value chain activities connected to the sourcing, processing, distribution, and use of plants for medicinal purposes. Sustainable supply chain management (SSCM) is the concept of striving to harmonize economic performance with environmental stewardship and sociocultural equity. The chapter proposed a sustainable supply chain system for the HMI that includes: (1) sustainable cultivation and harvesting of herbal resources, (2) sustainable manufacturing of herbal medicine products, (3) the green distribution process for herbal medicine products, (4) eco-friendly wholesalers, retailers, and vendors of herbal medicine products, (5) sustainable herbal medicine utilization, and (6) herbal medicine waste recovery. There is also a need for a supply chain monitoring system for HMI to ensure quality control and improve relationships and experience among and between the different HMI value chain players. In addition to environmental stewardship, social responsibility, economic viability, regulatory compliance, risk management, and innovation and learning. By integrating the principles of SSCM into the HMI, this chapter contributes to the ongoing discourse on sustainability in healthcare and provides insights for practitioners and policymakers within the industry. It is hoped that the chapter will stimulate further research in this area and inform the development of strategies and policies that promote the sustainable growth of the HMI.

1 Introduction

In the contemporary era of globalization, the intricacies of business operations have escalated exponentially, necessitating the evolution of robust and efficient supply chain management (SCM) systems. SCM is a strategic approach that orchestrates the movement of goods and products from their origin to where they are utilized or consumed. This concept, first introduced by Hugos [1], has become a linchpin of organizational success, influencing cost efficiency, customer satisfaction, and overall business performance. However, as the business landscape has evolved, so too have the expectations and responsibilities of organizations. The traditional focus on economic efficiency and profitability has been supplanted by a more comprehensive perspective that incorporates environmental and social sustainability. This paradigm shift is manifested in the burgeoning interest in sustainable supply chain management (SSCM), a concept that strives to harmonize economic performance with environmental stewardship and social equity. This approach, as outlined by Seuring and Müller [2], represents a significant departure from traditional SCM practices, reflecting a broader societal shift toward sustainability and corporate social responsibility.

The advent of digital technologies and data analytics has further transformed the landscape of supply chain management. Recent literature has underscored the increasing role of these tools in shaping SSCM practices. Studies such as those by Ada et al. [3], and Utami, Anna, and Hidayati (2022) highlight the potential of tools such as big data analytics, Industry 4.0 technologies, and value chain analysis in driving SSCM practices. These technologies offer unprecedented opportunities for organizations to monitor and manage their supply chains in real time, enabling them to respond more effectively to changes in demand, supply, and market conditions. They also provide a means for organizations to track and reduce their environmental impact, contributing to the broader goals of sustainable development.

The herbal medicine industry (HMI) is a significant yet growing sector within the broader healthcare industry and is not immune to these trends. Herbal, botanical, or phytomedicine refers to the use of plants (either wholly or in their parts) for medicinal purposes. This practice has been a cornerstone of healthcare for centuries across various cultures and is now gaining recognition in the modern healthcare system due to its natural origins, perceived safety, and potential health benefits [4, 5, 6, 7, 8]. The World Health Organization [9] has highlighted the importance of herbal medicine in global health, noting its role in primary healthcare and its potential to contribute to the achievement of the United Nations Sustainable Development Goals and targets. However, the HMI faces unique challenges in terms of supply chain management. Given the nature of its raw materials, the complexity of production processes, and the stringent regulatory requirements, managing supply chains in the HMI requires a nuanced and sophisticated approach. The global nature of these supply chains, which often involve sourcing ingredients from diverse locations and exporting products worldwide, adds further complexity to this task. Moreover, the industry must contend with the challenges of sustainability, plant systematics, and urbanization and include the need to conserve biodiversity, reduce environmental impact, and ensure the fair and equitable distribution of resources [10–28].

This chapter aims to evaluate SSCM in the HMI by exploring the application and value of the concepts to the herbal medicine value chain to highlight the key aspects, players, and subdivisions. The chapter also examines the development of the HMI by discussing the status, trends, issues, and potential and actual benefits of SSCM. It will also critically analyze the supply chain systems within the HMI by evaluating how SCM systems can be incorporated into herbal medicine resource sourcing, production, processing, sale, use, and waste management as well as identify potential and actual supply chain issues within the HMI and how these issues may impact the system. The chapter will contribute to ascertaining the benefits of sustainable supply chain development and management practices within the herbal medicine sector and concludes by recommending sustainable supply chain systems and management practices that can enhance the efficiency and sustainability of the HMI. The chapter is organized into six main sections. The first section provides a theoretical background on SCM and SSCM, followed by an overview of the HMI in the second section. The third section delves into the specifics of the supply chain in the HMI, while the fourth section discusses the challenges and issues faced by the industry. The fifth section presents the benefits of SSCM in the herbal medicine sector, and the final section offers recommendations for improving supply chain sustainability in the industry. The chapter concludes with a summary of the main findings and implications for future research and practice. Also, by integrating the principles of SSCM into the HMI, this chapter contributes to the ongoing discourse on sustainability in healthcare and provides insights for practitioners and policymakers in the industry. It is hoped that this chapter will stimulate further research in this area and inform the development of strategies and policies that promote the sustainable growth of the HMI.

2 Concept of Supply Chain Management

Supply Chain Management (SCM) is a complex network of interconnected businesses, each playing a crucial role in delivering products and services to the end customer. This chapter explores the roles and networks of key players in SCM, drawing insights from various scholarly articles. The essence of SCM, as described by Hossain et al. [29], is brought about by the optimal management of the interconnectedness of activities involved in the provision of products and services to meet the needs of the end customers and business owners. This network includes various key players, each with a specific role, contributing to the overall performance of the supply chain.

One of the key players in SCM is the supplier, whose role is to provide raw materials for the production process. The study by Hossain et al. [29] emphasizes the importance of strategic supplier partnerships in improving supply chain performance. These partnerships are crucial in ensuring a steady supply of high-quality raw materials, thereby enhancing the efficiency of the production process. Manufacturers, another key player in SCM, are responsible for transforming raw materials into finished goods. The efficiency of the manufacturing process significantly influences the overall performance of the supply chain. The study by Hossain et al. [29] further highlights the importance of effective management of the manufacturing process in improving supply chain performance. Distributors and retailers are also key players in SCM. Distributors ensure that goods reach retailers, who then sell these goods to the end customers. The study by Kumar and Ostor [30] highlights the importance of effective distribution and retailing strategies in ensuring that goods reach the end customer in a timely and efficient manner. The study by Huang et al. [31] adds another layer of complexity to SCM by exploring the influence of horizontal collaborations on vertical collaborations. The authors argue that these collaborations can significantly influence the dynamics of supply chain networks, thereby affecting the overall performance of the supply chain. The concept of supply chain finance introduces financial institutions as another key player in SCM. These institutions provide comprehensive financial services to enterprises in the supply chain, thereby enhancing the financial stability and efficiency of the supply chain. Therefore, SCM involves a complex network of key players, each with a specific role and responsibilities. The effective management of these roles and the relationships between these players is crucial in enhancing the overall performance of the supply chain. Future research should focus on exploring strategies for enhancing the efficiency of these roles and relationships, thereby improving supply chain performance.

3 Key Supply Chain Responsibilities and Roles

3.1 Suppliers in the Supply Chain: The Starting Point and Beyond

Suppliers, the initial entities in the supply chain, are responsible for providing the raw materials or components that are transformed into finished goods by manufacturers. Their role is critical, as their performance directly impacts the efficiency and effectiveness of downstream operations. The primary responsibility of suppliers is to ensure the availability and quality of the raw materials or components they provide. They must manage their operations to meet the demands of their customers in terms of volume, delivery schedules, and quality specifications. This requires effective production planning, quality control, and logistics management [32]. In addition to providing raw materials or vital production components, suppliers often play a role in product innovation. They also contribute to the development of new products and the improvement of existing ones by providing innovative materials or components, or by collaborating with their customers in the design and development process [32]. Suppliers are also critical in the management of supply chain risks. They can cause disruptions in the supply chain due to factors such as production failures, quality issues, or delivery delays. Therefore, they need to implement effective risk management practices to prevent or mitigate these disruptions [33].

In the context of sustainable supply chain management, suppliers are increasingly expected to comply with environmental and social standards. This can involve implementing green practices in their operations, such as reducing waste and emissions and ensuring fair labor practices [34]. Moreover, suppliers can play multiple roles in the supply chain, not just as providers of raw materials or components, but also as employees, entrepreneurs, and even customers, particularly in the base-of-the-pyramid (BOP) segment. This perspective expands the traditional understanding of the BOP segment as merely a customer segment, highlighting the potential for the BOP to contribute to the supply chain in various ways [34]. The choice of particular suppliers within a given supply chain is complex. A timely, and continuous, task that requires efficiency to ensure it is cost-effective to the business practice and ultimately suppliers lead to improved quality production. Optimal supplier choice affects not only product quality but also the formulation of its price and quality [35]. In recent years, the concept of a sustainable closed-loop supply chain has emerged and incorporates the impacts of backup suppliers and lateral transshipment/resupply on the supply chain design. This approach aims to decrease the shortage that may occur during the transmission of produced goods in the network, thereby enhancing the resilience of the supply chain [36].

In summary, suppliers play a fundamental role in the supply chain, with their responsibilities extending beyond the provision of raw materials or components to include aspects such as product innovation, risk management, and sustainability. A clear understanding of the roles of suppliers in the supply chain is crucial for managing and optimizing the supply chain.

3.2 Manufacturers in the Supply Chain: An Integral Role

The supply chain is considered a network of interconnected links within a business, industry, or sector that ultimately determines the production and provision of products and services required by end customers. It is a complex system. At the heart of this system are manufacturers, who play a pivotal role in transforming raw materials into finished goods. This chapter will delve into the multifaceted role of manufacturers in the supply chain, drawing upon recent academic literature to provide a comprehensive understanding of their responsibilities and their impact on the overall supply chain. The primary role of manufacturers is the production of goods. They are the entities that take raw materials and, through a series of processes, transform them into finished products [37]. This could involve anything from assembling parts to creating a car to baking ingredients to produce bread. This transformation process is the core function of manufacturers and the reason for their existence in the supply chain. However, the role of manufacturers extends far beyond the production process. They are also responsible for ensuring that the products they produce meet certain quality standards. This involves testing products, inspecting materials, and monitoring production processes to ensure that the final product is free from defects and meets the specifications set by the company or industry standards [37]. This quality control function is crucial as it directly impacts the reputation of the manufacturer and the satisfaction of the end customer. In addition to production and quality control, manufacturers also play a crucial role in managing production costs. They need to balance the cost of raw materials, labor, and overheads with the need to produce goods that are competitively priced in the market. This often involves finding ways to improve efficiency and reduce waste in the production process [38]. The ability to manage costs effectively is a key determinant of a manufacturer's profitability and competitiveness.

Moreover, manufacturers are responsible for managing the inventory of raw materials as well as the work-in-progress, and finished goods, which involves forecasting demand, scheduling production, and coordinating with suppliers and distributors [39]. Effective inventory management is essential to prevent stockouts or overstocking, both of which can have significant financial implications. Furthermore, manufacturers often work closely with suppliers to ensure a steady supply of raw materials. This can involve negotiating contracts, managing orders, and resolving any issues that arise [40]. The relationship between manufacturers and suppliers is a critical aspect of the supply chain, as any disruptions in the supply of raw materials can have a significant impact on the production process. Importantly, in many industries, manufacturers are also responsible for product innovation. This can involve researching and developing new products, improving existing products, or finding new ways to produce goods more efficiently [38]. Innovation is a key driver of competitive advantage and is increasingly important in today's rapidly changing business environment. Manufacturers play a critical and multifaceted role in the supply chain. Their responsibilities extend beyond the production process to include quality control, cost management, inventory management, supplier relationships, and innovation. Understanding the role of manufacturers in the supply chain is crucial for managing and optimizing the supply chain.

3.3 Distributors in the Supply Chain: The Bridge to the Market

Distributors, often referred to as the bridge between manufacturers and consumers, play a crucial role in the supply chain. They are responsible for the storage, transportation, and delivery of goods from manufacturers to retailers or directly to consumers. Their performance and efficiency significantly impact the overall effectiveness of the supply chain. Distributors are primarily responsible for the distribution of goods. They manage the logistics of getting products from manufacturers to the market, ensuring that goods are delivered in the right quantities, time, and condition [41]. This involves tasks such as inventory management, order processing, transportation management, and customer service. In addition to their logistics role, distributors often provide value-added services such as product customization, marketing support, and after-sales service. They can also play a role in gathering market information and providing feedback to manufacturers, helping them to better understand and respond to market trends and customer needs [42].

Distributors also play a critical role in managing supply chain risks, particularly those related to logistics and transportation. They need to plan and implement contingency measures to deal with potential disruptions such as transportation delays, inventory shortages, or changes in demand [43]. In the context of the COVID-19 pandemic, the role of distributors in the healthcare supply chain has been highlighted. They have been instrumental in ensuring the timely delivery of essential medical supplies, demonstrating the importance of resilience and adaptability in the face of unexpected disruptions [44]. Moreover, with the increasing emphasis on sustainability in supply chain management, distributors are expected to adopt green practices in their operations. This can involve measures such as optimizing transportation routes to reduce fuel consumption, using environmentally friendly packaging materials, and implementing waste reduction and recycling programs [43]. Distributors play a vital role in the supply chain, serving as the bridge between manufacturers and the market. Their responsibilities extend beyond logistics to include value-added services, risk management, and sustainability. Understanding the role of distributors in the supply chain is crucial for managing and optimizing the supply chain.

3.4 Retailers in the Supply Chain: The Final Link

Retailers, often the final link in the supply chain, play a critical role in delivering goods to the end consumer. They are responsible for the sale of goods, often in small quantities, to the consumer. Their performance and efficiency significantly impact the overall effectiveness of the supply chain. Retailers are primarily responsible for the sale of goods. They manage the interface with the end consumer, ensuring that goods are available in the right quantities, time, and condition. This involves tasks such as inventory management, order processing, customer service, and marketing [45]. In addition to their sales role, retailers often provide value-added services such as product customization, after-sales service, and gathering market information. They also provide feedback to manufacturers, helping them to better understand and respond to market trends and customer needs [46]. Retailers also play a critical role in managing supply chain risks, particularly those related to inventory management and demand forecasting. They need to plan and implement measures to deal with potential disruptions such as demand fluctuations, inventory shortages, or changes in consumer preferences [46].

In the context of the COVID-19 pandemic, the role of retailers in the healthcare supply chain has been highlighted. They have been instrumental in ensuring the timely delivery of essential medical supplies, demonstrating the importance of resilience and adaptability in the face of unexpected disruptions [45]. Moreover, with the increasing emphasis on sustainability in supply chain management, retailers are expected to adopt green practices in their operations. This can involve measures such as reducing waste, promoting recycling, and selling environmentally friendly products [45].

Furthermore, retailers are increasingly involved in the recycling process, contributing to the development of a closed-loop supply chain. This involves collecting used products from consumers and returning them to the supply chain, either by selling them as second-hand goods or by sending them back to manufacturers for remanufacturing [46]. Retailers play a vital role in the supply chain, serving as the final link between manufacturers and consumers. Their responsibilities extend beyond sales to include value-added services, risk management, and sustainability. Understanding the role of retailers in the supply chain is crucial for managing and optimizing the supply chain.

3.5 Customers in the Supply Chain: The Ultimate Recipient

Customers, often the ultimate recipients in the supply chain, play a critical role in shaping the supply chain's operations. They are the end-users of the goods and services produced and distributed by the supply chain. Their preferences, behaviors, and feedback significantly impact the overall effectiveness of the supply chain. Customers are primarily responsible for the consumption of goods and services and are referred to as the destination of the supply chain as their demand drives the production, distribution, and sales activities of the supply chain. This involves aspects such as purchasing behavior, product preferences, and feedback on product quality and service [41]. In addition to their consumption role, customers often provide valuable feedback and market information. They can play a role in shaping product development, marketing strategies, and service improvements by providing feedback on their needs, preferences, and experiences [46]. Customers also play a critical role in managing supply chain risks, particularly those related to demand fluctuations and changes in consumer preferences. Their purchasing behavior can be influenced by various factors, including price, product quality, brand reputation, and external factors such as economic conditions and social trends [46].

In the context of the COVID-19 pandemic, the role of customers in the supply chain has been highlighted. Their changing needs and behaviors, driven by factors such as lockdown measures and health concerns, have led to significant shifts in supply chain operations, including increased demand for online shopping and home delivery services [47]. Moreover, with the increasing emphasis on sustainability in supply chain management, customers are playing a growing role in driving sustainable practices. Their demand for environmentally friendly products and their willingness to support companies with sustainable practices are influencing companies to adopt green practices in their operations [48]. Customers play a vital role in the supply chain, serving as the ultimate recipient of the goods and services produced by the supply chain. Their responsibilities extend beyond consumption to include providing feedback, managing risk, and driving sustainability. Understanding the role of customers in the supply chain is crucial for managing and optimizing the supply chain.

4 Herbal Medicine Industry Development: Status and Trends

The HMI represents a significant segment of the global healthcare framework. It involves the use of whole plants, plant parts, or extracts that may be consumed wholly, used to prepare a concussion or infusion, or applied to the ailing body parts to treat or prevent diseases and enhance overall health and wellbeing. In recent years, the industry has witnessed a resurgence, fueled by an increasing consumer preference for natural and organic remedies, a growing awareness of the potential side effects of synthetic drugs, and a renewed interest in traditional and alternative medicine systems [49]. The importance of the HMI is underscored by its vast potential in addressing a multitude of health conditions, its role in healthcare systems, especially in low- and middle-income countries, and its contribution to economic development [49]. The industry is not only a source of healthcare but also a provider of livelihoods and a contributor to biodiversity conservation [49]. Consumer satisfaction is a critical aspect of the industry, influenced by factors such as perceived safety, service quality, convenience, and pricing [50]. As the industry grows, so does the need for quality control and standardization of herbal extracts or products to ensure their safety, quality, and efficacy [49].

4.1 Brief Historical Context

The use of plants for healing purposes is as old as human history and origin and not only predates modern medicine but is considered the foundation of the practice. The medicinal value of these plants is linked to their phytochemical constituents. Many old and new conventional medicine drugs are from plant sources which is a testament to the enduring value of medicinal plants. Aspirin, for instance, was developed from compounds found in the bark and leaves of the willow tree. Similarly, the heart medicine digoxin was derived from foxglove. Quinine, which is used to treat malaria, is derived from the bark of the *Cinchona* tree species, while morphine is derived from the opium poppy plant (*Papaver somniferum*).

Herbal medicine has a rich history that spans different cultures and traditions. In ancient Egypt, one of the earliest civilizations to have a structured medical system, herbs were used extensively for their medicinal properties. Papyrus scrolls from as far back as 1500 BC provide evidence of an organized medical system, where physicians used herbs like garlic, juniper, cannabis, aloe, and mandrake to treat ailments. These ancient Egyptian practices influenced Greek and Roman medicine and had a significant impact on the later development of Western medicine. In the East (Orient), traditional medicine systems like Ayurveda in India and Traditional Chinese Medicine have a long history of using herbs for treatment. These systems have a holistic approach, viewing the body as an interconnected whole and using herbs to restore balance. For instance, Ayurveda, which dates back over 3000 years, uses a wide variety of plants like turmeric, neem, and ashwagandha for their therapeutic properties [51]. In Traditional Chinese Medicine, which has a history of over 2000 years, herbs are a fundamental element. The Shen Nong Ben Cao Jing, a classic Chinese text on materia medica compiled around 200–300 AD, records the use of 365 medicinal plants. Today, herbs like ginseng, goji berry, and astragalus are widely used in Chinese medicine [51].

In more recent times, the use of herbal medicine has seen a resurgence. This is driven by factors such as the rising cost of prescription medications, side effects of synthetic drugs, and a growing interest in natural remedies. Today, herbal medicine is not only used for healthcare but is also a significant contributor to economic development and biodiversity conservation [52]. Despite the long history and widespread use, the HMI faces challenges such as standardization, quality control, and safety regulations. However, advancements in technology, such as the development of electrospinning technology for incorporating herbal medicine into nanofibers, offer new possibilities for the industry [53]. The history of herbal medicine is a testament to the enduring value of nature's pharmacy. As we move forward, it is crucial to integrate this traditional wisdom with modern scientific methods to ensure the safety, efficacy, and sustainability of herbal medicine.

4.2 Current State of the Herbal Medicine Industry

4.2.1 Market Size and Key Players

The HMI, a significant segment of the global healthcare sector, has been enjoying substantial growth over the past few years that is likely driven by a confluence of factors, including an increasing consumer preference for natural and organic remedies, a growing awareness of the potential side effects of synthetic drugs, and a renewed interest in traditional and alternative medicine systems.

The market size of the HMI is challenging to estimate due to its diverse nature, encompassing everything from small-scale local businesses to multinational corporations. However, various market research reports suggest that the industry is worth billions of dollars globally, with a steady annual growth rate. This growth is expected to continue as more consumers turn to herbal remedies for their health needs. Key players in the industry range from traditional herbal medicine practitioners who have been practicing for generations to modern companies that combine traditional knowledge with scientific research to produce and distribute herbal products on a large scale. These companies operate in various segments of the industry, including cultivation, extraction, processing, and distribution of herbal medicines. For instance, in India, *Taverniera cuneifolia*, a potent substitute for Licorice, is used extensively for its medicinal properties. The plant has expectorant, anti-ulcer, anti-inflammatory, blood purifier, wound healing, etc. properties. Recent research has focused on identifying specific functional genes involved in the biosynthesis of essential secondary metabolites in this plant, highlighting the role of scientific research in advancing the HMI [54]. However, it's important to note that the HMI is not without its challenges. Issues such as quality control, standardization of products, and regulatory hurdles pose significant challenges to the growth and development of the industry. It is crucial to understand these challenges and work toward solutions that ensure the safety, efficacy, and sustainability of herbal medicine.

4.2.2 Consumer Trends and Demands

Consumer trends in the HMI are shaped by a variety of factors, including health and wellness trends, cultural and traditional beliefs, and the perceived benefits and risks of herbal versus synthetic medicines.

1. **Preference for Natural Products**: There is a growing consumer preference for natural and organic remedies [55, 56]. This trend is driven by increasing awareness of the potential side effects of synthetic drugs and a desire for holistic and preventive healthcare approaches.
2. **Personalized Herbal Treatments**: Consumers are increasingly interested in personalized herbal treatments that are tailored to their specific health needs and conditions. This trend is facilitated by advances in technology and research, which allow for more precise customization of herbal remedies.
3. **Sustainability and Ethical Sourcing**: Herbal medicine consumers are becoming more conscious of the environmental and social impacts of the herbal products they consume. There is a growing demand for herbal products that are sustainably sourced and produced ethically.
4. **Quality and Safety**: As the HMI grows, so does consumer demand for high-quality and safe products. Consumers are looking for products that are tested for safety and efficacy, and that meet regulatory standards.
5. **Education and Information**: Consumers are seeking more information about herbal medicines, including their uses, benefits, and potential risks. There is a demand for reliable and accessible sources of information, as well as education about how to use herbal medicines safely and effectively [57].
6. **Brand Awareness and Preference**: In some markets, such as India, there is a growing awareness and preference for specific brands of herbal personal care products [58].

These trends reflect a broader shift toward more natural, personalized, and conscious consumption in the healthcare sector. They present both opportunities and challenges for the HMI and will likely continue to shape the industry in the coming years.

4.2.3 Regulatory Environment

The regulatory environment for the HMI is complex and varies by country and region. In many places, herbal medicines are regulated as dietary supplements rather than drugs and are not subjected to the same rigorous testing and quality control standards as conventional pharmaceuticals. However, there is a growing push for stricter regulations to ensure the safety and efficacy of herbal products, as well as to combat the issue of counterfeit or adulterated products in the market [59]. Standardization of herbal products is a critical aspect of these regulations. For instance, herbal antihypertensive formulations are being standardized according to Ayurvedic Pharmacopeia and WHO guidelines to provide safe and effective medicines to patients [60]. Supporting local pharmaceutical manufacturing, including the HMI, is also seen as a significant step toward reducing the cost of medical bills [61]. Furthermore, understanding the regulatory networks of herbal medicine biosynthesis, such as ginsenoside biosynthesis in ginseng, is crucial for maintaining the quality and efficacy of herbal products [62].

4.3 Key Developments in the Herbal Medicine Industry

The HMI has witnessed several significant developments in recent years, particularly in the areas of disease treatment, consumption trends, and marketing strategies. This review highlights some of these key developments based on recent scientific literature.

4.3.1 Therapeutic Applications of Herbal Medicine

Recent research has underscored the potential of herbal medicine in treating complex diseases. For instance, a study by Liu et al. [53] highlighted the role of Chinese herbal medicine and its active compounds in treating diabetic and kidney diseases. The study suggested that these herbal medicines could ameliorate diabetic kidney injury by regulating autophagy, a process that maintains cellular homeostasis and energy balance [53]. Similarly, a study by Li et al. [43] discussed the potential of herbal medicine in treating atherosclerosis, a major cause of cardiovascular disease. The researchers proposed that herbal medicines could help restore mitochondrial function and intestinal microbiota disorders, offering new insights into the prevention and treatment of atherosclerosis [43].

4.3.2 Consumption Trends in Herbal Medicine

A survey on the consumption of herbal medicine in Korea revealed interesting trends in the industry. The study by Park et al. [63] found that the consumption of herbal medicine and the size of the HMI has continued to expand. This growth was attributed to the large-scale branding of Korean Medicine institutions and the expansion of health insurance coverage [63].

4.3.3 Marketing Strategies in the Herbal Medicine Industry

The development and marketing of new herbal medicine products have also seen significant advancements. A study by Ganeshfit Company [64] discussed the development of a marketing strategy for a new anti-inflammatory herbal medicine. The researchers emphasized that the development of new herbal medicine products requires a comprehensive marketing strategy, including market segmentation, targeting, positioning, and the marketing mix (Ganeshfit Company, [64]). In summary, these developments highlight the diverse applications of herbal medicine in treating various diseases, the growing acceptance of herbal medicine in healthcare systems, and the importance of strategic marketing in the HMI. As the industry continues to evolve, it will be crucial to stay abreast of these developments to leverage opportunities and address challenges effectively.

5 Potential and Actual Supply Chain Issues Within the Herbal Medicine Industry

Some issues in the herbal medicine supply chain include the following.

5.1 Distribution and Quality Control

The distribution process is a critical component of integrated product SCM in the HMI. This process involves the processing, storage, and distribution of high-quality herbal products, making it a crucial aspect of the industry. However, the distribution of counterfeit or substandard products by unauthorized or unregistered distributors poses a significant challenge. These fake products not only undermine the integrity of the HMI but also pose serious health risks to consumers [65]. In addition to distribution, quality control is another significant issue in the HMI. The quality of herbal products is influenced by various factors, including the quality of raw materials, manufacturing processes, and storage conditions. For instance, the formulation of herbal tea infusions with botanical extracts presents several challenges, such as sourcing ingredients in appropriate quantity and quality, as well as developing quality control methods and addressing processing constraints like hygroscopicity, homogeneity of distribution, solubility, packaging machinability, and dispersibility [66]. Furthermore, the development of herbal cosmeceuticals in developing countries faces several difficulties. These include the lack of trained personnel with entrepreneurial skills, low levels of public-private partnerships, regulatory barriers, unavailability of accurate methods for the characterization/authentication of raw materials, unsustainable collection practices of medicinal plants, quality control issues, insufficient manufacturing capacity, and lack of financing [67]. These issues highlight the need for robust quality control and distribution systems in the HMI. Addressing these issues requires a comprehensive approach that includes strengthening regulatory frameworks, enhancing public-private partnerships, investing in research and development, and promoting sustainable practices.

5.2 Supply Chain Design and Sustainability

In the design of supply chains, different goals are considered. Sustainability in supply chains plays an important role in goal setting to reduce economic, social, and environmental risks. Therefore, it promotes optimization of and stability within the supply chain network. In addition, a lesser-known aspect of sustainability, the political aspect, has been added to the previous aspects [68]. The design of a sustainable supply chain involves the consideration of various factors, including economic, social, environmental, and political aspects. For instance, in the case of the supply chain for COVID-19 drugs, a mathematical model was developed to optimize the stability of the supply chain network. This model considers multiple functional objectives including economic, political, and environmental goals for a metaheuristic algorithm designed to find an optimal configuration [68]. Whereas the green closed-loop supply chain network (GCLSCN) mainly considers trade-offs between environmental and economic aspects. This model was used during the COVID-19 pandemic to address hygiene costs like disinfection and sanitizer costs, as well as personal protective equipment (PPE) costs, cost of COVID-19 tests, and education, medicines, and vaccination costs [47]. In the context of the HMI, the design of a sustainable supply chain is crucial. The supply chain should not only ensure the efficient distribution of herbal products but also promote sustainable practices, such as the sustainable harvesting of medicinal plants. A study on the dual trade of *Nardostachy jatamansi* and *Fritillaria cirrhosa* and Tibetan people's harvesting behavior revealed that the sustainability of the former species was largely dependent on the latter one (Jingjing [69]).

5.3 Physical Internet and Supply Chain Management

The Physical Internet (PI) is a recent innovation in logistics and supply chain management (LSCM) that aims to improve the economic, environmental, and social ways that physical objects are designed, supplied, and used. The PI is described as "a global logistics system based on the interconnection of logistics networks by a standardized set of collaboration protocols, modular containers, and smart interfaces for increased efficiency and sustainability" [70]. Considering that everything in the physical world, in the future would be replicated in the digital space, PI would play a greater role [71]. In the context of the HMI, the concept of PI can potentially revolutionize supply chain management. By leveraging the principles of PI, the industry can enhance the efficiency and sustainability of its supply chains. This can involve the use of standardized protocols and smart interfaces to facilitate the global movement and distribution of herbal products. Furthermore, the use of digital technologies can enable the replication of physical supply chain processes in the digital space, thereby enhancing visibility, traceability, and control.

6 Sustainable Supply Chain in Herbal Medicine Industry

The incorporation of a formal supply chain system into the HMI has the potential to greatly improve the value and benefits of the sector. The proposed HMI supply chain (Fig. 1) will have the following six core parts:

- Sustainable Cultivation and Harvesting of Herbal Resources
- Sustainable Manufacturing of Herbal Medicine Products
- Green Distribution Process for Herbal Medicine Products
- Eco-friendly Wholesalers, Retailers, and Vendors of Herbal Medicine Products
- Sustainable Herbal Medicine Utilization
- Herbal Medicine Waste Recovery

6.1 Sustainable Cultivation and Harvesting of Herbal Resources

The proposed first component of this sustainable herbal medicine supply chain will involve the implementation of sustainable agricultural practices to ensure the long-term availability of medicinal plants. Sustainable cultivation and harvesting of herbal resources are crucial to the preservation of these resources and the environment. It involves practices such as in situ and ex situ conservation, cultivation practices, and good agricultural practices [72]. In situ conservation refers to the conservation of species in their natural habitats, while ex situ conservation involves the conservation of species outside their natural habitats, for example, in botanical gardens or seed banks [72]. Cultivation practices refer to the growing of medicinal plants in a controlled environment to reduce the pressure on wild populations. Good

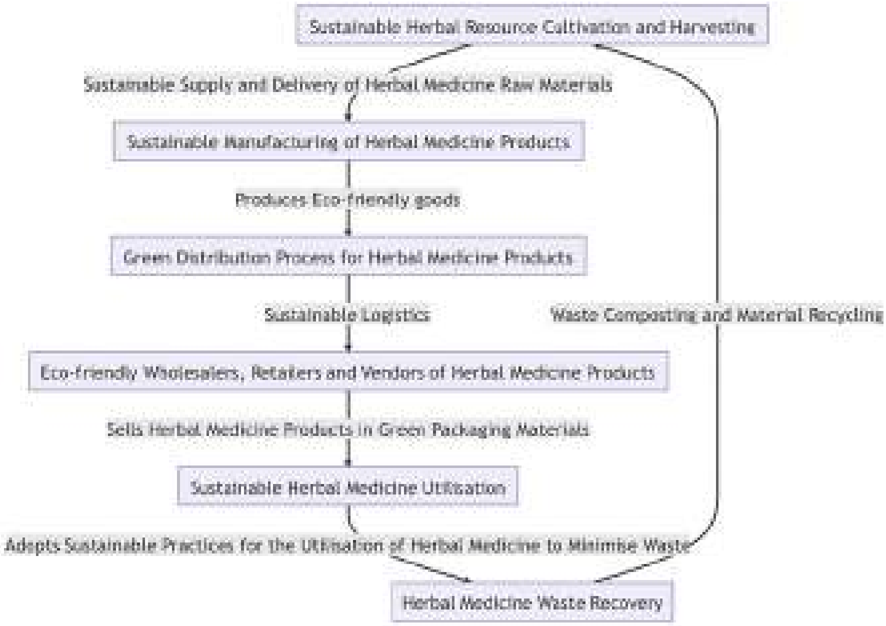

Fig. 1 Proposed herbal medicine sustainable supply chain

agricultural practices involve the application of methods and techniques that minimize environmental impacts, maintain the health and welfare of workers, and ensure the quality and safety of herbal products [72].

Moreover, sustainable cultivation and harvesting also involve the application of biotechnical approaches such as tissue culture, micropropagation, synthetic seed technology, and molecular marker-based approaches. These techniques can improve the yield and modify the potency of medicinal plants, thereby enhancing their therapeutic effectiveness [72]. In the context of herbal medicine, sustainable cultivation, and harvesting are particularly important. For example, Barbados aloe (*Aloe vera* (L.) Burm. F.), a plant traditionally used for healing in natural medicine, is now attracting great interest in the global market due to its bioactive chemicals. The most important factors affecting aloe production include propagation techniques, sustainable agronomic practices, and efficient post-harvesting and processing systems [73]. Sustainable cultivation and harvesting of herbal resources are critical components of a sustainable herbal medicine supply chain. They ensure the long-term availability of medicinal plants and contribute to the preservation of the environment.

6.2 Sustainable Manufacturing of Herbal Medicine Products

The second component of the proposed sustainable herbal medicine supply chain will involve the application of sustainable practices in the manufacturing process to ensure the production of eco-friendly goods. Sustainable manufacturing of herbal medicine products is a critical aspect of the supply chain. It involves the use of environmentally friendly methods and technologies to transform raw herbal materials into finished products. This process should minimize waste, reduce energy consumption, and limit the use of non-renewable resources [74].

In the context of herbal medicine, sustainable manufacturing can involve the use of innovative process design methods like Quality by Design (QbD) and quality control in the form of Process Analytical Technology (PAT). These methods can help to ensure the quality and safety of herbal products [74]. Moreover, sustainable manufacturing can also involve the use of standardized laboratory equipment combined with physicochemical predictive process modeling. These techniques can improve the efficiency of the manufacturing process and reduce the cost of production [74]. For example, in the production of *Indigo naturalis*, a traditional Chinese medicine used for various ailments, sustainable manufacturing practices are crucial. The manufacturing process involves the use of environmentally friendly methods to transform the raw Indigo naturalis into a finished product. This process minimizes waste and reduces energy consumption (Yang [75]). Sustainable manufacturing of herbal medicine products is a critical component of a sustainable herbal medicine supply chain. It ensures the production of eco-friendly goods and contributes to the preservation of the environment.

6.3 Green Distribution Process for Herbal Medicine Products

The proposed third component of the sustainable herbal medicine supply chain is a critical aspect that requires strategic planning and implementation. This involves the sustainable logistics of distributing herbal medicine products using low-carbon emission processes. To enhance the sustainability of the herbal medicine supply chain, it is proposed that companies should adopt green distribution strategies. This could involve the use of vehicles that emit fewer greenhouse gases or the optimization of delivery routes to reduce fuel consumption and emissions. This not only contributes to environmental sustainability but also can lead to cost savings in the long run [76].

In the context of the COVID-19 pandemic, the importance of green distribution has been highlighted. Companies should consider using digital platforms to facilitate the distribution of herbal medicine products. This can reduce the need for physical transportation, thus reducing carbon emissions [77]. Moreover, companies should also consider collaborating with local suppliers and distributors. This can reduce the distance that products need to be transported, thus reducing carbon emissions. In addition, companies should also consider using environmentally friendly packaging materials to further reduce the environmental impact [78]. Finally, the adoption of green distribution strategies is a critical component of a sustainable supply chain for herbal medicine products. It not only contributes to environmental sustainability but also can lead to cost savings and enhanced customer satisfaction.

6.4 Eco-friendly Wholesalers, Retailers, and Vendors of Herbal Medicine Products

The fourth proposed component of the sustainable herbal medicine supply chain will involve selling herbal medicine products in green packaging materials that minimize loss and environmental damage.

Eco-friendly wholesalers, retailers, and vendors play a crucial role in the sustainable supply chain of herbal medicine. They are the link between the manufacturers and the consumers, and their practices significantly impact the overall sustainability of the supply chain. One of the key practices is the use of green packaging materials. Traditional packaging materials often lead to significant environmental pollution due to their non-biodegradable nature. Green packaging, on the other hand, is made from renewable, biodegradable materials, which significantly reduces the environmental impact [79]. Moreover, eco-friendly wholesalers, retailers, and vendors can also contribute to sustainability by reducing waste. This can be achieved by implementing practices such as just-in-time inventory management, which ensures that only the necessary number of products is in stock, thereby reducing waste from expired or unsold products [80].

Furthermore, these stakeholders can also promote sustainability by educating consumers about the importance of sustainable practices in the use of herbal medicine. This can include information about the sustainable sourcing of the products, the environmental benefits of using green packaging, and the importance of proper disposal of used products [80]. Eco-friendly wholesalers, retailers, and vendors are a critical component of a sustainable herbal medicine supply chain. Their practices significantly impact the overall sustainability of the supply chain, and they play a crucial role in promoting sustainability to consumers.

6.5 Sustainable Herbal Medicine Utilization

The fifth component of the proposed sustainable herbal medicine supply chain will involve adopting sustainable practices for the utilization of herbal medicine to minimize waste and ensure the efficient use of resources. Sustainable utilization of herbal medicine is a critical aspect of the supply chain. It involves the efficient use of medicinal plants to ensure that the benefits are maximized while the negative impacts on the environment and biodiversity are minimized [81]. One of the key aspects of sustainable utilization is the efficient use of medicinal plants. This involves using all parts of the plant effectively and reducing waste. For instance, the Garo tribe in Bangladesh, which is heavily dependent on natural resources, has demonstrated how to effectively use various parts of plants for food, energy, timber, and healthcare. Their practices reflect a deep understanding of the plants and their uses, which contributes to the sustainable utilization of these resources [81]. Another important aspect is the use of traditional knowledge in the utilization of herbal medicine. Traditional knowledge, which has been accumulated over generations, often contains valuable information about the sustainable use of medicinal plants. For example, the Garo tribe's practices are based on their indigenous knowledge, which has been passed down through generations. This knowledge can be an important tool for promoting the sustainable utilization of herbal medicine [81]. Furthermore, sustainable utilization also involves the responsible use of herbal medicine. This includes following recommended dosages and avoiding overuse, which can lead to the depletion of medicinal plant resources. It also involves promoting the use of sustainable and eco-friendly practices among consumers [82]. Sustainable herbal medicine utilization is a critical component of a sustainable herbal medicine supply chain. It involves the efficient and responsible use of medicinal plants, the application of traditional knowledge, and the promotion of sustainable practices among consumers.

6.6 Herbal Medicine Waste Recovery

The final component of the proposed sustainable herbal medicine supply chain involves the management of waste produced by the HMI. One of the ways this can be achieved is through the process of pyrolysis. Pyrolysis is a promising method to dispose of biomass and organic waste such as herbal medicine waste. A study by Lee et al. [83] applied an activated carbon-supported Pt catalyst and carbon dioxide (CO_2) to the pyrolysis of real herbal medicine waste. The study found that the generation of benzyl species, which are harmful to the environment and human health, was suppressed. Another study by Mi et al. [84] also used pyrolysis to create activated carbon from Chinese herbal medicine waste. The study found that herbal medicine waste is a good precursor material for preparing activated carbon. In addition to pyrolysis, the recovery of herbal medicine waste can also be achieved through the inhibition of harmful chemicals. A study by Oh et al. [85] found that several single herbal medicines have the potential to inhibit the activation of harmful chemicals in an in vitro AKI-mimicked condition. Lastly, a study by Jin et al. [77] found that the potential mechanisms involved in the treatment of COVID-19-related pulmonary fibrosis and SARS-CoV-2 infection involve multiple components, targets, and pathways, indicating the potential of herbal medicine waste in the treatment of diseases. In summary, the recovery of herbal medicine waste is a crucial component of a sustainable herbal medicine supply chain. It involves the management of waste through methods such as pyrolysis and the inhibition of harmful chemicals. It also involves the potential use of herbal medicine waste in the treatment of diseases.

7 Herbal Medicine Supply Chain Monitoring System

There is a need for a supply chain monitoring system for HMI to ensure QbD and improve relationships and experience among and between the different HMI value chain players (Fig. 2).

1. **Sustainable Management and Conservation of Herbal Resources**: This is the first and foundational step in the supply chain. It involves the creation of policies and strategies that promote the sustainable use and conservation of medicinal plant resources. These policies should be based on scientific research and best practices in the field. They should address issues such as overharvesting, habitat conservation, and the promotion of biodiversity. Training programs should be

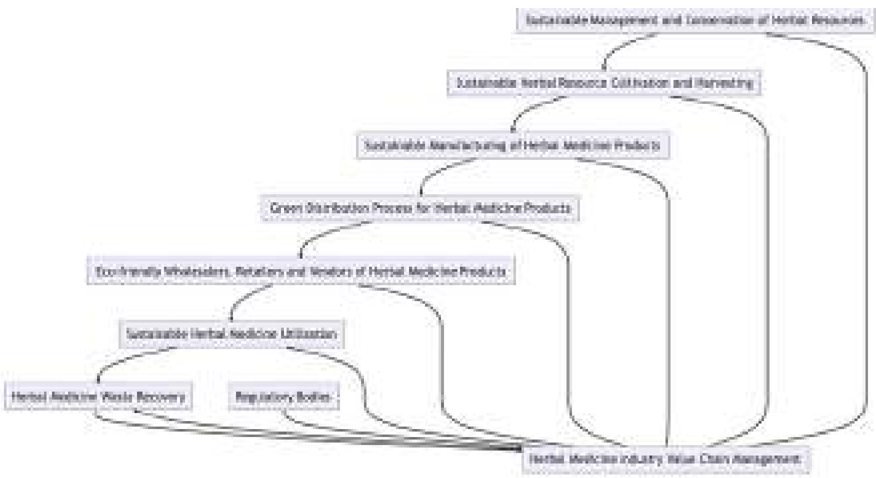

Fig. 2 Proposed herbal medicine industry supply chain monitoring system

developed to educate stakeholders, including farmers and manufacturers, about these policies and how to implement them. Research initiatives should be undertaken to continually improve these policies and practices. Regulatory bodies should regularly review these policies, training materials, and research findings to ensure they are effective and up-to-date.

2. **Sustainable Herbal Resource Cultivation and Harvesting**: This stage involves the cultivation and harvesting of medicinal plants in a sustainable manner. This includes practices such as crop rotation, organic farming, and the use of sustainable irrigation systems. Farmers should be trained in these practices and provided with the necessary resources and support. Regulatory bodies should conduct regular field inspections to ensure these practices are being followed. They should also review the training provided to farmers to ensure it is effective and up to date.
3. **Sustainable Manufacturing of Herbal Medicine Products**: At this stage, the harvested plants are processed into herbal medicine products. The manufacturing process should be designed to minimize waste and reduce environmental impact. This could involve the use of energy-efficient machinery, the recycling of waste materials, and the minimization of water use. Regulatory bodies should conduct regular facility inspections to ensure these practices are being followed. They should also review the manufacturing processes to ensure they meet environmental standards.
4. **Green Distribution Process for Herbal Medicine Products**: This stage involves the distribution of the manufactured products. The distribution process should be designed to minimize carbon emissions and reduce environmental impact. This could involve the use of fuel-efficient vehicles, the optimization of delivery routes, and the use of renewable energy sources. Regulatory bodies should review logistics processes and transportation methods regularly to ensure they are sustainable.
5. **Eco-friendly Wholesalers, Retailers, and Vendors of Herbal Medicine Products**: At this stage, the products are sold to consumers. The packaging used should be eco-friendly and designed to minimize loss and environmental damage. This could involve the use of biodegradable or recyclable materials, the minimization of packaging, and the promotion of reusable containers. Regulatory bodies should conduct regular inspections of packaging materials and review the practices of wholesalers, retailers, and vendors to ensure they are sustainable.
6. **Sustainable Herbal Medicine Utilization**: This stage involves the use of herbal medicine products by consumers. Consumers should be educated about the sustainable use of these products to minimize waste. This could involve the provision of information about dosage, storage, and disposal. Regulatory bodies should conduct regular surveys or inspections to assess consumer knowledge and behavior.
7. **Herbal Medicine Waste Recovery**: The final stage involves the management and disposal of waste produced from herbal medicine. Waste management practices should be environmentally friendly and comply with waste management regulations. This could involve the composting of organic waste, the recycling of packaging materials, and the safe disposal of hazardous waste. Regulatory bodies should conduct regular inspections of waste management practices to ensure they are sustainable.

8. **Herbal Medicine Industry Value Chain Management**: This is the overarching management system that oversees the entire value chain. It ensures the implementation of sustainable practices at each stage and compliance with all relevant laws, regulations, and standards. This system should be transparent and accountable, with regular audits and reviews conducted by regulatory bodies.
9. **Regulatory Bodies**: These organizations play a crucial role in ensuring the sustainability of the supply chain. They have the authority to enforce compliance with laws, regulations, and standards, and to penalize non-compliance. They also have a responsibility to provide guidance and support to stakeholders, promote best practices, and facilitate continuous improvement in the industry.

By understanding each stage of the value chain and the role of regulatory bodies, businesses can better manage their operations to create value in an environmentally friendly manner. This not only benefits the environment but also enhances the business's reputation and competitiveness in the market. Regular monitoring and evaluation by regulatory bodies will ensure that the plan is being followed and that any necessary adjustments are made promptly.

8 Benefits of Sustainable Supply Chain Development and Management Within the Herbal Medicine Sector

There are numerous benefits to developing and managing a sustainable supply chain within the herbal medicine sector. These benefits span across environmental, social, and economic dimensions, contributing to the overall sustainability of the industry. Here are some key benefits:

1. **Environmental Stewardship**: A sustainable supply chain in the herbal medicine sector emphasizes the responsible use and conservation of natural resources. This involves practices such as organic farming, crop rotation, and sustainable irrigation systems that are designed to minimize environmental impact. An example is organic farming, which avoids the use of synthetic agrochemicals that can harm soil health and biodiversity. Crop rotation can help to maintain soil fertility and prevent pest outbreaks, reducing the need for chemical inputs. Sustainable irrigation systems can conserve water and reduce energy use. These practices not only help to ensure a steady supply of medicinal plants for future generations but also contribute to broader environmental goals such as climate change mitigation and biodiversity conservation.
2. **Social Responsibility**: A sustainable supply chain also promotes social equity and community well-being. This can be achieved through fair trade practices that ensure farmers and workers receive a fair price for their products and labor. This can help to improve living standards and reduce poverty in communities where medicinal plants are grown and harvested. Additionally, the promotion of traditional knowledge and practices in herbal medicine can contribute to cultural preservation and community empowerment. For instance, indigenous

communities that have been custodians of medicinal plant knowledge for generations can be recognized and compensated for their contributions, helping to maintain their cultural heritage and livelihoods.

3. **Economic Viability**: From a business perspective, a sustainable supply chain can enhance profitability and competitiveness. Efficient use of resources and waste reduction can lower operational costs. For instance, organic farming practices can improve soil health and productivity, reducing the need for costly chemical inputs. Waste reduction strategies such as composting and recycling can turn waste into valuable resources, further reducing costs. Moreover, the production of high-quality, sustainable herbal medicine products can attract a growing market of consumers who value sustainability, enhancing sales and customer loyalty. Companies that demonstrate a strong commitment to sustainability can also enhance their brand reputation, gaining a competitive edge in the market.
4. **Regulatory Compliance**: As governments and international bodies impose stricter environmental and social regulations, having a sustainable supply chain can help companies in the herbal medicine sector to comply with these regulations. This can prevent legal issues and financial penalties that can arise from non-compliance. Moreover, companies that proactively adopt sustainable practices can influence regulatory frameworks and position themselves favorably for potential future regulations.
5. **Risk Management**: A sustainable supply chain can help to mitigate a variety of risks. Environmental risks such as resource depletion and climate change can disrupt supply chains, but these can be mitigated through sustainable resource management and climate adaptation strategies. Social risks such as labor disputes and community conflicts can be mitigated through fair trade practices and community engagement. Financial and reputational risks due to regulatory penalties or consumer backlash against unsustainable practices can be mitigated through proactive compliance and sustainability communication strategies.
6. **Innovation and Learning**: The pursuit of sustainability can stimulate innovation and learning within the organization. It will promote the development of new products, processes, and business models that are more sustainable and competitive. For instance, research and development efforts can lead to the discovery of new medicinal plants or the development of more efficient processing techniques. Learning and capacity-building initiatives can enhance the skills and knowledge of employees, enabling them to implement sustainable practices more effectively. This culture of innovation and learning can enhance the organization's adaptability and resilience in a rapidly changing world.

9 Conclusion

The development and management of a sustainable supply chain in the herbal medicine sector can yield substantial environmental, social, and economic benefits. It can contribute to the sustainability of the sector and the broader society, while also enhancing business performance and resilience. Therefore, it is a strategic imperative for any company in this sector. SCM developments in the HMI will highlight and enhance the diverse applications and intrinsic value of herbal medicine in treating various diseases and contribute to growing the acceptance and integration of herbal medicine into formal healthcare systems as well as the strategic marketing of herbal medicine products.

Abstract

The healthcare modality that capitalizes on the therapeutic and spiritual attributes of plants and is deeply rooted in indigenous people's traditions, local knowledge, and practices as well as plant resources in the locale is considered herbal medicine. This system of healthcare has been the cornerstone of various cultures globally for centuries but is currently experiencing a renaissance due to the need to incorporate sustainability considerations in plant resource management, phytochemical extraction, herbal product design and development, production processes, marketing, packaging, distribution, utilization, and waste management. Using an online survey, this chapter attempts to comprehend and discuss consumer perception and demand for sustainable herbal medicine products (HMPs) by assessing the level of consumer awareness and knowledge about sustainable HMPs as well as factors influencing consumer demand and perceptions about the efficacy and safety of HMPs. Such information will provide invaluable insights to HMP manufacturers, marketers, policymakers, and other stakeholders in the herbal medicine sector and effectively aid the incorporation of sustainability in the production, demand, supply, and consumption of HMPs. Findings suggest that personal networks and recommendations (63.2%) are the most effective channels for spreading awareness about herbal medicine, while public advertisements play a lesser role. A greater number of people continue to use and accept HMPs (74.8%) mostly due to their perceived efficacy (72.5%) and safety. Precisely, 45.1% of respondents expressed that herbal medicines perform "a bit better" than conventional medicine. Interestingly, price appears to be less significant in the decision-making process (26.5%). A substantial number of respondents (83.3%) affirmed their preference for the heightened presence of herbal medicine products in the market. The most common issue reported by respondents (65.2%) was a lack of sufficient information about HMPs. Positive consumers' perception of HMPs is mostly linked to the concept of "nature and naturalness" as well as "safety and healthiness" and "efficacy and effectiveness," while some things that respondents would like to see improved include "dosage, prescription, packaging, labelling, regulation, authentication, research, development, and safety concerns, accessibility, availability, taste and aesthetics, and support from government and non-governmental organizations." In conclusion, there is a need for more research to address pertinent sustainability issues in herbal medicine practices and HMPs that are linked to consumer perception.

Keywords

Consumer preference · Consumer demand · Herbal medicine products · Market dynamics · Supply chain management · Consumer perception · Sustainability

Abbreviations

%	Percent or percentage
COVID-19	Corona virus disease of 2019
DNA	Deoxyribonucleic acid

HCl	Hydrochloride
HMPs	Herbal medicine products
IR	Infrared
ITS2	Internal transcribed spacer 2
LCMS	Liquid chromatography-mass spectroscopy
matK	Megakaryocyte-associated tyrosine kinase
MODS	Multi-organ dysfunction syndrome
n	Number of respondents
NGOs	Nongovernmental organizations
PHWE	Pressurized hot water extraction
psbA	Photosystem II protein D1
rbcL	Ribulose bisphosphate carboxylase
SARS-CoV-2	Severe acute respiratory syndrome coronavirus 2
TEOS	Tetraethyl orthosilicate
THM	Traditional herbal medicine

1 Introduction

Herbal medicine, a healthcare modality that capitalizes on the therapeutic and spiritual attributes of plants, has been a cornerstone of various cultures globally for centuries ([1, 2]). The practice is deeply rooted in indigenous people's tradition, local knowledge, and practices as well as plant resources in the locale and has been experiencing a renaissance in recent years. Interestingly, this resurgence is largely driven by escalating consumer demand for herbal medicine products, particularly those that are sustainably sourced and produced ([3]). In addition, herbal medicine has found relevance in the treatment and management of new and existing human disease conditions including Lassa fever and COVID-19 [4]. This paradigm shift in consumer perception is catalyzing a transformation in market dynamics, necessitating novel businesses in the herbal medicine sector to recalibrate their strategies in alignment with evolving market trends and consumer preferences.

In the realm of herbal medicine, sustainability has emerged as a pivotal concept in the contemporary discourse surrounding plant resource management, extraction, product design and development, production processes, marketing, packaging, distribution, utilization, and waste management ([5, 6, 7]). This new direction requires a multidimensional approach to forge, encompassing environmental, social, and economic facets. From an environmental perspective, sustainable herbal medicine resources and products are sourced, produced, and consumed in a manner that minimizes their environmental legacy through techniques like organic farming, eschewing the use of synthetic pesticides and fertilizers, and sustainable harvesting and conservation to ensure that plant populations are not compromised ([8, 9]). On the social front, sustainable herbal medicine products foster fair and equitable relationships among all stakeholders. This includes fair trade practices, ensuring that farmers and workers receive fair remuneration for their labor and that working conditions are safe and humane. It also involves acknowledging the cultural significance of medicinal plants and respecting indigenous knowledge and rights ([10]). From an economic perspective, sustainable HMPs confer benefits to all stakeholders in the supply chain. This includes not only profits for manufacturers and retailers but also minimizing healthcare expenditures and ensuring economic stability and resilience for farming communities ([11]).

The demand for sustainable HMPs represents a significant intersection of health and sustainability trends. Modern consumers are increasingly seeking out products that not only bolster their health but also align with their values and concerns about the environment and societal well-being. In response to this demand, herbal medicine product manufacturers are implementing more sustainable practices in their production processes and offering products that are certified as organic, fair trade, or sustainably harvested. However, despite the burgeoning interest and demand for sustainable HMPs, there exists a notable gap in comprehensive research on consumer perception and demand for herbal products. Moving forward, this lacuna is likely to have significant implications for manufacturers, marketers, and policymakers involved in the production and promotion of HMPs ([12, 13]). Hence, understanding consumer perception is pivotal for manufacturers and marketers, as it is the consumers who ultimately determine the success or failure of their herbal products in the market as well as overall marketing strategies. Consumer perceptions, preferences, and purchasing behaviors in relation to herbal products shape the market dynamics. Moreover, the factors influencing consumers' decisions to purchase sustainable products are multifaceted, encompassing disease conditions, health awareness, risk perception, and perceptions of a company's environmental and social practices.

For policymakers, understanding consumer perception and demand for sustainable herbal medicine products is crucial for developing effective policies and regulations. Policymakers may use relevant instruments and mechanisms to promote the sustainable production and consumption of herbal medicine products and to avoid greenwashing and whitewashing of consumers, their products, and the environment. They can implement policies and regulations that encourage manufacturers to adopt sustainable practices and ensure the quality and safety of these products. They can also promote consumer education and awareness about the benefits of sustainable herbal medicine products).

This chapter delves into and attempts to comprehend consumer perception and demand for sustainable herbal medicine products. The objectives include:

1. Investigating the level of consumer awareness and knowledge about sustainable herbal medicine products.
2. Examining the factors influencing consumer demand for sustainable herbal medicine products.
3. Assessing consumer perceptions toward the efficacy and safety of these products.
4. Identifying the barriers and challenges consumers face in accessing these products.
5. Providing recommendations for enhancing the sustainability and consumer acceptance of herbal medicine products in Nigeria.

Attempting an understanding of consumer perception and demand for sustainable herbal medicine products is a complex yet crucial endeavor, but the findings presented in this chapter will provide invaluable insights to herbal medicine product manufacturers, marketers, policymakers, and other stakeholders in the herbal medicine sector in order to aid them in effectively promoting the sustainable production and consumption of herbal medicine products. Also, this chapter includes a review of the multifaceted world of herbal medicine products, examining their classifications, applications, production processes, and the research methodologies employed in pertinent studies.

2 Importance of Herbal Medicine Products and Herbal Medicine Practices

2.1 Herbal Medicine Products

Herbal medicine products, both branded and unbranded, have been a cornerstone of healthcare systems worldwide for centuries. Since herbal medicine began to attract big pharmaceutical companies, branded herbal products are commonly found in the Global North whereas unbranded or poorly packaged ones are found in the Global South ([14, 15]). Nonetheless, derived from plants, these herbal products serve therapeutic purposes and often act as alternatives to conventional pharmaceuticals. Herbal medicine products exhibit a diverse range of forms, usage, and branding. They can be presented in various forms such as tablets, capsules, powders, extracts, or teas, among others, and can be put together by the patient or their loved ones or purchased from the market for treating and managing diverse ailments [16, 17]. Each form has its unique advantages and is chosen based on the desired route of administration, convenience, and patient preference. Their applications are equally varied, addressing a wide spectrum of health conditions ranging from minor ailments like colds and coughs to chronic diseases such as diabetes and hypertension. Branded products, marketed with specific health claims, are subject to regulatory standards, ensuring their safety, efficacy, and quality [18]. Conversely, unbranded products are often traditional remedies passed down through generations or self-prepared mixtures, whose efficacy and safety are usually based on anecdotal evidence and personal experiences.

Maramba-Lazarte [19] highlights the pivotal role of traditional herbal medicine in healthcare, particularly in rural areas where access to conventional medicine may be limited. The study employed a qualitative approach, using interviews and focus group discussions to investigate healthcare system challenges, notably the high cost of branded and generic drugs. The findings suggest that research into traditional medicinal plants, including herbal medicine, could provide a cost-effective solution to these challenges. However, the study also emphasizes the need for quality and standardization of herbal medicine, preclinical pharmacological assessments, and clinical efficacy and safety assessments to ensure that these traditional remedies are safe and effective. The study's limitation lies in its focus on the Philippine context, which may not be representative of other countries with different healthcare systems and cultural practices. Sriharini and Syafira [20] explore the use of herbal medicine in the village of Rejowinangun. The villagers have capitalized on their inherited knowledge of herbal medicine, integrating it into a tourism-based model. The study reveals a transition from traditional usage to a tourist village concept, increasing the economic value of herbal medicines in modern society. This innovative approach not only preserves the traditional knowledge of herbal medicine but also provides a sustainable source of income for the community. However, the study's findings may not apply to other Indonesian communities or communities lacking the potential to develop a tourism-based model. In the Global North, Welz et al. [21] delve into the motivations behind the use of herbal medicine. They identify three influencing factors:

1. **Push factors**, which include dissatisfaction with conventional medicine
2. **Pull factors**, which include an attraction to herbal medicine
3. **Traditional factors** include long-standing family traditions and the cultural importance of herbal medicine

The study by Welz et al. [21] provides valuable insights into the complex interplay of factors influencing the use of herbal medicine, which could be useful for healthcare providers and policymakers in designing strategies to promote the safe and effective use of herbal medicine. However, the study does not explore the potential influence of other factors, such as economic factors, on herbal medicine usage, and its findings may not be applicable outside the German context. The study by Shah and Pokhrel [22] focused on the microbial quality and antibacterial activity of different herbal medicines. The study demonstrates the in vitro antibacterial activity of herbal medicines, suggesting their potential use in treating bacterial infections. This finding underscores the therapeutic potential of herbal medicines, which could be harnessed to address the growing problem of antibiotic resistance. However, the study's focus on microbial quality does not explore other aspects of herbal medicine usage in the Nepalese context, such as cultural beliefs, traditional practices, or economic factors.

Furthermore, the use of herbal medicine varies significantly across different cultural contexts. Factors such as community traditions, dissatisfaction with conventional medicine, and the need for culturally appropriate healthcare education influence the use of herbal medicine. However, more research is needed to explore the use of herbal medicine in other cultural contexts and to address the limitations identified in these studies. As the demand for herbal medicine continues to grow, ensuring their safety, efficacy, and quality will remain a critical area of focus in healthcare.

Nevertheless, despite the widespread use of herbal medicine, several studies have identified the issue of adulteration in herbal medicine. The adulteration of herbal medicine products is a significant concern in the field of herbal medicine. This issue is not only a matter of consumer deception but also a significant health risk, as adulterants can have harmful effects. Various studies have been conducted to detect and understand the extent of this problem, employing different methodologies and focusing on various aspects of adulteration. A study by reveals that some herbal medicines were adulterated with acetaminophen, a chemical drug. The study utilizes liquid chromatography-mass spectroscopy (LCMS) to identify the fragmentation patterns of herbal medicine. This finding underscores the need for stringent quality control and regulation in the herbal medicine industry, highlighting the potential risks associated with unregulated or poorly regulated products. However, the study's limitation is that it only tested for acetaminophen, leaving the possibility of other adulterants undetected.

In a similar vein, a study by Andawiyah et al. [23] developed an optical sensor-based test strip for detecting sibutramine HCl (hydrochloride) adulteration in traditional herbal products. Sibutramine HCl is an anti-obesity agent that has been withdrawn from the Indonesian market due to its adverse effects such as palpitations, insomnia, and cardiovascular disease. The researchers used a cellulosic paper immobilized with Dragendorff's reagent and tetraethyl orthosilicate (TEOS) as the precursor using the sol-gel method. The presence of sibutramine HCl changed the color of the test strip from yellow to orange-red, indicating adulteration. This method provided a low-cost, simple, and efficient way to detect sibutramine HCl in herbal products. However, the study only tested for sibutramine HCl, leaving the possibility of other adulterants undetected. In another study, Teshager et al. [24] investigated the association between traditional herbal medicine (THM) use and the risk of multi-organ dysfunction syndrome (MODS) in a pediatric intensive care unit in Ethiopia. The study found that patients who used THM had a threefold increased risk of MODS, suggesting the potential harm of adulterated or inappropriate use of herbal medicines. However, the study did not specifically identify the adulterants in the herbal medicines used by the patients. A different approach was taken by Balaji and Parani [25], who used DNA barcoding to authenticate single-drug herbal powders collected from markets in Tamil Nadu, India. They found that 46% of the tested samples were adulterated with taxonomically unrelated plant species. This study underscores the prevalence of adulteration in herbal medicine products and the need for effective detection methods. However, the study did not identify the specific adulterants in the herbal powders. Therefore, the adulteration of herbal medicine products is a widespread and complex issue that poses significant health risks. Various methodologies, from optical sensor-based test strips to DNA barcoding, have been employed to detect adulteration. However, these studies are limited in their ability to detect a wide range of potential adulterants, highlighting the need for comprehensive testing methods. Furthermore, more research is needed to understand the health impacts of adulterated herbal medicine products and to develop effective strategies for prevention and regulation. It is therefore paramount for this study to examine the production processes involved in the production of herbal medicine.

2.2 Production of Herbal Medicine

The production of herbal medicine products involves several steps, including cultivation, harvesting, extraction, formulation, and packaging. In a study by Sixt and Strube [26], a modern process engineering concept is provided for the extraction of traditional herbal medicines from plants. The study critically assesses traditional solvent-based percolation and compares it to pressurized hot water extraction (PHWE) as a potential alternative. The study employs a systematic process design for the extraction of hawthorn (*Crataegus*) and incorporates natural batch variability into the physicochemical process modelling concept. The findings reveal that PHWE is the best choice from both technical and economic perspectives, suggesting a potential shift in extraction methodologies for herbal medicine production. However, the study is limited by its focus on hawthorn, and the results may not apply to other herbal medicines.

In a different approach to waste management in herbal medicine production, Soetrisnanto et al. [27] discuss the use of phytoremediation, an environmentally friendly method, to reduce contaminants and nutrients in herbal medicine waste. The study posits that this waste, due to its high nutrient content, could potentially be used as a growth medium for the algae, *Spirulina*. The study employs a two-stage process, with the effluent of the first phytoremediation transferred to the second stage for the cultivation of *Spirulina*. This innovative approach to waste management not only addresses environmental concerns but also proposes a potential avenue for resource optimization. However, the study is limited by its focus on *Spirulina*, and the results may not apply to other algae or plant species.

Lastly, in a study by Liu et al. [28], the shotgun metabarcoding method is used for the molecular identification of the biological ingredients in Qingguo Wan, a herbal medicine used for treating pharyngitis. The study employs the Illumina NovaSeq platform for targeting the ITS2, psbA-trnH, matK, and rbcL sequences to survey the species composition of laboratory-made and commercial samples. The findings demonstrate that the shotgun metabarcoding method is a powerful tool for the molecular identification of the biological ingredients in herbal medicine products, suggesting a potential shift in quality control methodologies for herbal medicine production. However, the study is limited by its focus on Qingguo Wan, and the results may not apply to other herbal medicines.

In summary, the reviewed studies underscore the importance and potential of herbal medicine products in healthcare. However, they also highlight the challenges in the field, such as the high cost of branded drugs, adulteration of products, and the need for more research and stringent regulation and quality control of herbal medicines. One of the limitations in the field of herbal medicine research is the lack of innovation due to stringent regulation and approval processes. Additionally, the natural variability of herbal ingredients can pose challenges in standardizing product quality. Furthermore, while modern methods like shotgun metabarcoding provide precise identification, they may not be accessible to all researchers due to their cost and technical requirements. Future research should focus on developing innovative, cost-effective, and reliable methods for the production and quality control of these products. It is therefore paramount for this study to examine the quality measures of herbal medicine.

2.3 Quality and Reliability of Herbal Medicine Products

Herbal medicine products (HMPs) have been used for centuries for disease prevention, treatment, and management as well as for general healthcare and maintenance.

However, the quality and reliability of these products are of paramount importance to ensure their efficacy and safety. This literature review critically analyses four recent studies that focus on the quality control and reliability of HMPs.

Chen et al. [29] highlighted the importance of modern techniques in the quality control of herbs. They argue that traditional analysis methods are time-consuming and laborious, necessitating the need for faster, cheaper, and more environment-friendly techniques. Infrared (IR) and Raman spectroscopy techniques are proposed as potential solutions for quality control and safety inspection. These techniques offer the advantage of being nondestructive, rapid, and capable of providing detailed information about the chemical composition of herbs. However, the practical application of these techniques on a large scale remains a challenge due to the complexity of herbal products and the need for specialized equipment and expertise.

Furthermore, in the traditional Chinese medicine context, Xiao et al. [30] provide a comprehensive review of the traditional uses, phytochemistry, and pharmacology of *Euodiae Fructus* in their study. The authors emphasize the importance of quality control in ensuring the safety and efficacy of this traditional Chinese medicine. They highlight the various pharmacological activities of *Euodiae Fructus*, such as its anti-inflammatory, antibacterial, and anticancer properties. However, the study does not provide a detailed methodology for quality control, which could limit its practical application. This omission underscores the need for more research into practical, effective quality control methods for traditional Chinese medicine.

Building on the theme of quality control, present a compelling study wherein they highlighted the need for reliable detection methods for aflatoxin, a potent carcinogen produced by certain molds. They underscore the importance of quality control in ensuring the safety of herbal products. The study provides a comprehensive review of recent developments in screening assays for aflatoxin qualification or quantitation, including lateral flow immunoassays, enzyme-linked immunosorbent assays, aptamer-based lateral flow assays, and cytometric bead arrays. However, the global occurrence of aflatoxin contamination and the complexity of testing for it in herbal products present significant challenges. This study underscores the need for more research into effective, practical methods for detecting aflatoxin in herbal products.

Finally, Noviana et al. [31] contribute to the discussion on standardization and quality control of herbal medicines in their study. The authors argue that fingerprint analysis allows for the evaluation of the whole chemical profile of herbal drugs, thereby ensuring their quality and reliability. They present a comprehensive review of various fingerprinting techniques and their application in the standardization and quality control of herbal medicines. However, the application of these techniques requires advanced analytical tools and expertise, which may not be readily available in all settings. This limitation underscores the need for more research into cost-effective, user-friendly techniques for the quality control of herbal products.

A critical analysis of the above literature reveals that quality and reliability are indeed critical aspects of HMPs. The reviewed studies highlight the importance of modern analytical techniques in ensuring the quality and safety of these products. However, the practical application of these techniques on a large scale remains a challenge due to the complexity of herbal products and the need for specialized equipment, expertise, and increased cost. This further justifies the need for understanding consumer perception and demand for sustainable herbal medicine products and market, as this will provide an understanding of market demand and dynamics and can promote the need for future research focusing on developing cost-effective and user-friendly techniques for quality control of herbal products. Despite the limitations of the current studies, they provide valuable insights into the current state of quality control and reliability in the field of herbal medicine products and pave the way for future research in this area.

2.4 Global Demand for Herbal Medicine

The escalating global demand for herbal medicine products (HMPs) is a phenomenon that has been propelled by a confluence of factors. These include heightened awareness of the potential benefits of herbal medicine, the prevalence of chronic diseases, and the pursuit of natural alternatives to conventional medicine. This trend is particularly pronounced in the traditional medicinal systems of Asia and India, which are at the vanguard of this surge in demand.

In the study by Li et al. (2021), the authors employed a systematic review methodology to explore the potential of traditional Asian herbal medicine in the treatment and prevention of COVID-19. They discovered that several plant bioactive compounds exhibited potent antiviral activity against SARS-CoV-2, suggesting a promising avenue for future research. This study underscores the potential of herbal medicine in addressing global health crises, such as the COVID-19 pandemic. The authors argue that the antiviral properties of certain plant bioactive compounds could be harnessed to develop effective treatments for COVID-19. This revelation is particularly significant in the current global health landscape, where the need for effective treatments for emerging diseases is more pressing than ever.

In a similar vein, the study by Kumar et al. (2020) illuminates the diverse health practices of traditional Indian medicine, including the use of herbal medicine for the treatment of diabetes. The authors conducted an extensive review of the literature and found that herbal medicines, particularly those used in Ayurveda, have shown promising results in managing diabetes and its complications. This study provides evidence of the effectiveness of herbal medicine in managing chronic diseases, such as diabetes. The authors argue that the use of herbal medicine in traditional Indian medicinal systems could be leveraged to meet the growing global demand for natural and effective treatments for chronic diseases. This is a significant finding, considering the global burden of chronic diseases and the need for effective management strategies.

However, the landscape of herbal medicine is not static, with technology playing a pivotal role in its transformation. The study by Banerjee and Mitra (2011) discusses the increasing demand for herbal medicine, attributing this to an herbal "renaissance." The authors found that scientific research and modern technology have played a crucial role in the industrial growth of herbal medicine. They highlighted the importance of technological advancements in improving the quality, safety, and efficacy of herbal medicines. This study underscores the role of technology in meeting the growing global demand for high-quality herbal medicine. The authors argue that technological advancements, coupled with scientific research, could be harnessed to improve the quality, safety, and efficacy of herbal medicines, thereby meeting the growing global demand for high-quality herbal medicines.

This increasing demand for herbal medicine has led to the expansion of partnerships between farmers and the herbal medicine industry, as discussed in the research by Mulyono Daru [32]. The author found that this partnership was crucial for the development of the economic community, leading to increased income for farmers and improved availability of herbal medicines for consumers. This study underscores the role of partnerships in meeting the growing global demand for herbal medicine. The authors argue that partnerships between farmers and the herbal medicine industry could be leveraged to increase the production of herbal medicines, thereby meeting the growing global demand for these products.

On the other hand, the article by Sollini et al. (2020) discusses the use of neural networks for market segmentation in the herbal medicine industry. The authors found that a fit strategy for each market segment should be formulated and executed to add value to both customers and the market. This study underscores the role of market segmentation in meeting the growing global demand for herbal medicine. The authors argue that market segmentation strategies, formulated and executed using neural networks, could be used to add value to both customers and the market, thereby meeting the growing global demand for herbal medicine. While these developments are promising, they also highlight several challenges. The lack of standardization in these processes can lead to significant variations in the quality and reliability of HMPs. Moreover, while the economic benefits of high-quality and reliable HMPs are evident, the cost implications of achieving these standards can be substantial. This necessitates rigorous quality assurance and validation processes to ensure the safety and efficacy of these products.

In summary, the global demand for herbal medicine is on the rise, and understanding consumer perception toward these products is crucial for the sustainable growth of the herbal medicine market. Despite the challenges, high-quality and reliable HMPs can provide substantial economic benefits by making healthcare more accessible and affordable, thereby justifying the need for further research in this area.

3 Assessment of Consumer Perception and Demand for Sustainable Herbal Medicine Products and Market Using Online Survey Instrument

3.1 Philosophical Framework, Approach, and Design

The philosophy adopted to assess consumer perception and demand for sustainable herbal medicine products and markets using an online survey instrument is pragmatism, which combines the positivist and interpretivist approaches to solve practical problems and improve human conditions as presented in Feilzer (2009). Pragmatism was chosen because it allows for the practical application of knowledge in a specific context (Sauders et al., 2016). The research problem required the investigation of consumer perception and demand for sustainable HMPs, which involved both objective and subjective aspects. The study required a flexible method to obtain answers to the key assessment questions and neither positivism nor interpretivism could successfully bridge this gap.

The assessment approach chosen for this assessment focused on addressing practical problems and generating solutions that can be directly implemented. This approach aligned well with the research objectives, which aimed to explore consumer perception and demand for sustainable herbal medicine products. It allowed the evaluation of a subject with an incomplete set of available data, making it the most suitable approach for a pragmatic philosophical stance (Williamson, 2016).

The applied research adopted a mixed-methods approach that combined the strengths of both qualitative and quantitative research methods to provide a more comprehensive understanding of the research problem. It involved using both inductive and deductive approaches to data collection and analysis, allowing exploration of different aspects of the research question and enhancing the validity and credibility of the findings (Creswell, 2013).

The assessment strategy adopted was that of a mixed-methods approach, using both qualitative and quantitative research methods to collect data (Creswell and Plano, 2017). Surveys were chosen as they were a cost-effective strategy to collect a large amount of data quickly and easily, while also allowing for the standardization of questions and responses, making the data easier to analyze (Nardi, 2016).

The design adopted for this work was a cross-sectional online-based survey, a type of observational study that involves the analysis of data collected from a population, or a representative subset, at a specific point in time. Cross-sectional surveys are particularly suited to this study as they allow for the collection of data on multiple variables simultaneously, providing a comprehensive snapshot of the current state of consumer perceptions and demand for sustainable HMPs [33].

3.2 Data Collection Participants Population and Sample Selection

Data collection was a pivotal aspect as it enabled the quality and reliability of the assessment data obtained (Saunders et al., 2016). In this assessment, a mixed-method approach was employed using both closed and open-ended questionnaires to evaluate consumer perception and demand for sustainable herbal medicine products. The data collection procedure involved distributing the questionnaire to the selected sample. This is done either in person or online, depending on the preferences and accessibility of the participants. Participants are provided with information about the assessment and their rights as participants and are required to provide informed consent before participating. The questionnaire was self-administered, allowing participants to complete it at their own pace and in their own time. Assistance was provided if needed, and confidentiality is maintained throughout the process [33].

The target population for this assessment primarily includes consumers of herbal medicine products. Given the broad nature of this population, a convenience sampling technique is employed. This non-probability sampling technique involves selecting participants based on their availability and willingness to participate in the assessment. While this method may not provide a perfectly representative sample of the entire population, it is practical and efficient for studies where the population is diverse and hard to reach (Etikan et al., 2016).

The sample size is determined using the Krejcie and Morgan table [34] for determining sample size, which provides a recommended sample size based on the population size. This ensures that the sample is large enough to provide reliable results but not so large as to be impractical or unnecessarily costly [34].

3.2.1 Quantitative Data Collection

The primary method of quantitative data collection in this study was using closed-ended questionnaires. The questionnaires were structured with a series of statements, and participants were asked to indicate their level of agreement or disagreement on a Likert scale. This allowed for the collection of quantitative data that could be easily analyzed using statistical methods.

The use of closed-ended questionnaires allowed for the collection of a large amount of data in a relatively short amount of time, making it a cost-effective and efficient method of data collection. However, one potential limitation of this method is the possibility of response bias, where participants may not answer truthfully or may not fully understand the questions being asked, leading to inaccurate or incomplete data.

3.2.2 Qualitative Data Collection

In addition to closed-ended questionnaires, open-ended questionnaires were used to collect qualitative data. The open-ended questions were designed to allow participants to express their views and experiences in their own words. This provided rich, detailed data that could provide insights into the reasons behind the attitudes and perceptions identified in the closed-ended questions. The use of open-ended questionnaires allowed for the collection of qualitative data that could provide a deeper understanding of the research problem. However, one potential limitation of this method is that it can be time-consuming to analyze due to the need to code and categorize the responses.

3.2.3 Data Collection Procedure

The data collection procedure involved distributing the questionnaire to the selected sample. This was done either in person or online, depending on the preferences and accessibility of the participants. Participants were provided with information about the study and their rights as participants and were required to provide informed consent before participating. The questionnaire was self-administered, allowing participants to complete it at their own pace and in their own time. Assistance was provided if needed, and confidentiality was maintained throughout the process.

3.2.4 Data Analysis

The data analysis for this study involves both quantitative and qualitative methods. Quantitative data from the customer surveys, collected via Google Forms, was analyzed using Microsoft Excel. This statistical tool facilitated the computation of descriptive statistics such as frequencies, means, and standard deviations [35]. Utilizing Microsoft Excel for data analysis enhanced the accuracy of the results and minimized the potential for human error during the analysis process.

In addition to the quantitative data, qualitative data were analyzed using a thematic coding approach, which involved identifying and studying recurring patterns in the data (Braun & Clarke, 2006). This six-step process, outlined below, allowed for a comprehensive understanding of the data:

1. **Familiarization with the Data**: The initial step involved thoroughly reading the data multiple times to gain a comprehensive understanding of the information provided by the participants. This step also involved identifying initial patterns and themes within the data.
2. **Generation of Initial Codes**: After understanding the data, areas of interest were identified, and initial codes were generated. These codes represented key aspects of the data that were relevant to the research question.
3. **Search for Themes**: The next step involved identifying common themes across the data and linking them to the relevant codes.
4. **Review of Themes**: The identified themes were then reviewed to ensure they were comprehensive and relevant to the research objectives.
5. **Definition and Naming of Themes**: Each theme was then defined and named in a way that accurately represented the data and was relevant to the research objectives.
6. **Production of the Report**: Finally, a detailed report was produced that described how the themes related to the research objectives. This report was used to draw conclusions and make recommendations based on the findings of the study.

3.3 Validity and Reliability of Data

Ensuring validity and reliability in research is crucial for producing accurate, credible, and trustworthy results. Validity refers to the extent to which a study measures what it intends to measure, while reliability refers to the consistency and stability of the results over time (Saunders et al., 2016). In this assessment, validity was ensured by carefully designing the questionnaires to accurately measure consumer perception and demand for sustainable HMPs. The reliability of the data was ensured by using a consistent method of data collection and analysis.

3.4 Ethical Consideration

Ethical considerations are fundamental principles that guide the conduct of research, ensuring it is carried out responsibly and with integrity [36]. When conducting research involving human participants, it is crucial to consider these ethical principles. These principles safeguard the rights and welfare of the participants and ensure that they are not subjected to harm. Adherence to ethical principles also upholds the integrity of the research and fosters trust in the research findings. This study adhered to the following ethical considerations:

1. **Voluntary Participation**: The principle of voluntary participation was strictly observed throughout this research. Participants were invited to participate in the study and were informed that their involvement was entirely voluntary. They were also made aware that they could withdraw from the study at any time without any repercussions, aligning with the recommendations of Bryman and Bell [36].
2. **Informed Consent**: Consistent with the guidelines outlined by Mbuagbaw et al. (2013), informed consent was obtained from all participants. Before their participation, participants were provided with comprehensive information about the study's purpose, nature, potential risks, and benefits. They were then asked to sign an informed consent form, indicating their voluntary agreement to participate in the study.
3. **Confidentiality and Anonymity**: The confidentiality and anonymity of participants were maintained throughout the study. Personal information collected during the study was securely stored and kept confidential. Participants were assured that their responses would remain anonymous and that their participation would not result in any adverse consequences. This approach aligns with the recommendations of Lwin et al. (2017).
4. **Fair Treatment**: Participants were treated fairly and respectfully throughout the study. The selection of participants was based on established criteria, ensuring there was no discrimination or bias in the data analysis. Participants were not exposed to any harm or discomfort during the assessment, and they were free to withdraw from the assessment without penalty, as emphasized by Ahn et al. (2018).
5. **Data Protection**: The protection of data was a key ethical consideration in this study. All data collected during the assessment was securely stored and kept confidential, accessible only to authorized personnel. The data was stored on a password-protected computer and was used solely for this assessment. This approach aligns with the recommendations of Saunders et al. (2016).

3.5 Survey Respondents

There was a total of 120 respondents, and the response rate of 96% ($n = 115$) was deemed adequate and representative of the sample (Table 1).

3.6 Objective One: To Investigate the Level of Consumer Awareness and Knowledge About Sustainable Herbal Medicine Products

To achieve the first objective, respondents were asked three questions as presented in Sects. 3.6.1, 3.6.2, and 3.6.3.

3.6.1 Awareness of Herbal Medicine

A significant majority of respondents, 63.2% (n = 72), reported that they heard about herbal medicine through family and friends (Fig. 1). The finding supports the report of Abdelmola et al. [37] that the views of family and friends influence patients' views of HMP. In turn, this will contribute toward traditional knowledge and practices surrounding herbal medicine as posited by Vujicic and Cohall [38] wherein they stated that herbal medicine knowledge is mostly acquired from family members and loved ones. The trend observed in the present study indicates a strong influence of personal networks in the dissemination of information about herbal medicine. The second most common source of information was recommendations, with 20.2% of respondents stating that someone recommended herbal medicine to them. This suggests that word-of-mouth plays a crucial role in spreading awareness about herbal medicine. Public advertisements were the third most common source, with 11.4% of respondents learning about herbal medicine this way. This shows that despite the prevalence of modern advertising methods, they are less influential in this context compared to personal networks and recommendations. Finally, a small portion of respondents, 5.3%, mentioned other sources of information. This category could include a variety of sources such as online research, health professionals, books, etc. Therefore, personal networks and recommendations appear to be the most effective

Table 1 Respondents of the online survey on consumer perception and demand for sustainable herbal medicine products and market

Respondents	Number	Percentage
Total targeted customers	120	100
Total questionnaires filled by customers	115	96

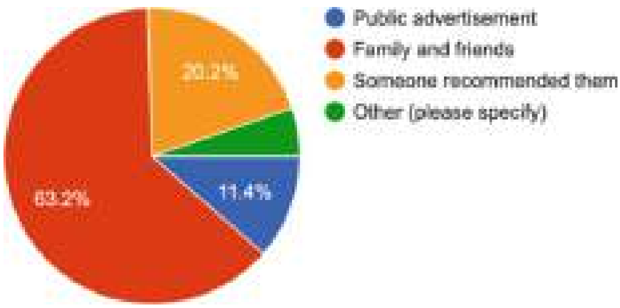

Fig. 1 Respondent's awareness of herbal medicine

channels for spreading awareness about herbal medicine, while public advertisements play a lesser role. Further research could explore the “others” category in more detail to identify any other significant sources of information.

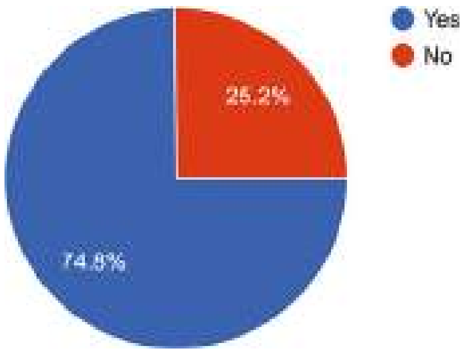
In support of the findings reported by Ahmed et al. (2022) and Hasen et al. (2021), the results of the current survey indicate a high level of awareness about herbal medicine among respondents. A significant majority (63.2%) reported learning about herbal medicine through family and friends, while 20.2% heard about it through recommendations. This suggests that information about herbal medicine is widely disseminated through personal networks.

3.6.2 Usage of Herbal Medicine

Ekor [39] suggests around 80% of the world’s population relies on HMPs and practices for their healthcare. In the current survey, the respondents were probed about their usage of herbal medicine with the question as presented in Fig. 2. A significant majority of respondents (74.8%) reported that either they or their loved ones have used herbal medicine. This indicates a high level of engagement with herbal medicine within the respondent’s personal or familial context. According to Niemeyer et al. [40], engagement with herbal medicine for healthcare is a nonlinear process that has both individual and global effects beyond symptom reduction. The current survey also revealed that 25.2% of respondents stated that neither they nor their loved ones have used herbal medicine. This group represents a quarter of the respondents, suggesting that while herbal medicine usage is prevalent, it is not universal among the survey participants. It therefore means most respondents or their loved ones have experience with using herbal medicine, demonstrating its widespread usage. However, a significant minority have not engaged with herbal medicine, indicating potential areas for growth and outreach.

The high level of engagement (74.8%) with herbal medicines reporting here will likely have a correlative effect on healthcare as well as in the use and conservation of plant resources [41–45]. In essence, a greater number of people and their loved ones use to have personal or familial experience with herbal medicine, which could

Fig. 2 Usage of herbal medicine among respondents



contribute to their knowledge about these products as well as a desire for an improvement in the sector through incorporating sustainability.

3.6.3 Purchase or Recommend the Use of Herbal Medicine

The respondents were further probed on their use of herbal medicine and their responses are presented in Fig. 3. The results for the future intent to purchase or recommend herbal medicine indicate a significant majority of respondents (80.9%), indicating a positive response. This suggests a strong inclination toward the use of herbal medicine, either for personal use or as a recommendation to others. The use is mostly for the promotion of health as well as a therapy for chronic health issues as opposed to life-threatening conditions, especially for conditions that conventional medicine has proven ineffective to address [46, 47]. However, it is important to note that 19.1% of respondents stated that they would not buy or recommend herbal medicine. This group represents nearly one-fifth of the respondents, indicating a degree of resistance or hesitation toward herbal medicine. Therefore, while most respondents expressed a willingness to buy or recommend herbal medicine, a significant minority expressed the opposite. This suggests that while herbal medicine has a strong acceptance, there is still a segment of the population that remains unconvinced, indicating potential areas for education and outreach. In this regard, Soltani et al. (2022) noted that interest and desire to use HMPs are linked to their availability, safety perception, and lack of healthcare options.

Therefore, the future intent to purchase or recommend herbal medicine is also high among respondents, with 80.9% (n = 93) indicating a positive response. This suggests a strong inclination toward the use of herbal medicine and could reflect a level of knowledge and trust in these products.

3.7 Objective Two: To Examine the Factors Influencing Consumer Demand for Sustainable Herbal Medicine Products

To achieve objective two, respondents were asked three questions as outlined in Sects. 3.7.1, 3.7.2, and 3.7.3. Factors considered in this objective included efficacy,

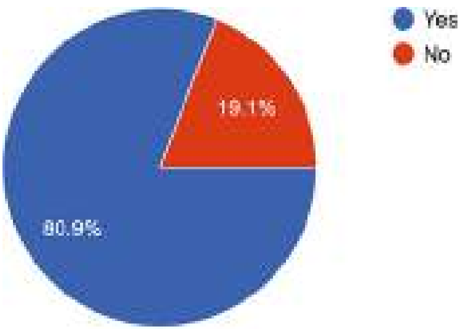


Fig. 3 The likelihood that respondents will buy or use herbal medicine

availability, safety, price, packaging, and overall availability of these products and findings may be summarized as follows.

1. **Efficacy**: A significant 72.5% of respondents indicated that the perceived effectiveness of herbal medicines was a primary factor influencing their purchasing decisions. This suggests that consumers place a high value on the health benefits of these products.
2. **Availability**: Approximately 28.4% of respondents purchase herbal medicines because they are easy to find, indicating the importance of widespread accessibility and distribution. Additionally, 32.5% of respondents stated that availability greatly influences their use of herbal medicine products, further emphasizing the role of accessibility in consumer demand.
3. **Safety**: Around 29.4% of respondents purchase herbal medicines due to their belief in their safety, reflecting a level of trust in these products and possibly a perception of herbal medicines being a safer alternative to conventional medicines.
4. **Price**: Only 26.5% of respondents base their purchasing decisions on price, suggesting a willingness to pay a premium for products perceived as effective and safe.
5. **Packaging**: Packaging significantly influences 37.2% (n = 42) of respondents, while 26.5% (n = 30) state it sometimes does. This indicates that packaging can play a role in shaping consumer perceptions and potentially their purchasing decisions.

3.7.1 What Makes You Buy or Use Herbal Medicine

Respondents were asked what makes them buy and use herbal medicine and their responses are presented in Fig. 4. The results indicate factors influencing their decision to purchase and use herbal medicines and provide insights into consumer behavior in this market. Efficacy emerged as the most significant factor, with 72.5% of respondents indicating that they purchase herbal medicines due to their perceived effectiveness. This suggests a high value placed on the health benefits of these

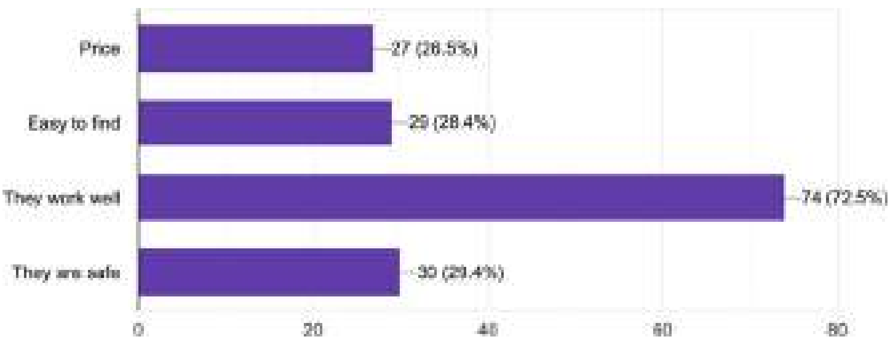

Fig. 4 Reason for buying or using herbal medicines

products by consumers. Nonetheless, Wachtel-Galor and Benzie [47] opined that research is needed to ensure the quality, molecular effects, safety, and clinical efficacy of HMPs to the perceived public view of the efficacy of the products. In the same, Bent [48] opined that HMPs will not become an important alternative to modern medical therapies unless important regulatory changes are made. The survey also revealed that the availability of herbal products also influences purchasing decisions. Approximately 28.4% of respondents purchase herbal medicines because they are easy to find, indicating the importance of widespread accessibility and distribution. Safety is another key consideration, with 29.4% of respondents purchasing herbal medicines due to their belief in their safety. This reflects a level of trust in these products and could be interpreted as a perception of herbal medicines being a safer alternative to conventional medicines. Interestingly, price appears to be less significant in the decision-making process. Only 26.5% of respondents base their purchasing decisions on price, suggesting a willingness to pay a premium for products perceived as effective and safe.

This study, therefore, noted the perceived efficacy, availability, and safety of herbal medicines are key drivers of purchase decisions. While price is a consideration, it is less influential than the other factors. These insights can inform marketing strategies in this sector.

3.7.2 Impact of Packaging on the Perception of Herbal Medicine

Furthermore, respondents were asked about the impact of packaging on the perception of herbal medicine and their response is response in Fig. 5. Recently, Aziato and Odai [49] and Vaezi et al. [50] reported that bad packaging alongside inadequate or unclear dosage information and labelling are some major barriers militating the use of herbal medicines. Here, respondents were queried about the impact of packaging on their perception of herbal medicine products as shown in Fig. 5. The findings reveal that packaging plays a varying degree of role in shaping consumer perceptions. A significant proportion of respondents, 37.2%, indicated that packaging greatly influences their perception of herbal medicine products. This suggests that for a considerable segment of consumers, packaging is a critical factor in shaping their views and potentially their purchasing decisions. Approximately 26.5% of

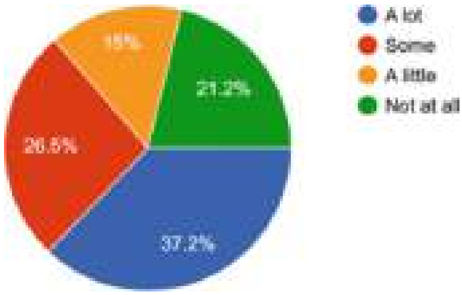

Fig. 5 Impact of herbal medicine packaging on consumer perception

respondents stated that packaging sometimes affects their perception. This indicates that while packaging may not be the primary factor influencing their views, it does have an impact under certain circumstances or for specific products. A smaller percentage, 15%, reported that packaging has a minimal effect on their perception of herbal medicine products. For these consumers, other factors may be more influential in shaping their views. Finally, 21% of respondents stated that packaging does not affect their perception at all. This group appears to be indifferent to packaging and likely bases their perceptions and decisions on other factors. The observed patterns may be linked to the views of Zhou et al. [51] that packaging and labelling help in distinguishing adulterated from unadulterated HMPs as well as quality control and positive consumer perception. In summary, while packaging significantly influences a substantial segment of consumers, its impact varies, with a noteworthy percentage of consumers being unaffected by it. These insights can guide businesses in the herbal medicine sector in their packaging and marketing strategies.

3.7.3 Availability of Herbal Medicine and Consumer Perception

Respondents were asked about the impact of availability on their use of herbal medicine products and the responses as presented in Fig. 6. The findings reveal that availability plays a varying degree of role in influencing consumers' usage of these products. A significant proportion of respondents, 32.5%, indicated that availability greatly influences their use of herbal medicine products. This suggests that for a considerable segment of consumers, the ease of access or procurement of these products is a critical factor in their usage decisions. It is in line with the findings of Mbali et al. [52] that the availability and accessibility HMPs contribute to their use and acceptance, especially in low-resource communities. Approximately 25.4% of respondents stated that availability sometimes affects their use of herbal medicine products. This indicates that while availability may not be the primary factor influencing their usage, it does have an impact under certain circumstances or for specific products. A smaller percentage, 16.7%, reported that availability has a minimal effect on their use of herbal medicine products. For these consumers, other factors may be more influential in shaping their usage

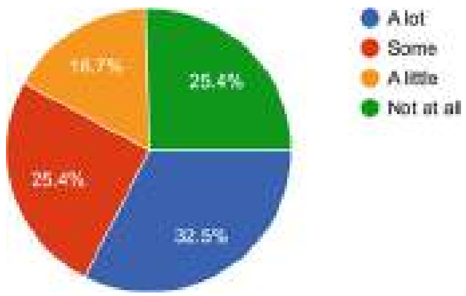

Fig. 6 Impact of herbal medicine availability and consumer perception

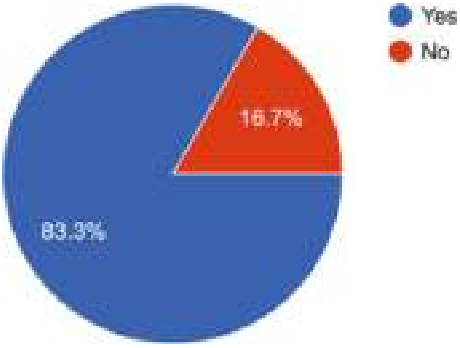
decisions. Finally, 25.4% of respondents stated that availability does not affect their use of herbal medicine products at all. This group appears to be indifferent to the availability of products and likely bases their usage decisions on other factors. In summary, while availability significantly influences a substantial segment of consumers in their usage of herbal medicine products, its impact varies, with a noteworthy percentage of consumers being unaffected by it. These insights can guide businesses in the herbal medicine sector in their distribution and marketing strategies.

3.8 Objective Three: To Assess Consumers' Perception of the Efficacy and Safety of Sustainable Herbal Medicine Products

To achieve this research's third objective, the study examined the following questions outlined in Sects. 3.8.1, 3.8.2, 3.8.3, 3.8.4, and 3.8.5. The third objective was set to assess the perception of consumers toward the efficacy and safety of sustainable herbal medicine products. The study revealed the following perceptions:

1. **Perception of Efficacy**: In the study, a substantial majority perceived herbal medicines as being equally or more effective than conventional medicines. Specifically, 45.1% believed herbal medicines were "a bit better," and 22.1% considered them "much better." In contrast, 18.6% viewed herbal and conventional medicines as equally effective, while a minor yet significant portion viewed herbal medicines as less effective. This indicates a prevalent belief in the high efficacy of herbal medicines, albeit with some reservations.
2. **Perception of Safety**: In assessing the perceived safety of herbal medicines compared to conventional ones, most respondents deemed herbal medicines to be safer. Approximately 27.2% agreed that herbal medicines are "a lot safer," and another 25.4% considered them "a bit safer." However, a noteworthy proportion of respondents expressed safety concerns or perceived equal safety with conventional medicines, highlighting a need for further safety-focused consumer education and possibly enhanced safety procedures for herbal medicines.
3. **Perception of Sustainability and Environmental Impact**: The survey results suggested that most respondents view herbal medicines as environmentally friendly. Specifically, 46.5% believed they are "a lot" environmentally friendly, and 36.8% believed they are "somewhat" environmentally friendly. Nevertheless, a small yet significant proportion of respondents did not share this view, indicating a potential area for increased communication about the environmental sustainability of herbal medicine production.
4. **Perception of General Health Impact**: When asked about their belief in the overall positive health impact of herbal medicines, 80% of the respondents agreed to some degree, indicating a generally favorable perception. However, a smaller yet significant portion expressed reservations or disbelief, demonstrating an area for potential improvement in product communication and education.

Fig. 7 Desire to see an increase in herbal medicine products in stores



3.8.1 Would You Prefer to See an Increase in the Availability of Herbal Medicine Within Stores?

The response to this question is presented in Fig. 7. This quantitative inquiry aimed to ascertain whether a significant demand exists and to further identify potential market dynamics. Of the respondents, a substantial 83.3% affirmed their preference for the heightened presence of herbal medicine products in the market. This denotes a clear majority favoring the increased accessibility of such merchandise, potentially elucidating a promising avenue for businesses considering the proliferation of their herbal medicine offerings. In contrast, a minority contingent of 16.7% ($n = 19$) expressed a lack of interest in seeing an augmentation in the availability of herbal medicines within retail venues. This dissenting perspective is essential, as it embodies a subset of the market that might not be amenable to the enhanced prevalence of these products. In summation, the data collected presents a convincing inclination toward the increased availability of herbal medicines among most participants, providing valuable insight for potential market expansion strategies. Nevertheless, the dissenting minority underscores the significance of market diversification and hints at the necessity for a more comprehensive understanding of varied consumer preferences.

3.8.2 Do You Believe That Herbal Medicines Work Better, Worse, or the Same as Conventional Medicines?

Respondents were asked about the efficacy of herbal medicine in comparison with orthodox medicine with the question presented in Fig. 8. Most respondents indicated a belief in the superior or equal effectiveness of herbal medicines relative to conventional ones. Precisely, 45.1% of respondents expressed that herbal medicines perform “a bit better,” while 22.1% suggested they work “much better.” There also exists a significant portion of the market, 18.6%, that perceives herbal and conventional medicines to have equivalent effectiveness. This data identifies a group that does not distinguish between the two types of medicine in terms of their therapeutic impact. Conversely, a minority of respondents held a less favorable view of herbal medicines. About 8% indicated that herbal medicines perform “a bit worse,” and a

Fig. 8 Respondents believe herbal medicines work better than regular medicines

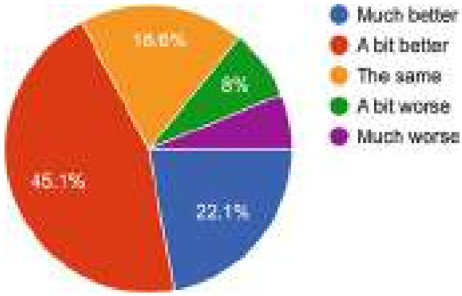


Fig. 9 Respondent's perception of the benefits of herbal medicines

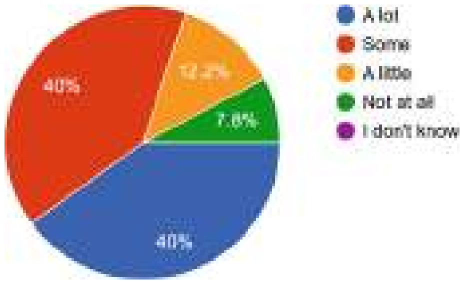
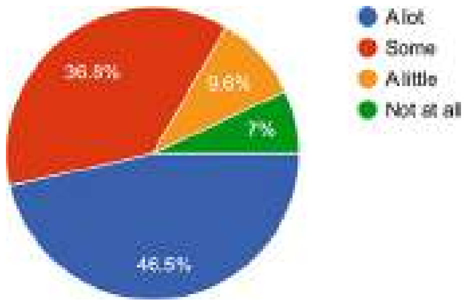


marginal 6.2% believed they work "much worse" than conventional medicines. In summary, the findings of this survey reveal that most participants perceive herbal medicines as being equally or more effective than their conventional counterparts. This indicates a promising potential for expansion within the herbal medicine market. However, attention must be given to the minority perception of lesser effectiveness, which underscores a need for further consumer education or potential product enhancement strategies.

3.8.3 Do You Believe That Herbal Medicines Are Good (Safe and Work Well) for Healthcare and Management?

Furthermore, respondents were asked "Do you believe that herbal medicines are good (safe and work well) for health care and management?" as shown in Fig. 9. A significant proportion of the respondents, constituting 40%, firmly agreed that herbal medicines are significantly good for healthcare and management. Another equally substantial group, again 40%, agreed to some extent, demonstrating a moderate level of confidence in the effectiveness and safety of herbal medicines. However, a noticeable percentage of participants held more reservations. Precisely, 12.2% of respondents believed only "a little" in the effectiveness and safety of herbal medicines for healthcare and management. Lastly, a minority group of respondents, 7.8%, disagreed entirely with the notion that herbal medicines are good for healthcare and management, indicating no belief in the safety or effectiveness of these products. Therefore, the data reveal a substantial belief in the safety and

Fig. 10 Perception of the environmental benefits of herbal medicines



effectiveness of herbal medicines among most surveyed individuals, providing a promising outlook for the herbal medicine market. However, a small yet significant proportion of respondents hold reservations or outright disbelieve the value of herbal medicines in healthcare and management. These perceptions are crucial to acknowledge for future market strategies, particularly those involving consumer education and communication.

3.8.4 Do You Think Herbal Medicines Are Environmentally Friendly?

In addition, respondents were asked "Do you think herbal medicines are environmentally friendly?" and the result is presented in Fig. 10. A significant majority of the respondents hold a strong belief in the environmental friendliness of herbal medicines. Specifically, 46.5% indicated that herbal medicines are "a lot" environmentally friendly. Furthermore, a substantial 36.8% hold the belief to "some" extent, showing a moderate level of agreement with the environmental friendliness of these products. Nevertheless, there is a minority of respondents who express less certainty. About 9.6% believe that herbal medicines are "a little" environmentally friendly, indicating a lower level of agreement. Moreover, a smaller group, 7%, disagreed entirely with the proposition that herbal medicines are environmentally friendly. In summary, the findings reveal that a substantial majority of respondents perceive herbal medicines as environmentally friendly to varying degrees. This indicates a promising alignment with growing global trends toward environmentally friendly products. However, there remains a smaller segment of respondents who either express reservations or disagree entirely, suggesting the need for further education and communication about the environmental impact of herbal medicines.

3.8.5 Do You Think Herbal Medicines Are Safer Than Regular Medicine?

Furthermore, respondents were asked: "Do you think herbal medicines are safer than regular medicine?" as shown in Fig. 11. A clear majority of the respondents demonstrated a perception of herbal medicines as being safer than conventional medicines. Specifically, 27.2% of respondents agreed that herbal medicines are "a lot safer," and another 25.4% considered them "a bit safer." However, a significant proportion of respondents, 21.9%, believed that herbal medicines are "a bit less safe"

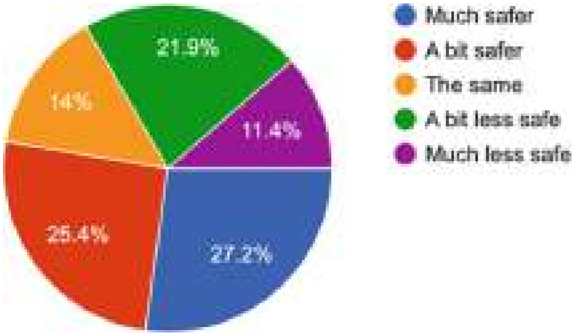


Fig. 11 Comparative safety perception of herbal versus regular medicines

than conventional medicines, indicating a more skeptical view. Additionally, 14% of respondents perceived the safety of herbal and conventional medicines as being the same, suggesting neutrality regarding the relative safety of these two categories of medicines. Lastly, a minority of respondents, 11.4%, believed that herbal medicines are "much less safe" than conventional medicines. In summary, the data reveals a notable majority of respondents perceive herbal medicines as safer than conventional medicines, which could be promising for market trends. However, a significant minority expressed safety concerns or held a perception of equal safety, highlighting the need for further consumer education and potential investigation into safety procedures for herbal medicines.

3.9 Objective Four: To Identify the Barriers and Challenges Consumers Face in Accessing Sustainable Herbal Medicine Products

To access the barriers and challenges consumers face in accessing sustainable medicine. This aspect of the assessment examined the perception of consumers regarding the regulation of herbal medicine. The study set to identify the barriers and challenges consumers face in accessing sustainable herbal medicine products. The survey results provide valuable insights into the challenges and barriers that consumers face when accessing herbal medicine products. They include:

1. **Regulation Perception**: A significant majority of respondents (86.7%) do not believe that herbal medicine is well-regulated. This perception could deter consumers from accessing these products due to concerns about safety, efficacy, and quality control.
2. **Information Gap**: The most common challenge faced when trying to find herbal medicine was a lack of sufficient information, as reported by 65.2% of respondents. This information gap could be related to understanding what herbal medicine products are available, how to use them, where to find them, and their benefits and potential side effects.

3. **Availability**: The second most common challenge was the difficulty in finding herbal medicine, as reported by 45.7% of respondents. This could be due to limited availability in local stores, lack of online options, or geographical constraints.
4. **Cost**: Although only a small proportion of respondents (3.3%) identified cost as a barrier, for those individuals, the price of herbal medicine products could be prohibitive.
5. **Frequency of Difficulty**: When asked about the frequency of difficulty in finding herbal medicine, 48.2% of respondents reported sometimes having trouble, and 10.7% reported often having trouble. This indicates that for a significant proportion of respondents, accessing herbal medicine is not always straightforward.

3.9.1 Do You Think Herbal Medicine Is Well-Regulated?

Response to the current regulation of herbal medicine by respondents is presented in Fig. 12. Most respondents, 86.7%, expressed the belief that herbal medicine is not well-regulated. This indicates a significant concern about the oversight and standards applied to herbal medicine in the current system. On the other hand, a much smaller proportion of respondents, 13.3%, believe that herbal medicine is well-regulated. This group represents a minority view that the existing regulations are sufficient. These results highlight a clear call for increased scrutiny and potentially more stringent regulation in the field of herbal medicine. Further research could explore the specific areas where respondents feel regulation is lacking and propose targeted solutions to address these concerns.

3.9.2 Have You Ever Had Trouble Finding Herbal Medicine?

Respondents were asked about their experiences with finding herbal medicine and their responses are presented in Fig. 13. The responses indicate a mixed experience among the respondents. A significant proportion, 48.2%, reported that they sometimes encounter difficulties when trying to find herbal medicine. This suggests that while they do not consistently struggle to find these products, there are instances where it becomes a challenge. A smaller group, 10.7%, reported often having trouble

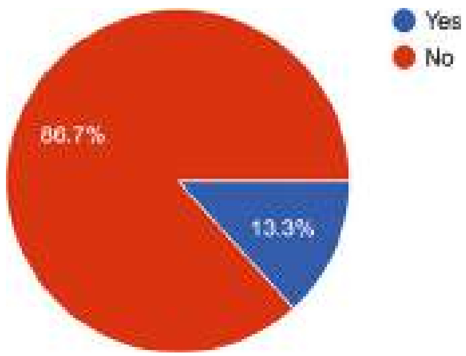

Fig. 12 Respondents believe herbal medicine is not well-regulated

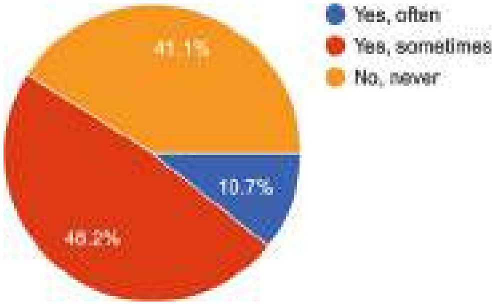

Fig. 13 Most respondents reported having had challenges with finding herbal medicine

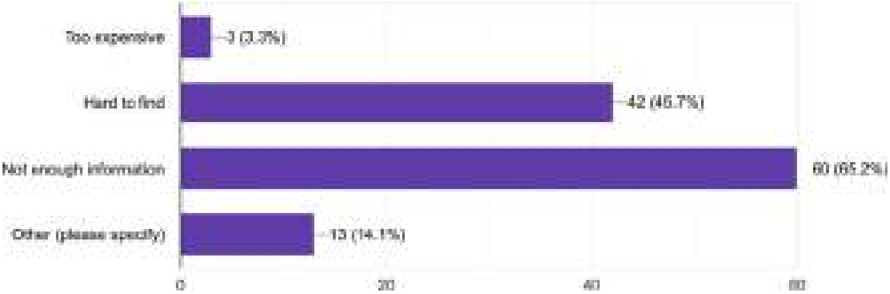

Fig. 14 Challenges associated with finding herbal medicines

finding herbal medicine. This indicates a more consistent struggle, suggesting that for these individuals, the availability or accessibility of herbal medicine is a recurring issue. On the other hand, 41.1% of respondents reported that they do not have trouble finding herbal medicine. This suggests that a substantial proportion of the surveyed population does not encounter significant barriers when seeking out these products. These findings highlight the variability in experiences when it comes to finding herbal medicine. They suggest the need for further investigation into the factors that contribute to these difficulties, particularly for those who often struggle to find these products. This could include factors such as geographical location, availability in local stores, or online access.

3.9.3 If You Had Trouble Finding Herbal Medicine, What Was the Problem?

Respondents were asked to identify the challenges they faced when trying to find herbal medicine and their responses are presented in Fig. 14. The most common issue, reported by 65.2% of respondents, was a lack of sufficient information. This suggests that there is a significant knowledge gap when it comes to understanding, locating, and using herbal medicine. This could be due to a lack of accessible, reliable, and comprehensive resources about herbal medicine. The second most common problem, reported by 45.7% of respondents, was that herbal medicine was hard to find. This could indicate issues with the availability or distribution of herbal medicine in certain areas or markets. A smaller proportion of respondents, 14.1%, reported other unspecified problems. Further research could be conducted to identify and understand these miscellaneous challenges. Finally, a very small group of respondents, 3.3%, reported that the cost of herbal medicine was prohibitive. While this was the least common issue, it is still a significant barrier for those individuals affected. These findings suggest that there are several key areas to address to improve access to and understanding of herbal medicine. These include enhancing the availability of information, improving distribution and availability, understanding, and addressing other miscellaneous challenges, and considering cost factors.

3.10 Open-Ended Questions on Consumer Perception of Herbal Medicine

3.10.1 What Do You Associate with Herbal Medicine?

Participants were asked, "What do you associate with herbal medicine? (i.e., when you think of herbal medicine what comes to mind)." The data was analyzed using thematic analysis and generated the following themes with the frequency of respondents as presented in Table 2. This result provides an overview of the themes identified in people's perceptions and associations with herbal medicines, their frequency, the respondents who mentioned each theme, and a brief description of each theme. The concept of "nature and naturalness" is the most frequently mentioned theme, followed by "safety and healthiness," and "concerns about quality and regulation." "Traditional medicine," "efficacy and effectiveness," and "concerns about dosage and prescription" also appear significantly in responses. The themes of "associations with illness and treatment," "taste and use," and "accessibility and affordability" were mentioned less frequently.

3.10.2 What Would You Like to See Improved Regarding Herbal Medicines?

Respondents were asked: "What would you like to see improved regarding herbal medicines?" and their responses are presented in Table 3. The result provides an overview of the themes identified in perceptions of improvement needs in herbal medicines, their frequency, the respondents who mentioned each theme, and a brief description of each theme. "Information and awareness" is the most frequently mentioned theme, followed by "dosage and prescription" and "packaging and labelling." "Regulation and authentication," "research and development," and "safety concerns" also showed up significantly in the responses. Themes of "accessibility and availability," "taste and aesthetics," and "support from government and NGOs" were mentioned less frequently. Some of these themes align with the earlier report of Fienzouli and Gori (2007) about the safety evaluation and verification of the pharmaceutical efficacy mechanisms of herbal medicines. This is also supported by the report of Bent [48] about the standardization of herbal medicine products and practices, increased regulations, and more funding for research into the products and practices.

Table 2 Perception and association with herbal medicines

Theme	Frequency	Description
Nature and naturalness	27	Associations of herbal medicine with natural products, herbs, plant-based substances, and organic qualities
Safety and healthiness	14	Perception of herbal medicines as safe, less harmful, pure, and offering health benefits with fewer side effects compared to synthetic drugs
Concerns about quality and regulation	16	Concerns about poor regulation, quality, preparation hygiene, and possible adulteration. These concerns often link to perceived risks
Traditional medicine	9	Viewing herbal medicine as traditional, local, or complementary to orthodox medicine, often connected with native doctors/herbalists
Efficacy and effectiveness	11	Beliefs about the effectiveness, potency, and immediacy of herbal medicines in treating illnesses
Concerns about dosage and prescription	8	Worries about proper dosage instructions, lack of research-based data on dosage, and possible health risks due to incorrect dosing
Associations with illness and treatment	8	Associations of herbal medicine with treatment of specific conditions, such as pain, fractures, fertility, and childbirth issues
Taste and use	5	Associations with the taste of herbal medicines, often described as bitter, and their use in food and drinks
Accessibility and affordability	2	Perceptions of herbal medicines as more accessible and affordable compared to orthodox medicine

4 Conclusion

While the cross-sectional design adopted for the assessment reported in this chapter enables the provision of a comprehensive snapshot of consumer perceptions and demand at a specific point in time, it does not allow for the examination of changes over time. Moreover, future research could employ a longitudinal design to track changes in perceptions and demand over time. Additionally, while the use of both closed and open-ended questions in the online assessment tool enabled a comprehensive view of consumer perceptions and demands, the responses are still subject to participant interpretation and bias. Future research could employ more objective measures, such as behavioral observations or physiological measures, to complement the self-report data as suggested in Bryman [33]. Nonetheless, this chapter noted that a significant minority expressed a lack of awareness, usage, or intent to purchase/recommend herbal medicine, which suggests that while there is a high level of awareness and engagement with herbal medicine, there is still a segment of the population that may lack knowledge about these products. Nevertheless, there is a high level of consumer awareness and

Table 3 Perception of improvement needs in herbal medicines

Theme	Frequency	Description
Regulation and authentication	11	Calls for better regulation, authentication, and production standards for herbal medicines
Information and awareness	20	A desire for more enlightenment, information, and awareness about herbal medicines, including details about content, usage, and potential risks
Packaging and labelling	16	Need for improvements in packaging, hygiene, and clarity in labelling with ingredients
Dosage and prescription	17	Emphasizing the importance of clear dosage instructions and prescriptions to avoid potential issues such as overdosing
Research and development	13	Calls for increased research on the safety, efficacy, and contraindications of herbal medicines
Accessibility and availability	7	Suggestions for better access to, and visibility of, herbal medicines
Taste and aesthetics	3	A desire for improvements in the taste and presentation of herbal medicines
Safety concerns	12	Expressions of concern regarding the safety of herbal medicines, including possible side effects and growing conditions
Support from the government and NGOs	2	Suggestions for increased governmental and nongovernmental support and involvement in promoting and regulating herbal medicine

knowledge about herbal medicine products even though there is still a segment of the population that may require further education and outreach. Importantly, the perceived efficacy, availability, safety, and packaging of herbal medicines are key drivers of consumer demand. While price is also key a consideration, it is less influential compared to the other factors considered in this assessment. These insights can inform strategies for businesses in the herbal medicine sector, particularly those focusing on sustainable products. Also, the majority of consumer perception of the efficacy and safety of sustainable herbal medicines is largely positive, suggesting promising prospects for this market. However, there exist some concerns related to safety, efficacy, and environmental impact among a minor yet significant proportion of consumers, highlighting the need for effective communication strategies and potential product enhancements. In conclusion, the key barriers to accessing sustainable herbal medicine products appear to be concerns about regulation, a lack of information, issues with availability, and for some, cost. To improve access to these products, efforts could be made to enhance regulatory transparency, provide more comprehensive and accessible information, improve distribution and availability, and consider affordability. Further research could also be conducted to understand the specific “other” challenges faced by some respondents.

Abstract

Indigenous phytochemistry (i.e., the understanding of the chemical constituents of plants by people of a certain locale) is key to the use of plants in herbal medicine. The chemical composition, beneficial interactions, and therapeutic applications of medicinal plants are discussed, and the importance of indigenous knowledge systems and cultural wisdom is emphasized in this chapter. It delves into the cultural ideas and perceptions that contribute to the success of traditional healing practices, as well as the rituals that accompany them. A more holistic and culturally acceptable approach to healthcare can be achieved by learning about the cultural importance of medicinal plants. Ethical considerations and working together with indigenous communities are also highlighted. Thus, as partners in research, they must treat each other with respect and work together to safeguard intellectual property and distribute profits fairly. Moreover, herbal medicine can be more welcoming as well as culturally sensitive if indigenous knowledge is given due respect and indigenous populations are included in the research process since indigenous phytochemistry has the potential to revolutionize our understanding of herbal medicine's healing properties. Researchers can tap into the potential of indigenous knowledge systems by combining cultural understanding, ecological expertise, and cutting-edge science to create effective, culturally grounded herbal treatments that also support long-term health.

1 Introduction

Indigenous phytochemistry (i.e., the understanding of the chemical constituents of plants by people of a certain locale) is a branch of ethnopharmacology, which is the scientific investigation of the pharmacological effects of natural products used by different cultures. Consequently, culture, customary expertise, and the curative properties of medicinal plants are deeply intertwined in the indigenous herbal medicine practiced by indigenous populations for generations [11, 12, 52, 130, 135, 238, 278]. Traditional indigenous practices and beliefs have been continuously passed down through the generations in indigenous communities and make up the bulk of indigenous knowledge systems [92, 132]. The practice of traditional medicine is an integral part of these systems of expertise because it is grounded on cultural understanding and experiential learning about the therapeutic effects of medicinal plants [67, 136].

Research into medicinal plants from an ethnobotanical perspective is crucial to preserve traditional healing practices [81, 82]. Researching the historical and cultural importance of medicinal plants, these studies integrate anthropology, botany, and chemistry [256, 285]. Ethnobotanical research guarantees the preservation of traditional knowledge and validates the value of traditional medicine by recording it using rigorous scientific approaches [266].

Understanding the chemical components and bioactive chemicals present in medicinal plants requires the use of phytochemical analysis [25, 153–157]. Chromatography, mass spectrometry, and nuclear magnetic resonance spectroscopy are just a few examples of modern analytical techniques that can be used to isolate and characterize individual chemicals [171]. The complex blend of active chemicals responsible for the therapeutic benefits of traditional herbal treatments can be uncovered through phytochemical analysis [287, 21]. This research lends credence to the age-old practice of using plants as medicine and may lead to the development of novel therapeutics.

The notion of synergy motivates the use of many plant constituents in complicated formulations common in traditional herbal therapy. The therapeutic efficacy is increased when many drugs interact synergistically [166]. This indicates that traditional formulations that combine several plant ingredients can increase bioavailability and pharmacokinetics. A greater appreciation for herbal medicine's curative potential can be gained by investigating the synergistic interactions seen in traditional formulations.

Traditional herbal medicine relies heavily on cultural knowledge to be effective. Traditional practitioners have extensive expertise with various plant species, medicinal preparations, and dosages [91]. This accumulated knowledge from previous generations guarantees that medicinal herbs are used effectively within their designated cultural frameworks. Therefore, realizing herbal medicine's full therapeutic potential requires appreciating the reciprocal relationship between cultural awareness and native phytochemistry. Phytochemical examination reveals the chemical elements of therapeutic plants, while ethnobotanical investigations chronicle and authenticate indigenous understanding [278].

In summary, this chapter will deal with the chemical composition, beneficial interactions, and therapeutic applications of medicinal plants by indigenous people. The importance of indigenous knowledge systems and cultural wisdom will also be emphasized in this chapter. It will also delve into the cultural ideas and perceptions that contribute to the success of traditional healing practices, as well as the rituals that accompany them. The need for a more holistic and culturally acceptable approach to healthcare by learning about the cultural importance of medicinal plants will also be highlighted. Ethical considerations and collaboration with indigenous communities will also be highlighted as partners in research. Hence, they need to treat each other with respect and work together to safeguard intellectual property and distribute profits fairly.

2 Integrating Cultural Wisdom and Modern Science

Culture and science can be integrated into today's fast-changing environment. The wisdom of cultures is regarded as the total of humankind's collected knowledge, ideals, and practices across time and societies [191]. It is strongly ingrained in global cultures and traditions. On the contrary, the scope of our modern-day science extends to the exhaustive investigation and clarification of the environment via tested theories and methods [101]. Despite their differences, indigenous knowledge and modern cutting-edge research can work together to address complex global concerns and promote comprehensive health [223].

Insights into sustainable practices, ecological responsibility, and the advancement of general healthcare can be gained through cultural wisdom gleaned via indigenous knowledge systems [141]. It includes in-depth knowledge of ecological connections, traditional medical practices, and the links between people and the natural world. Historical environmental knowledge and indigenous practices have supported communities for generations. Thus, incorporating cultural understanding into scientific study will help us to tap into these resources. This synthesis will allow for the protection of historical artifacts while also yielding fresh approaches to pressing problems of the present.

With its focus on empirical data and rigorous techniques, modern science provides systematic ways to make sense of the world. It has helped propel the fields of medicine, technology, and the hard sciences forward by leaps and bounds. Traditional practices can be made more effective and secure by incorporating current scientific approaches with cultural wisdom. Both indigenous physicians and the

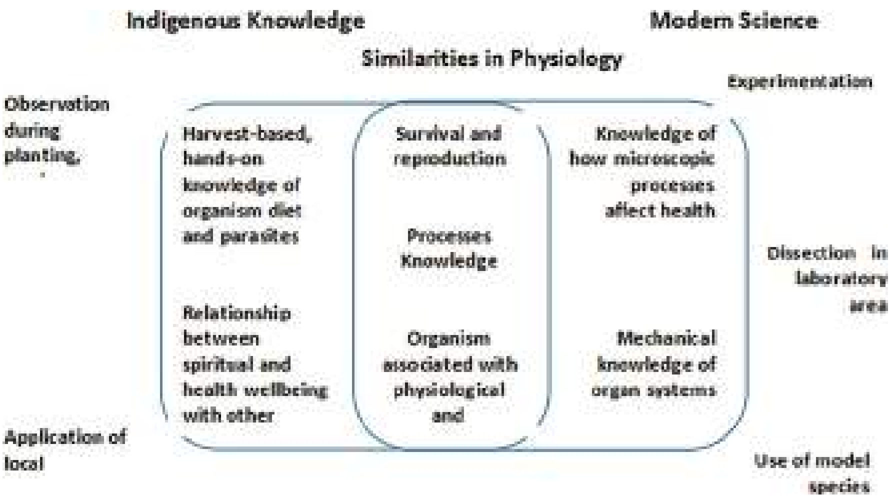

Fig. 1 Indigenous knowledge and modern science share complementary conceptual underpinnings in physiological research

scientific community can gain from cross-cultural partnerships that are made possible by this integration [16].

Moreover, healthcare is one field where traditional knowledge and cutting-edge research both have a place. Holistic methods of wellness and rejuvenation are common in traditional medical treatments because they are grounded in cultural wisdom. Physical attributes, psychological, and spiritual wellness are all seen as interdependent in indigenous healing practices [99]. Thus, care that is both culturally competent and patient-centered can be achieved when conventional medicine is combined with alternative therapies [87].

Also, indigenous knowledge systems are better able to survive and thrive when current scientific information is integrated with cultural knowledge [70, 141]. Sustainability in managing resources, safeguarding biodiversity, and adapting to climate change are all areas in which indigenous cultures excel [27]. Therefore, improved long-term and robust strategies for environmental protection will be possible once we recognize and incorporate this information. Traditional knowledge is preserved and passed on from generation to generation by the incorporation of cultural wisdom into educational and research practices [284] (Fig. 1).

3 Exploration of Bioactive Compounds to Unveil Therapeutic Secrets

The medicinal potential of bioactive chemicals isolated from plants, animals, and microbes has been known for quite some time. The use of these chemicals to create new medications and therapies to treat disease and enhance human health has great potential. According to Newman and Cragg [208], bioactive chemicals are "chemical molecules detected in an environment that exhibit a pharmacological effect on living organisms." Antioxidant, antibacterial, anti-inflammatory, anticancer, and neuroprotective are only some of the activities they display.

Discovering bioactive chemicals entails isolating and studying molecules from nature that may have useful medical properties. Medicinal plants, marine species, and microbial extracts are just some of the natural sources that can be screened for bioactive chemicals [106]. The discovery of new bioactive chemicals has been greatly aided by the development of cutting-edge technologies and methods [142, 262].

The medicinal potential of bioactive chemicals discovered through exploration is illustrated by several examples. The cancer therapy paradigm was shifted with the introduction of paclitaxel, which was isolated from the Pacific yew tree (*Taxus brevifolia*) [212]. Isolated from the *Artemisia annua* plant, artemisinin is useful in treating malaria [172]. In each of these cases, bioactive chemicals are used to their fullest potential, illustrating their promise in resolving serious health issues.

Bioactive chemicals are also excellent starting points for developing new medicines. The efficacy, preference, and pharmacokinetic features of these molecules can be improved through structural alterations and optimization once they have been identified [199]. Researchers can design and produce more effective and safer medications that target specific diseases by tapping into the curative value of bioactive molecules.

Therefore, this chapter focuses on cultural knowledge and indigenous phytochemistry with a special focus on the significance of indigenous knowledge in phytochemistry, the chemical composition of medicinal plants in indigenous knowledge systems, traditional healing practices and their phytochemical foundations, an intertwining of culture and phytochemistry, indigenous wisdom as a treasure trove of phytochemical discoveries and biodiversity conservation, challenges and ethical considerations in indigenous knowledge research, approaches that respects and safeguard indigenous knowledge, synergies between indigenous knowledge and modern phytochemistry in herbal medicine, and the future directions in advancing indigenous phytochemistry research.

4 The Significance of Indigenous Knowledge in Phytochemistry

The science of phytochemistry benefits greatly from indigenous knowledge, which originates in the traditional understandings and practices of indigenous societies. Traditional ecological knowledge and the in-depth insight indigenous peoples hold are invaluable resources for the field of phytochemistry, which studies chemical compounds originating from plants. The section delves into how indigenous knowledge has helped uncover and make use of bioactive substances found in therapeutic plants through the field of phytochemistry.

Native peoples have relied on the natural world for centuries, both as a source of food and medical care [133, 206, 207]. A wide range of plant species, their medicinal properties, and techniques of preparation are all well known to these people [91]. This historical understanding is essential for locating and employing medicinal plants in modern phytochemical studies.

The ability to recognize plants with therapeutic potential is one of the indigenous knowledge's greatest contributions to phytochemistry. Through millennia of observation and testing, indigenous cultures have amassed knowledge about the healing capabilities of numerous plant species [92]. Researchers can benefit greatly from their knowledge of medicinal plants and their indications [117, 120, 260, 261, 312] as it helps them zero in on plants with the most potential for further phytochemical investigation.

4.1 Indigenous Knowledge Systems as a Holistic Approach to Healing

Indigenous knowledge systems provide a comprehensive approach to healing that spans one's physical, psychological, and spiritual health [177]. These systems are profoundly anchored in the cultural legacy and wisdom of Indigenous groups, building on centuries of customary procedures and views.

Indigenous knowledge systems describe health as a situation of harmonious integration between people, groups, and the natural environment. The healing techniques linked with these traditions of knowledge frequently comprise a blend of herbal remedies, rituals, faith, and civic engagement. These practices reflect the interdependence of all elements of life and the necessity to address imbalances at numerous levels for comprehensive healing [110].

For instance, in many Indigenous societies, the usage of herbal remedies plays a fundamental part in healing. These plants are considered to offer great healing powers that help promote equilibrium and enhance well-being. The understanding of these plants and their applications is passed down through generations, indicating an intimate relationship between Indigenous communities and their natural environs [65, 78, 134].

Spirituality is another key component of Indigenous healing traditions. Indigenous cultures generally emphasize the necessity of connecting with the spiritual realm and having a peaceful relationship with ancestors, supernatural beings, and the higher powers. Spiritual rituals and rites are undertaken to correct spiritual deficiencies, maintain peace, and facilitate recovery [20].

Thus, the holistic approach of Indigenous knowledge systems spans beyond the individual to cover the well-being of the community as a whole. All members of the community are considered essential to the healing process. Social bonds, group rituals, and the participation of elders and traditional healers are commonly emphasized in indigenous healing practices [110].

When used as a whole, Indigenous knowledge systems have a profound effect on health that goes far beyond the scope of any single person. Indigenous communities benefit from these structures because they foster a sense of pride, belonging, and cultural continuity [110]. The gap between Western medicine and Indigenous healing practices can be closed by greater recognition and incorporation of Indigenous knowledge into mainstream healthcare systems, hence promoting cultural respect and better health outcomes for Indigenous communities [20].

4.2 Cultural Diversity and Traditional Healing Practices

Traditions, beliefs, and practices that have been passed down from one generation to the next are all part of cultural variety [110]. Traditional medicine is an important part of many different cultures. Different civilizations' historic approaches to health and wellness provide valuable insights into the spiritual dimensions of life. Traditional healing practices have developed over the ages and throughout cultures [86]. Herbal medication, spiritual rituals, energy healing, and mind–body therapies are all included in the broad category of traditional healing.

Traditional medical practices are a reflection of a culture's worldview and medical understanding of illness and health. Traditional healing, for instance, has strong ties to both the natural and spiritual realms in Indigenous cultures (Table 1). Traditional healing for them includes the use of herbs, rituals, and shamanism [110]. These methods promote total health by emphasizing the interdependence of the individual, the group, and the environment.

Traditional Chinese medicine (TCM) has also been practiced for thousands of years and is an integral part of Chinese culture [111]. TCM uses a wide range of techniques, including acupuncture, herbal medicine, and qi gong, to help the body return to a state of health and harmony. The principles of Yin and Yang, Qi (energy), and the dynamic relationship between the various body parts form the foundation of these practices [175].

Because they provide complementary and alternative methods to Western medicine, traditional healing modalities can better meet the requirements of a wide range of people and help to create a more equitable healthcare system [84]. They tend to take into account not only the physical but also the mental and spiritual well-being of their patients. There is growing consensus that underserved groups can benefit from traditional healing practices. Access to care, patient happiness, and patient agency in the healing process are all bolstered by culturally competent practices, according to the literature [71].

For the sake of future generations and the preservation of knowledge, it is essential to protect cultural variety and traditional healing practices. Fostering cultural pride, promoting international collaboration, and contributing to a more inclusive and fair society can all result from encouraging discourse, knowledge, and respect for varied healing traditions.

4.3 Preservation and Transmission of Indigenous Knowledge

Native American, Inuit, and other Indigenous peoples have accumulated and passed on a wealth of expertise through the ages [210]. Indigenous peoples' understanding

Table 1 Some cultures and their healing practices

Cultural diversity	Traditional healing practices	References
Ayurveda	Holistic system of medicine originating in India, focusing on balance and natural remedies	[224, 253]
Traditional Chinese medicine (TCM)	Ancient system of medicine in China was based on balancing Yin and Yang and using herbs, acupuncture, and other modalities	[188, 189]
Indigenous healing practices	Diverse healing practices from indigenous cultures worldwide, often incorporating rituals, plant medicines, and energy work	[73, 203, 6]
Shamanism	Spiritual healing practices involve communication with the spirit world, often through shamans or medicine people	[137, 305]
African traditional medicine	Traditional healing practices are rooted in African cultures, utilizing medicinal plants, divination, and spiritual beliefs	[8, 76, 217]
Unani medicine	Traditional healing system originating from Greece and popular in the Middle East, incorporating natural medicines and humoral theory	[113]
Native American healing practices	Healing practices of Indigenous peoples of North America involve ceremonies, herbal remedies, and sacred rituals	[237]
Australian Aboriginal healing	Traditional healing practices of Aboriginal Australians, including bush medicine, storytelling, and connection to the land	[299]
Tibetan medicine	Traditional healing system of Tibet, integrating herbal medicine, acupuncture, and spiritual practices	[218]
Folk medicine	Traditional healing practices are passed down through generations in various cultures, using local remedies and rituals	[184]
Traditional Mexican healing	Indigenous healing practices of Mexico, combine ancient Aztec and Mayan traditions with Catholicism	[68, 108]
Traditional Korean medicine	The holistic medical system in Korea incorporates acupuncture, herbal medicine, and lifestyle practices	[311]
Amazonian Shamanic healing	Healing practices of Amazonian indigenous tribes, utilizing sacred plants like ayahuasca and traditional ceremonies	[249, 138]
Hmong traditional healing	Healing practices of the Hmong people involve herbal remedies, spiritual rituals, and ancestral beliefs	[245, 310]
Islamic traditional healing	Healing practices are influenced by Islamic teachings, combining faith, prayers, and natural remedies	[102, 242]
Hawaiian traditional healing	Healing practices of Native Hawaiians, known as Lāʼau Lapaʼau, use plants, prayers, and spiritual connection	[149]
Siberian Shamanism	Traditional healing practices of Siberian shamans involve spiritual journeys, rituals, and herbal remedies	[77, 297]
Caribbean traditional healing	Healing practices of Caribbean indigenous cultures, incorporating plant medicine, rituals, and ancestral wisdom	[48]

(continued)

Table 1 (continued)

Cultural diversity	Traditional healing practices	References
Brazilian traditional healing	Traditional healing practices in Brazil, blend indigenous, African, and European influences with plant medicine	[37]
Maori healing	Traditional healing practices of the Maori people of New Zealand, known as Rongoā, use plants and spiritual connection	[186]
Romani (Gypsy) traditional healing	Healing practices of the Romani people, including herbal remedies, divination, and cultural ceremonies	[36]

of the world is intrinsically linked to their homelands, their traditions, and their own identities. There can be no sustainable development, cultural preservation, or community resilience without the transmission of Indigenous knowledge.

It is crucial to preserve Indigenous knowledge to ensure the survival of Indigenous cultures. Indigenous recuperation, ecological understanding, cultural practices, and sustainable resource management are just a few of the many areas that might benefit from Indigenous knowledge, which is grounded in the knowledge and expertise of Indigenous populations. Keeping Indigenous knowledge safe ensures that future generations can learn from the past and continue to feel a deep connection to their heritage.

Many methods are being used in the fight to keep Indigenous knowledge alive. Traditional methods, oral histories, and ecological knowledge can all benefit from careful documentation. Indigenous communities, academics, and researchers can work together to accomplish this [210]. Indigenous knowledge is best protected through documentation, which also serves as a significant resource for learning, teaching, and cultural renewal.

Reviving Indigenous cultural practices inside communities is also crucial to ensuring their survival. Facilitating the transfer of wisdom from older to younger generations is essential to this end. When it comes to preserving and spreading Indigenous knowledge, community-based activities like cultural camps, seminars, and mentorship programs play a crucial role [27]. Communities can benefit from these endeavors because they provide venues where people can discuss and learn about their history and traditions from those who have lived with them the longest.

However, there are considerable obstacles to conserving and passing on Indigenous knowledge. Indigenous knowledge systems have been eroded and lost due to colonization, globalization, and cultural assimilation. The transmission of Indigenous knowledge from one generation to the next has been hampered by historical trauma, forced relocation, and discriminatory laws, according to research by Nicholas and Markey [210]. The problems of conserving and conveying Indigenous knowledge are exacerbated by the decline of languages, the spread of urbanization, and the dominance of dominant cultures.

Together, respect and acknowledgment of Indigenous rights are essential to overcoming these obstacles. Indigenous peoples should have a say in how their knowledge is used and disseminated [27] and be included in the process of decision-making that impacts their knowledge systems. Supporting the safeguarding and propagation of Indigenous knowledge through initiatives like developing curriculum, language rejuvenation, and the integration of Indigenous perspectives into mainstream education can be achieved through the involvement of the indigenous commnities in its planning and implementation [143].

4.4 Contributions of Indigenous Knowledge to Phytochemistry Research

Indigenous knowledge has enhanced phytochemistry studies on medicinal plants and their uses (Table 2). Indigenous peoples know the qualities, uses, and preparation of local flora. This understanding helped find bioactive chemicals, produce novel medications, and advance phytochemical studies. Indigenous knowledge in phytochemistry research and its impact on science are examined in this chapter.

Indigenous knowledge systems have long recognized plant medicine and developed complex strategies for its use. Indigenous knowledge holders – traditional healers – have studied therapeutic plants for ages. This expertise covers medicinal plant identification, components, preparation, and treatment [278].

Native American wisdom is also a valuable resource for information about when and how to harvest plants for maximum bioavailability of their medicinal chemicals and which parts of the plant to use [278].

Artemisinin, a powerful antimalarial chemical, was discovered with the help of Indigenous knowledge and has since become a cornerstone of phytochemistry study. Traditional Chinese medicine practitioners recommended *Artemisia annua* (sweet wormwood) for treating fever and malaria symptoms [314]. Artemisinin, a potent antimalarial medication, was isolated and characterized as a result of research motivated by this ancient knowledge. Millions of lives were spared all around the world thanks to this breakthrough in malaria treatment.

Traditional healing practices and indigenous knowledge have both played important roles in the discovery of new bioactive substances with therapeutic potential. For instance, the Mapuche people of Chile were responsible for the discovery of antibacterial chemicals in the tree *Quillaja saponaria* thanks to their indigenous knowledge. The antibacterial, anticancer, and immunomodulatory effects of these saponins have been the subject of substantial research. Other medicinal plants like *Echinacea purpurea* and *Uncaria tomentosa* (cat's claw) have been discovered thanks to indigenous people's awareness of their bioactive chemicals and possible health benefits [278].

Sustainable practices have been furthered by combining Indigenous wisdom with advances in phytochemistry research. To ensure the continued availability of medicinal herbs, indigenous cultures practice environmentally responsible harvesting methods. Scientists can learn from Indigenous knowledge holders about these eco-friendly methods, and incorporate them into the creation of environmentally and ethically responsible strategies for plant-based therapy [314].

Table 2 Contribution of Indigenous knowledge to phytochemistry research

Contributions	Description	References
Traditional plant selection criteria	Indigenous knowledge provides valuable insights into the selection of plants for phytochemical research	[1]
Ethnobotanical surveys	Indigenous communities' knowledge of medicinal plants guides ethnobotanical surveys, identifying potential sources of bioactive compounds	[195]
Traditional extraction techniques	Indigenous knowledge contributes to the development of traditional extraction methods to isolate bioactive compounds effectively	[295]
Identification of medicinal plants	Indigenous knowledge aids in the accurate identification of medicinal plants, ensuring the use of the correct species for phytochemical analysis	[85]
Traditional knowledge of plant properties	Indigenous knowledge provides information on the medicinal properties of plants, guiding phytochemical studies toward specific therapeutic areas	[257]
Traditional methods of plant preparation	Indigenous knowledge informs traditional methods of plant preparation, influencing the extraction techniques used in phytochemical analysis	[72, 139]
Sustainable harvesting practices	Indigenous knowledge promotes sustainable harvesting practices, ensuring the conservation of medicinal plants for future research and use	[221, 259]
Traditional knowledge of plant conservation	Indigenous knowledge contributes to plant conservation efforts, preserving biodiversity for future phytochemical research and medicinal use	[204]
Traditional pharmacopoeias and formulations	Indigenous pharmacopeias and traditional formulations serve as valuable resources for phytochemical research and drug development	[222]

5 Chemical Composition of Medicinal Plants in Indigenous Knowledge Systems

Traditional Indigenous knowledge and modern scientific inquiry come together in the study of the chemical makeup of medicinal plants. This section identifies the bioactive compounds accountable for the plant's therapeutic properties, thereby lending credence to traditional remedies and opening the door to the development of novel pharmaceuticals.

5.1 Methods and Techniques Used for Phytochemical Analysis

Analysis of medicinal plants via the lens of their chemical components is called phytochemical analysis. The medicinal potential of plants can be better understood through the use of various approaches and techniques for isolating and characterizing bioactive substances (Table 3). Extraction, fractionation, and component identification are common steps in phytochemical investigation.

Table 3 Some methods and techniques used for phytochemical analysis

Method/technique	Description	References
Liquid chromatography-mass spectrometry (LC-MS)	Separation and identification of compounds in complex mixtures	[183]
Gas chromatography-mass spectrometry (GC-MS)	Separation and identification of volatile and semivolatile compounds	[145]
High-performance liquid chromatography (HPLC)	Separation and quantification of individual compounds	[219]
Thin-layer chromatography (TLC)	Separation and identification of compounds using a thin layer of adsorbent	[147]
Nuclear magnetic resonance (NMR)	Structural elucidation and identification of compounds	[19]
Fourier transform infrared spectroscopy (FTIR)	Identification of functional groups and structural analysis	[182]
Ultraviolet-visible spectroscopy (UV-Vis)	Quantification and analysis of compounds based on the absorption of light	[151]
Mass spectrometry imaging (MSI)	Spatial distribution and identification of compounds in tissues	[246]
Capillary electrophoresis (CE)	Separation of charged compounds based on electrophoretic mobility	[263]
Solid-phase microextraction	Extraction and pre-concentration of volatile compounds	[22]
High-resolution mass spectrometry	Accurate mass determination and identification of compounds	[205]
Supercritical fluid extraction	Extraction of compounds using supercritical fluids	[9]
Matrix-assisted laser desorption/ionization	Analysis of large biomolecules and polymers	[58]
Electrochemical analysis	Determination of redox properties and electroactive compounds	[115]
Nuclear magnetic resonance imaging	Imaging and localization of compounds in intact samples	[79]
X-ray diffraction	Structural analysis and identification of crystalline compounds	[275]
Gas chromatography	Separation and analysis of volatile and semivolatile compounds	[160]
Liquid chromatography	Separation and analysis of compounds in liquid samples	[140]
Inductively coupled plasma mass spectrometry	Quantification of trace elements and metals	[159]

Extracting bioactive chemicals from plant materials using appropriate solvents is the first step in phytochemical analysis. Methods such as maceration, Soxhlet extraction, and supercritical fluid extraction (SFE) are frequently used for extraction. Each approach has benefits and drawbacks; which one is chosen depends on the substances of interest and the specifics of the plant being studied [53].

The physical and chemical features of materials can be used in chromatography to separate and purify them [304]. Thus, the phytochemical analysis relies heavily on the identification and characterization of bioactive chemicals. Nuclear magnetic resonance (NMR) and mass spectrometry (MS) spectroscopy are two common spectroscopic methods used to identify compounds. To learn more about the compounds' structures, NMR is used in conjunction with MS [53].

5.2 Medicinal Plants and Their Bioactive Constituents

Bioactive chemicals are the chemical components of medicinal plants that are responsible for the plants' observed biological activity and therapeutic benefits [80, 118, 119, 126, 127] A wide variety of chemical structures, such as alkaloids, flavonoids, terpenoids, and phenolic chemicals, can fall within this category. Antioxidant, antibacterial, anti-inflammatory, and anticancer activity are only some of the many biological effects attributed to bioactive substances [63].

One of the most widely recognized classes of bioactive molecules extracted from plants used for medicine is alkaloids (Table 4). Their pharmacological effects, such as analgesic, antibacterial, and anticancer properties, are sometimes rather strong. Morphine, extracted from the opium poppy (*Papaver somniferum*), and quinine, extracted from the bark of the Cinchona tree (*Cinchona spp*.) [63], are both examples of alkaloids.

Antioxidant and anti-inflammatory characteristics are also possessed by flavonoids, another major class of bioactive chemicals. Fruits, veggies, and medicinal plants all contain these chemicals. Onions (*Allium cepa*) and chamomile (*Matricaria chamomilla*) both contain flavonoids such as quercetin and apigenin, respectively [63].

Aromatic plants typically contain terpenoids, such as essential oils. They have properties that make them effective against microbes, fungi, and insects. Menthol, found in peppermint (*Mentha piperita*), and limonene, found in lemon (*Citrus limon*), are both terpenoids [63].

Understanding the processes that govern the action and therapeutic applications of these medicinal plants requires the isolation and characterization of their bioactive components [116, 121–125]. As either lead molecules or sources of inspiration, they provide the backbone of the drug discovery process [63].

5.3 The Importance of Traditional Knowledge for Locating Medicinal Plants

Medicinal plant identification relies heavily on Indigenous knowledge, which draws from Indigenous communities' centuries-long store of tacit knowledge and experience. Traditional physicians and wisdom keepers have an in-depth familiarity with the native flora and the medicinal benefits of individual plants. This information includes the recognition, preparation, and usage of medicinal plants for diverse ailments, and it is typically transmitted orally. Researchers can take advantage of this wealth of knowledge and focus their hunt for potential medicinal plants by consulting Indigenous knowledge systems.

Table 4 Medicinal plants and their bioactive constituents

Medicinal plant	Bioactive constituents	References
Curcuma longa (Turmeric)	Curcumin, turmerones, curcuminoids	[105]
Panax ginseng (Ginseng)	Ginsenosides, polysaccharides, polyacetylenes	[158]
Hypericum perforatum (St. John's Wort)	Hypericin, hyperforin, flavonoids	[306]
Vinca rosea (periwinkle)	Vinblastine, vincristine, alkaloids	[190]
Camellia sinensis (green tea)	Epigallocatechin gallate (EGCG), catechins	[54]
Ginkgo biloba (ginkgo)	Flavonoids, terpenoids, ginkgolides	[178]
Allium sativum (garlic)	Allicin, sulfur compounds, flavonoids	[3]
Aloe vera	Anthraquinones, polysaccharides, flavonoids	[10]
Salvia officinalis (sage)	Rosmarinic acid, flavonoids, triterpenoids	[97]
Curcuma zedoaria (zedoary)	Curzerene, curcumenol, zedoarondiol	[7]
Silybum marianum (milk thistle)	Silymarin, silybin, flavonolignans	[2]
Echinacea purpurea (purple coneflower)	Alkamides, polysaccharides, flavonoids	[40]
Zingiber officinale (ginger)	Gingerol, shogaol, zingerone	[173]
Centella asiatica (gotu kola)	Asiaticoside, madecassoside, triterpenoids	[236]
Rosmarinus officinalis (rosemary)	Rosmarinic acid, carnosic acid, flavonoids	[293]
Mentha piperita (peppermint)	Menthol, menthone, rosmarinic acid	[194]
Camellia japonica (camellia)	Saponins, tannins, flavonoids	[227]
Cinnamomum verum (cinnamon)	Cinnamaldehyde, cinnamic acid, procyanidins	[31]
Withania somnifera (ashwagandha lehya)	Withanolides, alkaloids, steroids	[29]
Melissa officinalis (lemon balm)	Rosmarinic acid, flavonoids, terpenes	[181]
Matricaria chamomilla (chamomile)	Apigenin, chamazulene, bisabolol	[276]
Glycyrrhiza glabra (licorice)	Glycyrrhizin, flavonoids, coumarins	[239]
Berberis vulgaris (barberry)	Berberine, isoquinoline alkaloids, flavonoids	[114]
Coptis chinensis (goldthread)	Berberine, coptisine, palmatine	[56]
Curcuma aromatica (wild turmeric)	Curcumin, turmerones, curcuminoids	[98]
Urtica dioica (nettle)	Flavonoids, phenolic acids, lectins	[30]
Punica granatum (pomegranate)	Punicalagin, ellagic acid, anthocyanins	[143]

Based on their experiences in the natural world and their knowledge of the relationships between plants, ecosystems, and human health, indigenous knowledge holders have developed complex systems for identifying and selecting medicinal plants [278]. They are experts on the local flora and fauna and can identify plants by sight and sound alone. Traditional medicine identifies certain characteristics in plants as indicators of their therapeutic efficacy. For instance, the anti-inflammatory properties of *Curcuma longa* (turmeric) are indicated by its bright yellow color, and the wound-healing properties of *Calotropis procera* (milkweed) are indicated by the presence of milky latex [278].

Indigenous knowledge also includes an appreciation of how plants influence their surrounding ecosystems and other forms of life. Some plants are known to attract certain insects, animals, or soil types, and this information is used by traditional healers. These connections are extremely helpful for determining whether or not a plant has any therapeutic value. For instance, if certain species of butterflies or bees prefer the nectar of a specific flower, this may indicate that the plant has therapeutic properties [42]. Indigenous knowledge also includes an appreciation of how plants influence their surrounding ecosystems and other forms of life. Traditional practitioners of medicine take note of the connections between plants and their ecosystems, such as the presence or absence of particular insects, animals, or types of soil. Insights into a plant's possible medicinal capabilities can be gleaned from these correlations. If butterflies or bees go toward a particular flower for its nectar, that could indicate the plant has therapeutic properties [42].

The effectiveness and safety of medicinal plants are evaluated by Indigenous knowledge holders based on their own experiences and the knowledge of their communities. This understanding is gleaned from experience gained via the frequent usage of particular plants for medicinal reasons and the subsequent observation of their effects. To ensure the reliability of their selection criteria, indigenous people frequently use prescribed procedures and traditional practices to verify the efficacy of medicinal plants [278].

5.4 Phytochemical Diversity and Classical Methods of Plant Selection

In Indigenous knowledge systems, the rationale for choosing plants is generally based on accumulated observational and empirical information. Plants with potential therapeutic characteristics can be found using these parameters as a starting point. When choosing plants, indigenous peoples think about more than just their looks; they also examine the plants' natural setting, traditional usage, and cultural importance. Because of this selection, medicinal plants have a wide variety of phytochemical substances.

The interdependence of flora, fauna, and human well-being is a central tenet of indigenous knowledge systems. Conventional plant selection criteria think about where plants naturally grow and how they are dispersed [42]. Indigenous peoples have long known that plants' bioactive substances reflect their ecological traits and how they have adapted to their environments. Indigenous cultures make use of the unique chemical profiles of plants that have adapted to different conditions by selecting plants from places like high-altitude regions and coastal areas.

Indigenous knowledge systems also consider a plant's morphology when deciding which plants to use as medicines. Certain characteristics of plants have been linked by traditional healers' observation to beneficial effects. As stated by

Bussmann et al. [42], visual and sensory indications of medicinal potential include color, shape, texture, and scent. There is some evidence that antioxidant selection favors plants with red pigments, while antimicrobial selection favors those with strong smells.

Cultural value and Indigenous people's accumulated knowledge also factor into the traditional plant selection criteria. Medicinal plants with deep cultural roots tend to be given more attention. Plant selection criteria are influenced by indigenous groups' respect for and sharing of their predecessors' knowledge and experiences [278]. Some cultures place a high value on plants because of their significance in rituals and folklore.

Indigenous knowledge systems employ a wide variety of selection factors for choosing medicinal plants, which increases their phytochemical diversity. Plants contain a broad variety of bioactive substances, such as alkaloids, flavonoids, terpenoids, and phenolic compounds, which are together referred to as phytochemical diversity. The medicinal benefits of plants are based in part on the distinct chemical compounds that are produced by each species.

Indigenous tribes increase the number of plants with useful phytochemical compounds by using traditional plant selection criteria to include them in their pharmacopeias. The chance of finding new bioactive chemicals with pharmaceutical applications is boosted by this phytochemical variety. Thus, indigenous knowledge systems aid in the search for therapeutic plants by providing useful information about how to choose plants with a wide range of chemical constituents.

6 Traditional Healing Practices and Their Phytochemical Foundations

The use of medicinal plants is common in traditional healing practices since they are based on accumulated cultural knowledge. Various phytochemical substances found in these plants give them their medicinal effects. Hence, there is a need for insight into the efficacy and potential of these ancient medicinal practices to understand their phytochemical roots.

6.1 Traditional Healing Systems and Their Philosophies

Different cultures all over the world have evolved and passed down their own unique sets of beliefs and practices when it comes to traditional healing. The values and beliefs of the people from which these systems sprang are the bedrock upon which they stand.

The idea that everything in life is interrelated is central to many different types of alternative medicine. Traditional healers understand the linked nature of a person's bodily, mental, cognitive, and spiritual health. To them, health is achieved when all of these components are in tune with one another. For instance, the Yin and Yang theory is central to traditional Chinese medicine (TCM), which stresses the

Table 5 Some traditional healing systems and their philosophies

Traditional healing systems	Philosophies	References
Ayurveda	Holistic approach to balance body and mind	[282]
Traditional Chinese medicine	Balance of Yin and Yang, Qi flow	[188]
Unani medicine	Balancing the four humors, vital force	[13]
Indigenous medicine	Harmony with nature, interconnectedness	[1]
Siddha medicine	Balance of elements and energy	[104]
Shamanism	Interaction with spirits and energies	[164]
Traditional African medicine	Ancestral spirits, energy balance	[300]
Native American medicine	Connection to nature, spirit guides	[274]
Traditional Korean medicine	Balance of Yin and Yang, Qi flow	[60]
Tibetan medicine	Balance of three humors, mind-body–spirit unity	[38]
Kampo medicine	Balance of Qi and body fluids	[269]
Australian Aboriginal medicine	Connection to land, dreamtime	[251]
Hmong traditional medicine	Balance of elements and energies	[281]
Native Hawaiian medicine	Connection to land and ancestors	[41]
Amazonian traditional medicine	Connection to the rainforest, plant spirits	[43]
Islamic medicine	Balance of bodily humors and spiritual well-being	[234]
Traditional Mexican medicine	Connection to Aztec and Mayan traditions	[44]
Maori Rongoā medicine	Connection to ancestors, spiritual healing	[301]

importance of maintaining a healthy equilibrium between seemingly opposed energies (Table 5).

Traditional medical tenets also place a premium on tailoring treatments to the specific needs of each patient. Because of this, traditional healers customize their care for each patient based on their distinctive characteristics and the nature of their illness or injury. This individualized treatment plan considers the whole person, not just their physical ailments. Traditional Native American medicine, for example, seeks to balance both the individual and the group [110].

Preventative care and general wellness upkeep are fundamental tenets of both modern and traditional medical philosophies. The systems in question place a premium on taking preventative actions for one's health. Traditional healing systems typically include practices such as recommending good lifestyle choices, nutritional guidelines, and stress reduction strategies. The goal of Ayurveda, India's traditional healing practice, is to avoid sickness by promoting health through a balanced way of living [95].

Often at the center of the ideologies of traditional healing methods are spirituality and the acknowledgment of a higher power Spiritual rituals, prayer, and communion with a higher power are integral parts of many time-honored approaches to healthcare. According to proponents of alternative medicine, one's emotional and physical health are inextricably linked. To re-establish the balance between the spiritual and material worlds, for instance, ceremonies and rituals are frequently incorporated into Indigenous healing practices [110].

The core tenets of conventional medical philosophies stress the significance of considering the whole person when treating illness or injury. Traditional healers understand the interconnected nature of a person's bodily, emotional, mental, and spiritual selves. Traditional healing systems seek to establish balance and harmony by attending to these facets as a whole, so bolstering the well-being of individuals and communities. Thus, underlying traditional treatment systems prioritize respect for the whole person, attention to detail, a focus on prevention, and a spiritual dimension. These beliefs underpin comprehensive strategies for health and well-being, which take into account the connections between a person's mental, emotional, and spiritual states.

6.2 Traditional Diagnosis and Treatment Methods

An essential aspect of any traditional healing system is the use of tried-and-true methods of diagnosis and treatment that have been passed down through the generations. These strategies are part of a more all-encompassing approach to healthcare that takes into account the patient as a whole, not just their physical symptoms. To promote holistic and individualized care, this chapter delves into the history of conventional approaches to diagnosis and therapy.

Observations, interviews, and tests are all components of the conventional diagnostic process. To diagnose a patient, traditional healers must rely on the five senses and their intuition. They learn about a person's health by observing outward manifestations of it, such as skin tone, facial expressions, and bodily movements [308]. Additional information on manifestations, history of illness, way of life, and emotional well-being can be gleaned from chats and interviews with the individual and their family. Traditional healers can establish a holistic picture of an individual's health and detect imbalances or disharmony by taking this all-encompassing approach.

Energy flow and balance are fundamental to both assessment and treatment in traditional healing modalities (Table 6). To heal from disease, according to traditional healers, one must first restore energy balance. For instance, in traditional Chinese medicine (TCM), abnormalities in the body's energy can be determined through pulse diagnosis and tongue examination [169]. Feeling the pulse at several locations on the wrist can reveal information about the health of various organs by picking up on variations in the pulse's quality, rhythm, and strength. Examination of the tongue can reveal information about a person's general health and the state of several organs. These diagnostic tools aid in making treatment decisions that bring about equilibrium and health.

Herbal therapy, acupuncture, massage, spiritual rituals, nutritional advice, and lifestyle changes are just a few of the many modalities that make up traditional treatment methods. In many alternative medical practices, plants and plant extracts

Table 6 Some traditional diagnosis and treatment methods

Traditional method	Description	References
Ayurveda pulse diagnosis	Assessment of health through pulse examination	[96]
Traditional Chinese medicine (TCM) diagnosis	Pattern differentiation based on Yin-Yang and five-element theory	[176]
Unani humoral diagnosis	Diagnosis based on the balance of four humors (blood, phlegm, yellow bile, black bile)	[94]
Indigenous Shamanic diagnosis	Communication with spirits and ancestors for diagnosis and treatment	[35]
Native American medicine diagnosis	Connection to nature, visions, and dreams for diagnosis	[185]
Tibetan medicine pulse diagnosis	Examination of the pulse for diagnosing imbalances and diseases	[211]
African divination methods	Interpretation of signs, symbols, and rituals for diagnosis and treatment	[215]
Kampo diagnosis	Assessment based on the theory of Qi and pattern identification	[213]
Native Hawaiian Ho′oponopono	Emotional and spiritual healing through reconciliation and forgiveness	[146]
Mexican Curanderismo diagnosis	Observation, palpation, and use of prayer for diagnosis and treatment	[174]
Korean Sasang constitutional medicine diagnosis	Assessment based on individual constitutional types and imbalances	[214]
Australian Aboriginal dreamtime healing	Connection to land, dreaming, and ancestral guidance for diagnosis and treatment	[198]
Hmong spirituality and rituals	Communication with spirits and use of rituals for diagnosis and healing	[47]
Native American sweat lodge	Purification and spiritual healing through sweat baths	[90]
Maori Rongoā traditional diagnosis	Observation, inquiry, and spiritual connection for diagnosis and treatment	[187]
Amazonian Shamanic diagnosis	Interaction with spirits and use of medicinal plants for diagnosis and treatment	[45]
Islamic Tibb diagnosis	Assessment based on the balance of body, mind, and soul	[112]
Traditional Mexican Sobadores	Manual manipulation, massage, and herbal remedies for diagnosis and treatment	[232]

are used as therapeutic tools. To treat their patients, traditional healers use their extensive knowledge of medicinal plants and their therapeutic characteristics to create unique herbal treatments [278]. Acupuncture is a key component of TCM, and it involves inserting very thin needles into the body at strategic spots along energy meridians to balance the flow of chi and induce healing. Ayurvedic massage and other forms of indigenous bodywork are two types of massage that focus on re-establishing equilibrium and improving blood flow.

Traditional healing practices also make use of spiritual ceremonies and rituals. Invoking the spirit world, making contact with ancestors or deities, and praying to them are all part of these healing rites. Prayer, chanting, smudging, and the usage of sacred artifacts are all examples of spiritual healing rituals [110]. These methods take into account the fact that one's physical, mental, emotional, and spiritual health are all intertwined and work to revitalize each of these areas.

A personalized and patient-centered focus is common in conventional medical practice. When treating a patient, traditional healers consider the person's history, lifestyle choices, and cultural context. Individualized meal plans, healing exercises and stretches, and tips for improving one's quality of life are all components of effective treatment regimens [308]. Such individualized attention promotes patient agency and active participation in their recovery by ensuring that treatment is tailored to their unique medical needs.

6.3 Phytochemical Basis of Traditional Healing Practices

Cultures all across the world have relied on time-tested methods of healing for hundreds of years. The use of medicinal plants and their derivatives is a common component of these practices. The presence of these plants' phytochemicals has been linked to the success of traditional healing methods. To put it simply, phytochemicals are substances found in plants that have biological activity and may contribute to their therapeutic effects. The traditional usage of plants for healing can be supported and expanded upon by learning more about the phytochemical underpinnings of these practices.

Traditional therapeutic practices such as India's Ayurvedic medicine are one example. The efficacy of the many different medicinal plants used in Ayurvedic medicine is often credited to the plants' phytochemical components. Curcumin, the active ingredient in turmeric (*Curcuma longa*), has been the subject of much research due to its anti-inflammatory, antioxidant, and anticancer characteristics [224]. Similarly, it has been established that the ginsenosides in *Panax ginseng* have adaptogenic, immunomodulatory, and neuroprotective properties [290].

Similarly, medicinal plants have a significant role in traditional Chinese medicine (TCM). In TCM, internal harmony and equilibrium are paramount. Phytochemicals are a key component of many TCM medicinal plants' therapeutic properties. Artemisinin, isolated from the herb *Artemisia annua,* is a powerful antimalarial drug (Leung and Wong 2021). Anti-inflammatory, antiviral, and anticancer properties are among the many pharmacological activities indicated by the bioactive chemicals found in TCM plants.

Medicinal herbs are used in indigenous healing practices throughout the world. These methods frequently necessitate an in-depth familiarity with the indigenous flora and its therapeutic characteristics. Native American societies in North America have long relied on the immune-boosting and antiviral capabilities of herbs like

Echinacea purpurea and *Sambucus nigra* [298]. The medicinal effects of these plants can be attributed in part to the presence of phytochemicals such polysaccharides, flavonoids, and phenolic compounds.

Traditional therapeutic modalities draw on the phytochemical base of a wide range of plant species. The therapeutic efficacy of herbs is typically multiplied in traditional herbal formulations because of the synergistic effect of combining numerous plant constituents. Plant mixtures with synergistic phytochemical profiles are more effective than single plant preparations [254]. Traditional remedies such as Triphala in Ayurveda are illustrative of this synergistic effect as they combine the fruits of three plants (*Emblica officinalis, Terminalia chebula*, and *Terminalia bellerica*). Antioxidant, anti-inflammatory, and cancer-preventing effects have all been observed in studies using Triphala.

Bioactive phytochemicals have been found in traditional therapeutic plants, according to recent scientific studies. These investigations into phytochemicals' pharmacokinetics and pharmacodynamics have shed light on their possible medicinal effects. The identification and quantification of medicinal plants' phytochemical ingredients have been aided by developments in phytochemical analysis techniques including liquid chromatography-mass spectrometry (LC-MS) and nuclear magnetic resonance (NMR).

6.4 Traditional Healing Rituals and Their Influence on Phytochemistry

Throughout history, traditional healing rituals have played a crucial role in the health and well-being of people from a wide range of cultural backgrounds. The phytochemistry of medicinal plants is profoundly affected by the rituals in which they are used [126–129]. A vast variety of rituals, from spiritual rites to the preparation and administration of herbal treatments, make up traditional healing practices. Traditional practices that incorporate an understanding of the phytochemical components of medicinal plants have helped to ensure their survival.

The Ayahuasca ceremony is a traditional healing ritual performed by natives of the Amazon rainforest. The *Banisteriopsis caapi* vine, together with other plants, is used to create a psychedelic drink known as ayahuasca. Participants in the ceremony are led by the shaman through a process of personal transformation that is thought to promote emotional, mental, and spiritual well-being. Phytochemical analyses have revealed that Ayahuasca plants like *Psychotria viridis* and *Diplopterys cabrerana* contain chemicals including N, N-dimethyltryptamine (DMT), and harmine. The psychedelic effects of Ayahuasca have been linked to the presence of these bioactive ingredients in the plants [243].

Acupuncture is largely accepted as a legitimate medical modality within TCM. The goal of acupuncture is to restore the natural flow of life force energy (Qi) through the body by inserting very fine needles into precise sites along the body's meridians. In addition to acupuncture, several herbal formulae are also employed to treat a wide range of conditions. Gui Zhi Tang, a traditional Chinese medicine formulation, has been scientifically proven to include bioactive chemicals including cinnamaldehyde thanks to the inclusion of the herb *Cinnamomum cassia*. The historic usage of the formula for pain treatment is supported by the chemicals' anti-inflammatory and analgesic effects [55].

Medicinal plant phytochemistry is heavily influenced by traditional indigenous healing practices. Smudging is a ritual in which sacred plants are burned to clear the air and encourage healing; it is widespread in Native American cultures. Sacred plants include white sage (*Salvia apiana*) and cedar (*Thuja* species). The aromatic qualities and possible antibacterial benefits of these herbs come from volatile components like terpenes and phenolic chemicals. Cineole and thujone, among other chemicals, have been isolated from these plants through phytochemical study [226]. The presence of these bioactive substances lends credence to the age-old practice of smudging as a means of purification and spiritual upliftment.

Traditional healing practices like these illustrate the relationship between phytochemistry and medicinal plants. Knowledge of medicinal plant identification, preparation, and application has been preserved and passed down through traditional ceremonies. Scientific support for their traditional use is found through the phytochemical study of these plants, which also confirms the presence of bioactive chemicals responsible for their medicinal qualities.

7 Traditional Herbal Remedies: An Intertwining of Culture and Phytochemistry

This section analyses how traditional herbal remedies are used, which reflects the diverse cultural heritage of people all over the world. Their effectiveness is frequently credited to the intricate interactions between phytochemical components and the human body.

7.1 Traditional Herbal Formulations and Their Preparation

For centuries, people have been making and using herbal remedies that adhere to precise protocols that have been passed down through oral history and cultural norms (Sharma et al. 2020). The specific cultural environment and prevailing body of traditional knowledge determine the range of possible approaches (Table 7).

Herbal formulations are commonly made by methods including decoction, powdering, and oil extraction in Ayurveda, India's traditional medical system (Sharma et al. 2020). To make a decoction, plants are combined and boiled in water to release their medicinal properties. Herbs can be powdered and utilized internally or topically after being ground into a fine powder. The therapeutic properties of herbs are extracted by oil extraction techniques like taila and sneha kalpana by boiling the herbs in a specific oil or ghee [279].

Decoction, soaking, and steaming are also common methods of preparation for herbal formulations in TCM [247]. To make a decoction, plants are boiled together in

Table 7 Some traditional Indian herbal formulations and their preparation

Traditional herbal formulation	Preparations	References
Triphala	Decoction, powder, capsules	[250]
Chyawanprash	Jam-like confection	[264]
Ashwagandhadi lehya	Herbal jam	[235]
Maha Sudarshan Churna	Herbal powder	[51]
Hingvadi Churna	Herbal powder	[23]
Rasayana Churna	Herbal powder	[267]
Bhringarajasava	Fermented herbal tonic	[220]
Panchagavya Ghrita	Medicated ghee	[264]
Chandanasava	Fermented herbal tonic	[296]
Brahmi Ghrita	Medicated ghee	[148]
Shilajit Rasayan Vati	Mineral and herbal tablets	[303]
Chandraprabha Vati	Herbal tablets	[264]
Mahanarayan oil	Herbal oil	[50]
Mahamanjisthadi Kwath	Herbal decoction	[270]

water, usually in predetermined amounts and times, to draw out their medicinal properties. Herbs can be soaked to extract their healing properties by submerging them in a liquid like wine or vinegar for an allotted amount of time. Herbs' medicinal capabilities and flavor profiles can be altered by the steaming process.

The World Health Organization [307] notes that in traditional African medicine, herbal formulations frequently involve infusion, maceration, or fermentation. Herbs' medicinal properties can be extracted by infusion by steeping them in hot water. Maceration is the process of soaking plants in a liquid (often water or alcohol) for a set amount of time to extract active chemicals that have therapeutic effects. Fermentation is the process of transforming and enhancing the therapeutic properties of herbs by allowing them to undergo microbial fermentation in a liquid.

It is worth noting that the ingredients and methods used to prepare traditional herbal remedies have significant cultural and historical roots. The recipes and methods used to make them are usually unique to a given region or community and have been passed down through the generations. It is vital to respect and conserve the old methods and knowledge systems while there is a growing interest in modernizing the creation of traditional herbal compositions. These preparations are effective and holistic because of the cultural background and traditional wisdom that went into them.

7.2 Combining Multiple Plant Ingredients for Synergistic Effects

Herbal formulations often contain several different plants, each used for different purposes [11, 12, 130]. This strategy stems from the idea that complementary interactions between different plant components can boost treatment outcomes.

Each plant was chosen for its intended medical characteristics and how well it would work with the others.

Ayurveda, TCM, and traditional African medicine are just a few examples of traditional medical systems that have long understood the benefits of mixing herbs for synergistic effects. A person's distinctive make-up and the root causes of imbalance or sickness are central to the holistic therapeutic emphases of these systems.

When many herbs are combined into one concoction, practitioners of Ayurveda refer to it as a "herbal formula" or "polyherbal preparation." These preparations are developed to treat particular ailments by combining herbs with synergistic qualities. Classical Ayurvedic formulations like "Triphala" blend three fruits for a variety of health benefits [230]: *Terminalia chebula*, *Terminalia bellerica*, and *Emblica officinalis*.

Herbal formulae in traditional Chinese medicine (TCM) are generally composed of many herbs that function synergistically to reestablish harmony and improve health. When putting together a prescription, it is important to think about how each herb will work with the others. To nourish Yin, tonify the kidneys, and promote the body's vitality, for example, the TCM prescription "Liu Wei Di Huang Wan" comprises six herbs [268].

Multiple plant elements are often combined in traditional African medicine to increase their medicinal benefits. In West Africa, a popular herbal remedy called "Agbo" combines the healing powers of many plants. These preparations are often formulated for individual patients and are effective in treating a wide variety of diseases and disorders [76].

Multiple plant components are included because of the potential for synergistic interactions between their bioactive constituents. Alkaloids, flavonoids, terpenoids, and phenolic compounds are only a few examples of phytochemicals that can be found in various plants and combined to create a more powerful medicinal impact [209].

The potential advantages of mixing plant substances have also been recognized by scientific inquiry. Antioxidant, anti-inflammatory, antibacterial, and anticancer effects of specific herbal combinations have been demonstrated to be significantly higher than those of single plant extracts. Multiple mechanisms, such as the modification of signaling pathways, enhanced bioavailability, and enhanced cellular absorption of active substances, have been proposed to underlie these synergistic effects [309] (Table 8).

7.3 Indigenous Practices of Herbal Medicine Safety and Quality Control

Traditional herbal therapy has a long and substantial history of use in healthcare systems around the world. To guarantee the efficacy and safety of herbal treatments, these procedures frequently incorporate safety safeguards and quality control processes. For example, many indigenous peoples have their own methods for

Table 8 Combination of multiple plant ingredients for synergistic effects

Indigenous medicine system	Herbal formulation	Plant ingredients	Synergistic effects	References
Ayurveda	Triphala	*Terminalia chebula, Terminalia bellerica, Emblica officinalis*	Promotes digestion, detoxification, and overall well-being	[18]
Traditional Chinese medicine (TCM)	Liu Wei Di Huang Wan	*Rehmannia glutinosa, Dioscorea opposita, Cornus officinalis, Alisma orientale, Poria cocos*	Nourishes yin, tonifies kidneys, and supports vitality	[57]
Indigenous medicine (West Africa)	Agbo	Various combinations of medicinal plants	Used for a wide range of ailments	[76]
Native American	Four Thieves Vinegar	Garlic, rosemary, sage, thyme, lavender, and other aromatic herbs	Antimicrobial, antiviral, and anti-inflammatory properties	[74]
Maori medicine (New Zealand)	Kawakawa balm	*Macropiper excelsum* (Kawakawa), combined with carrier oils or beeswax	Soothes skin irritations, eases muscle and joint pain	[103]
Mayan medicine (Maya, Mexico)	Xunan Kab	*Artemisia vulgaris, Simmondsia chinensis, Haematoxylum brasiletto, Calophyllum brasiliense*	Treats menstrual disorders, strengthens reproductive health	[233]
Aboriginal medicine (Indigenous peoples of North America)	Smudging	Sage, sweetgrass, cedar	Cleansing, purifying, and spiritual rituals	[252]
Traditional Hawaiian medicine (Lomilomi)	La'au Lapa'au	Noni, Kukui, Awapuhi, Olena	Healing various ailments and injuries	[165]
Inuit medicine (Inuit, Arctic)	Aakulujjusi	Labrador tea, crowberry, Arctic willow	Promotes physical and mental well-being	[17]
Traditional Amazonian medicine (Shamanism)	Ayahuasca	*Banisteriopsis caapi, Psychotria viridis*	Spiritual and healing ceremonies	[144]

Table 9 Indigenous practices for herbal medicine safety and quality control

Indigenous practice	Description	References
Ethnobotanical knowledge	In-depth understanding of traditional plant uses and safety precautions based on indigenous knowledge systems	[196]
Gathering and harvesting practices	Sustainable collection of medicinal plants, considering specific seasons, plant parts, and growth stages	[49]
Preparation methods	Traditional techniques such as decoction, infusion, maceration, or fermentation, ensuring optimal extraction of active constituents	[179]
Dosage and administration	Customary guidelines for dosage, frequency, and duration of herbal treatments, considering individual characteristics and specific conditions	[14]
Adverse event monitoring	Recognition and documentation of any adverse effects or interactions through continuous observation and communication within the community	[271]
Quality assessment	Traditional methods of assessing herbal quality, such as organoleptic evaluation, sensory perception, and specific tests for authenticity and purity	[289]
Conservation strategies	Indigenous practices for sustainable use, conservation, and cultivation of medicinal plants, including sacred groves and community-managed gardens	[168]
Traditional practitioner training	Apprenticeship and mentorship, passing down knowledge, skills, and ethical practices to future generations of healers	[34]
Collaboration with modern science	Integration of traditional knowledge with scientific research for safety evaluation, efficacy studies, and development of evidence-based practices	[107]

determining whether or not herbal remedies are safe to use. Observation, experience, and following established procedures are common components of such methods (Table 9). For instance, rongo is a practice used by the Maori people of New Zealand that entails the precise identification, preparation, and administration of plants in accordance with cultural protocols and conventional wisdom [180]. Many different indigenous cultures around the world, like the Quechua of the Andes, the Aboriginal of Australia, and the Native American tribes of North America, share similar rituals and beliefs.

Additionally, indigenous herbal medicine systems are dependent on traditional quality control practices. Traditional indigenous healers typically have years of education and apprenticeship under their belts before they are allowed to practice independently. To select the right species and use plants obtained at the right time and under the best conditions, these practices are guided by specialized rituals, cultural norms, and traditional ecological knowledge [278]. The purity and effectiveness of herbal medicines are maintained in part by indigenous tribes' emphasis on the need of precise plant identification and harvesting procedures.

The importance of indigenous knowledge systems in ensuring the quality and safety of herbal medicines has been increasingly acknowledged in recent years. The goal of cooperative projects between indigenous people and contemporary scientific organizations is to lessen the chasm between the two. This partnership utilizes cutting-edge analytical methods for quality control without compromising indigenous people's cultural norms, ethics, or IP rights.

To identify and quantify bioactive chemicals in medicinal plants, analytical techniques like high-performance liquid chromatography (HPLC), gas chromatography-mass spectrometry (GC-MS), and nuclear magnetic resonance (NMR) spectroscopy are used [170]. These methods are helpful for determining the chemical make-up of herbal medicines, which is essential for quality assurance, standardization, and the elimination of any potentially dangerous chemicals or adulterants.

Guidelines and regulatory frameworks that incorporate traditional knowledge into herbal medicine safety and quality control are now under development. The World Health Organization (WHO) has produced guidelines to help member nations set up regulatory frameworks for traditional medicine items including herbal medicines that guarantee their safety, efficacy, and quality [33].

The intellectual property rights of indigenous tribes must be recognized and respected before their traditional knowledge can be used in scientific study or for commercial purposes. A framework for guaranteeing the fair and equitable sharing of advantages generated from traditional knowledge and genetic resources is provided by the Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Advantages Arising from Their Utilisation [109].

8 Indigenous Wisdom as a Treasure Trove of Phytochemical Discoveries and Biodiversity Conservation

Indigenous peoples' relationships with their ecosystems, particularly the many plant species therein, form the foundation of their knowledge systems. Insights into the healing powers of plants and the need to preserve biodiversity can be found in this knowledge, which is a veritable treasure trove of phytochemical findings (Table 10).

Traditional plant identification and therapeutic use have long been depended upon by indigenous populations. Intricate knowledge of the medicinal powers of plants has been acquired by indigenous healers via meticulously observing, exploring, and transferring of expertise from one era to the next. Specific plant components, methods of preparation, and dosages for various conditions are commonly included in this body of knowledge [34]. Many phytochemicals with important medical significance have been discovered thanks to indigenous knowledge.

Indigenous Amazonians, for instance, know everything about the plants in their rainforest that may treat various ailments. Their knowledge helped determine that the Cinchona tree (*Cinchona* species), namely its bark, contains the antimalarial chem-

Table 10 Indigenous wisdom in phytochemical discoveries and biodiversity conservation

Indigenous wisdom	Description and examples	References
Traditional ecological knowledge (TEK)	Indigenous communities possess extensive knowledge about their ecosystems and the interconnections between species. They have developed sustainable practices for managing biodiversity and conserving medicinal plants. For instance, the Indigenous people of the Amazon rainforest employ agroforestry techniques, such as cultivating medicinal plants alongside food crops, to maintain biodiversity	[27, 229]
Sacred sites and rituals	Indigenous cultures often recognize certain areas as sacred sites, considering them crucial for the protection and preservation of biodiversity and medicinal plants. These sites are protected through cultural practices, rituals, and taboos that restrict access and promote sustainable use. The Maasai people of East Africa, for example, have sacred groves where medicinal plants are conserved and only used in specific rituals	[65, 66, 131, 286, 288]
Traditional resource management systems	Indigenous communities have intricate resource management systems that promote the sustainable use and conservation of medicinal plants. These systems include rules, regulations, and community-led governance mechanisms to ensure the responsible harvesting and cultivation of medicinal plants. The Quechua people in the Andes practice "ayllu," a collective farming system that includes the cultivation and conservation of medicinal plants	[135, 283, 294]
Inter-generational knowledge transmission	Indigenous knowledge about biodiversity and medicinal plants is passed down through generations via oral traditions, storytelling, and apprenticeship. Elders play a crucial role in transferring knowledge to younger community members, ensuring the continuity of traditional practices and conservation efforts. The Indigenous communities of Australia have a strong oral tradition, where elders teach the younger generation about the identification, preparation, and sustainable harvesting of medicinal plants.	[61, 152]
Traditional conservation practices	Indigenous communities have developed unique conservation practices that are deeply rooted in their cultural beliefs and spiritual connections to nature. These practices often involve seasonal harvesting, rotational cultivation, and the protection of specific areas to allow natural regeneration. The Kuna people of Panama, for instance, have established marine protected areas to safeguard marine biodiversity and medicinal plant resources.	[201, 216]

ical quinine [258]. Similarly, the antimalarial effects of plants like *Cryptolepis sanguinolenta* have been uncovered by the traditional healing practices of the Maasai culture in East Africa [69].

When it comes to protecting biodiversity, indigenous knowledge is just as important. Native peoples have a deep emotional investment in their homelands and have created environmentally friendly methods of living that help protect endangered plant species and entire ecosystems. Sustainable ways of gathering medicinal plants, guarding sacred sites, and maintaining traditional landscapes are all within their sphere of expertise [231].

Native crops such as quinoa (*Chenopodium quinoa*), amaranth (*Amaranthus* species), and many medicinal plants have been cultivated and preserved by the Quechua people of the Andean region in South America for centuries [241]. Because of their dedication to sustainable farming methods, the region's rich plant life has been preserved for future generations.

When it comes to the use of medicinal plants and the protection of biodiversity, indigenous knowledge systems provide a more comprehensive perspective. They shed light on the need for harmony and balance in the natural world by showing how people and plants are interdependent. Traditional knowledge from local communities can help scientists learn more about the potential medicinal uses of plants and develop more effective conservation strategies [89].

In summary, traditional knowledge is an important tool for exploring new phytochemicals and protecting existing species. Sustainable practices and in-depth knowledge of medicinal plants among indigenous tribe's aid in the discovery of important bioactive components and the protection of endangered plant species. Sustainable use of plant resources and protection of cultural and ecological variety depends on the recognition and respect of indigenous knowledge systems.

9 Challenges and Ethical Considerations in Indigenous Knowledge Research

To work in a way that is both respectful and equitable with indigenous populations, researchers examining indigenous knowledge must first face several particular obstacles and ethical considerations (Table 11). The complicated background of colonization, power disparities, and the desire to protect cultural rights and patents all contribute to these difficulties. Research that upholds indigenous rights, creates fruitful relationships, and encourages the preservation and revival of indigenous knowledge systems requires an appreciation for and response to these obstacles.

Written authorization and community engagement is a major obstacle to advancing indigenous knowledge research. Involving indigenous people early on in the research process is crucial for obtaining their express, informed, and free permission and ensuring their active participation. Trust and collaborative partnerships based on mutual respect and collaboration are essential for researchers. To ensure the research is in line with the community's interests, values, and cultural norms, this procedure

Table 11 Challenges and ethical considerations in indigenous knowledge research

Challenges	Ethical considerations	Authors
Knowledge ownership	Recognizing and respecting Indigenous knowledge holders' rights to control and own their knowledge	[26, 273]
Cultural appropriation	Avoiding the appropriation or exploitation of Indigenous knowledge and ensuring appropriate attribution	[62, 228]
Informed consent	Obtaining free, prior, and informed consent from Indigenous communities, individuals, and knowledge holders	[24, 197]
Power imbalances	Acknowledging and addressing power imbalances between researchers and Indigenous communities during the research process	[100, 244]
Intellectual property rights	Protecting Indigenous intellectual property rights and ensuring fair and equitable benefit-sharing	[32, 202]
Community engagement	Engaging with Indigenous communities in a meaningful and collaborative manner throughout the research process	[88, 292]
Confidentiality and privacy	Respecting the confidentiality and privacy of Indigenous knowledge holders and community-specific information	[150, 161]
Data sovereignty	Recognizing Indigenous communities' rights to control and manage their own data, including Indigenous data sovereignty	[192, 200]
Research methodologies	Adopting culturally appropriate research methodologies and frameworks that align with Indigenous worldviews and knowledge systems	[15, 273]
Preservation of cultural integrity	Preserving and promoting the cultural integrity, values, and practices associated with Indigenous knowledge	[273, 46]

may incorporate community standards, research agreements, and continuing participation [4, 273].

Another difficulty could be the theft or misuse of traditional information. Researchers face a balancing act between doing what's best for humanity and respecting the rights of indigenous peoples to their intellectual property and cultural traditions. In order to act ethically, it is important to gain permission before using indigenous knowledge, give credit where credit is due, and divide any rewards fairly among those who contributed to the discovery. The Nagoya Protocol and similar initiatives provide best practices for the equitable and fair distribution of benefits accruing from the use of traditional knowledge.

Indigenous knowledge studies must also take into account cultural appropriateness and cultural security. Researchers have a responsibility to be sensitive to local customs, refrain from plagiarizing someone else's work, and not offend anyone throughout the course of their investigation. Reflexive practices are important because they force the researcher to reflect on his or her own positionality, biases, and the power dynamics at play in the research. Respect for native cultures, languages, and methods of knowing is essential. This includes acknowledging the variety among indigenous groups.

Furthermore, great care must be taken in the reporting and sharing of study results. Indigenous peoples should have a say in the dissemination of their knowledge, and the results of research should be presented in a respectful way that allows for community input. Feedback loops and community involvement in knowledge translation activities are examples of open and transparent communication that can help ensure research benefits the community and is in line with their self-determined goals [28, 93].

Ethical indigenous knowledge research also places a premium on creating local capacity and sharing existing expertise. Learning from and teaching indigenous peoples, as well as helping to preserve and revitalize indigenous knowledge systems, should be high priorities for researchers. Sharing research results, facilitating community-led research projects, and enabling indigenous people to document, administer, and apply their own knowledge are all essential steps in this direction [46].

10 Collaborative Approaches That Respect and Safeguard Indigenous Knowledge

To ensure that research processes and findings are congruent with the values, needs, and ambitions of Indigenous people, collaborative approaches are vital for honoring and safeguarding Indigenous knowledge. Honoring Indigenous knowledge systems, fostering self-determination, and supporting the preservation and revitalization of traditional practices can be accomplished when researchers engage in meaningful relationships and employ inclusive techniques. These cooperative methods originate from the values of equality, fairness, and consensus (Table 12).

One important method that includes Indigenous populations in the study process is called participatory research. It goes beyond simple consultation to include Indigenous knowledge bearers at all stages of the research process, from conception to execution. This strategy places Indigenous peoples at the center of the research process, giving them credit for their knowledge and insights [273, 313].

Collaborative methods also heavily rely on indigenous research frameworks. Indigenous values, philosophies, and practices inform these models. They incorporate cultural practices and storytelling and place an emphasis on holistic approaches that respect community values. Researchers are guided in performing research that is in accordance with Indigenous protocols, honors cultural practices, and represents Indigenous ways of knowing by using Indigenous research methodology like Two-Eyed Seeing, yarning circles, and Two-Spirit research procedures. Researchers show they value Indigenous knowledge by using these frameworks [163, 162] and so producing results that are culturally suitable and relevant.

Knowledge sharing and creation are at the heart of collaborative methods. Researchers in these collaborations deliberately seek out opportunities for conver-

Table 12 Types of collaborative approaches that respects and safeguard indigenous knowledge

Collaborative approaches	Description and examples	References
Participatory research	Adopting participatory research methodologies that actively involve Indigenous communities in the research process. This includes collaborative planning, decision-making, and co-design of research objectives, methods, and outcomes	[163, 273]
Indigenous research frameworks	Incorporating Indigenous research frameworks and methodologies that align with Indigenous worldviews, protocols, and knowledge systems. This ensures that research is conducted in a manner that respects and reflects Indigenous values and perspectives	[273]
Knowledge co-creation and sharing	Fostering knowledge co-creation and sharing by acknowledging and valuing the expertise and perspectives of Indigenous knowledge holders. This involves creating spaces for dialogue, active listening, and reciprocal learning, where both Indigenous and scientific knowledge systems can be mutually respected and integrated	[26, 46]
Community engagement and capacity building	Engaging with Indigenous communities in a respectful and ongoing manner, building trusting relationships, and promoting capacity building within the community. This includes providing opportunities for skill development, training, and knowledge exchange, empowering communities to conduct their research and advocate for their rights	[193]
Intellectual property rights and benefit sharing	Recognizing and respecting Indigenous intellectual property rights, including the right to control, own, and benefit from their knowledge. Researchers should ensure that any commercial or intellectual property outcomes resulting from the research are shared equitably and in consultation with the community	[225]
Ethical protocols and informed consent	Following rigorous ethical protocols and obtaining free, prior, and informed consent from Indigenous communities and individuals. Researchers should be aware of and adhere to relevant guidelines and protocols, respecting privacy, confidentiality, and cultural protocols regarding the use and dissemination of Indigenous knowledge	[273]
Long-term collaboration and reciprocity	Building long-term collaborative partnerships with Indigenous communities based on trust, reciprocity, and shared decision-making. Researchers should prioritize sustained engagement beyond the research project, supporting community-led initiatives, and contributing to the long-term well-being and self-determination of Indigenous communities	[26]

sation, attentive listening, and mutual education with Indigenous knowledge keepers. This method recognizes the complementary capabilities and insights of Indigenous and scientific knowledge systems. Researchers and Indigenous communities can better respect community procedures and preferences during the dissemination of research findings by encouraging knowledge co-creation and sharing [26, 46].

Collaborative strategies must always include community involvement and capacity building. Researchers maintain mutually beneficial connections with Indigenous people based on mutual respect and a commitment to capacity building. This includes facilitating research, rights advocacy, and decision-making by communities through providing opportunities for skill development, training, and knowledge exchange. Through community involvement, research is done with Indigenous communities rather than on them, and results are tailored to their needs and goals [273].

In the context of collaborative research, individual patent rights and benefit sharing are crucial factors to address. Researchers have an obligation to honor the rights of Indigenous people to the fruits of their intellectual labor. This involves making sure the community has a voice in and benefits from any financial or intellectual property decisions made as a consequence of the study. Financial compensation, capacity-building initiatives, and community-driven projects that improve the well-being and self-determination of Indigenous communities are all examples of the types of benefits that can be shared under benefit-sharing agreements [225].

Collaborative research with Indigenous populations must adhere strictly to ethical protocols, including informed consent. In order to conduct their studies ethically, researchers must first have the free, prior, and informed consent of Indigenous groups and individuals. This requires open discussion of the research's goals, methods, outcomes, and drawbacks. Researchers also have a responsibility to adhere to cultural norms and practices around the sharing and use of Indigenous knowledge. Respect for the rights, well-being, and self-determination of Indigenous communities is essential to ethical research [163].

Collaboration strategies rely heavily on long-term cooperation and mutual benefit. It is critical to establish mutually beneficial partnerships with Indigenous communities that can last for decades. These collaborations go beyond the scope of a single study and instead contribute to the long-term health and autonomy of Indigenous communities through sustained participation and backing for community-led initiatives. Researchers show their dedication to Indigenous knowledge, community goals, and producing research with lasting good consequences by working together over the long term [59].

Researchers may safeguard Indigenous knowledge as an essential element of human heritage by adopting these collaborative methods. These methods respect the rights and ambitions of Indigenous people while also fostering mutually beneficial partnerships, bolstering cultural resilience, and adding to the co-creation of knowledge.

11 Synergies Between Indigenous Knowledge and Modern Phytochemistry in Herbal Medicine

When it comes to the study and development of herbal medicine, indigenous knowledge and modern phytochemistry are two separate but complementary fields. What we mean when we talk about "indigenous knowledge" is the wisdom that has been passed down through Indigenous cultures from one generation to the next. Meaningful use of plants for therapeutic reasons, including their recognition, gathering, processing, and administration. In contrast, contemporary phytochemistry entails the systematic investigation of plant chemicals to determine their chemical make-up and their medicinal applications [64].

Indigenous wisdom and modern phytochemistry complement one another in several ways that advance our knowledge of and access to herbal medicine. For example, native American lore is a treasure trove of information on medicinal plants, including their identities, traits, and historical applications. This information can help direct current phytochemical studies by pinpointing plants with the most potential. The chemical constituents present in these plants can be validated and their potential therapeutic activities determined by modern phytochemistry [76]. For instance, the discovery of quinine, an effective antimalarial compound, was made possible by indigenous people's familiarity with the tree's bark used in treating malaria (*Cinchona* species).

Comparison of Modern Therapeutic Methods to Traditional Healing Methods: Traditional indigenous healing focuses on the whole person, taking into account the body, mind, and spirit. This comprehensive method is consistent with current ideas in integrative medicine, which aim to combine conventional and scientific methods. Researchers can pinpoint the bioactive compounds responsible for the therapeutic effects seen in traditional healing practices by combining Indigenous knowledge with modern phytochemistry [92]. For instance, artemisinin, a powerful antimalarial compound, was initially isolated from *Artemisia annua* due to its historical use in malaria treatment [291].

Indigenous peoples' knowledge of the interdependence of plants, their environments, and the healing properties they contain is invaluable for the conservation and sustainable use of medicinal plants. Insights like these help keep medicinal plants around for future generations by facilitating their responsible collection, cultivation, and preservation. Sustainable harvesting practices and conservation methods can be developed with the help of modern phytochemistry by identifying plant chemicals and understanding their ecological roles [255]. The identification of plant compounds with potential therapeutic applications is just one example of the positive impact of collaboration between Indigenous communities and scientists in the Amazon rainforest, which has also led to the promotion of sustainable use and conservation of the region's biodiversity [167].

The identification of promising lead chemicals for drug research is aided by indigenous peoples' knowledge. The bioactive components in traditional medicines that have been used for generations often have therapeutic effects. Insight into their methods of action, safety profiles, and prospective applications in modern medicine can be gained through the use of isolation and analysis techniques made possible by modern phytochemistry [83]. By pooling resources, this collaborative strategy can speed up the drug development process by drawing on Indigenous tribes' rich store of knowledge. For instance, indigenous peoples' use of the Pacific yew tree (*Taxus brevifolia*) resulted in the creation of paclitaxel, an effective cancer medicine [248].

Integrating traditional Indigenous knowledge with contemporary phytochemistry honors and celebrates Indigenous communities' rich cultural histories and valuable contributions. It encourages Indigenous communities' cultural maintenance, knowledge transmission, and self-determination through the participation of Indigenous knowledge holders in research and the acknowledgment of their expertise. By working together, we can guarantee Indigenous voices are heard and respected, which is essential to building cultural strength and autonomy [5]. Additionally, it strengthens the recognition and protection of Indigenous intellectual property rights, which helps with the fair distribution of profits made from selling herbal medicine items [75].

Indigenous wisdom and contemporary phytochemistry complement one another, creating a robust foundation for the development of herbal medicine. Researchers can learn more about medicinal plants' therapeutic potential by combining traditional wisdom with scientific rigor. Together, academics and Indigenous communities can ensure that Indigenous knowledge is respected, safeguarded, and used ethically, all while gaining from the experience.

12 Future Directions in Advancing Indigenous Phytochemistry Research

The integration of traditional and Western medicine, as well as the establishment of ethical research collaborations, are all necessary steps toward advancing indigenous phytochemistry research. Researchers may help preserve and advance indigenous cultures by embracing these future directions, which will also advance the scientific community's knowledge of the tremendous potential of molecules originating from plants. The combination of these two approaches has the potential to enhance healthcare, discover novel medications, and ensure the long-term survival of medicinal plants utilized by indigenous peoples. Indigenous phytochemistry research has the potential to make a significant effect in the future if it moves in a few key directions.

First, scientists and indigenous populations need to work together in an ethical manner to advance indigenous phytochemistry research [277]. Community involvement, informed consent, and fair distribution of benefits are all crucial to the success of such partnerships. To a large extent, phytochemical studies can benefit from indigenous peoples' extensive familiarity with local flora and traditional therapeutic practices [240]. Researchers can learn more and ensure that indigenous community's benefit from their studies if they treat indigenous people as equal collaborators [302].

Prioritizing the preservation and protection of indigenous knowledge is crucial to the success of indigenous phytochemistry studies. In order to preserve their cultural and medicinal expertise, traditional knowledge holders should be recognized as the principal custodians [272]. To avoid exploiting or appropriating holy practices, researchers should consult with elders and healers as they navigate the complexity of indigenous knowledge systems.

Third, using current analytical techniques Indigenous phytochemistry research stands to benefit much from the development of modern analytical methods. The identification and characterization of bioactive chemicals from traditional medicinal plants can be sped up by integrating technologies like liquid chromatography-mass spectrometry (LC-MS) and nuclear magnetic resonance (NMR) spectroscopy [39]. These methods can also be used to standardize herbal compositions, boosting confidence in their reliability [280] and usefulness.

The future of indigenous phytochemistry research should center on bridging Western and non-Western approaches to healthcare. Therapeutic benefits from combining plant chemicals with conventional medications may be further investigated through collaborative research. Integrating these two fields can also help researchers find ways to prove the value of traditional medicine through scientific inquiry.

13 Conclusion

As a result of the extensive historical observations, cultural transmission practices, and profound understanding of the medicinal properties of plants among the local population, collaboration between traditional expertise and indigenous knowledge of phytochemistry holds significant promise in advancing our understanding of the therapeutic effects of herbs. Traditional healing practices contribute to the foundation of Indigenous wisdom, which in turn provides valuable insights into plant medicinal properties. Also, combining rigorous scientific analysis of plant chemicals with insights from cultural traditions will improve researchers' ability to effectively identify, validate, and harness plant medicinal properties. It is important that herbal therapy research is based on solid evidence and takes into account cultural context and societal significance through collaborative efforts.

Furthermore, the occurrence of a synergistic relationship between traditional knowledge and indigenous phytochemistry helps to promote the preservation and sustainable use of medicinal plants. Thus, increasing public awareness and understanding of the ecological significance of medicinal plants plays an important role in the conservation of natural resources for future generations through the advancement of increased awareness, sustainable harvesting techniques, promotion of conservation effort, and avoidance of wasteful practices. Furthermore, the integration of traditional medicine and modern science will significantly advance drug research and discovery. This convergence provides an opportunity to create novel pharmaceuticals based on the invaluable wisdom of ancient Indigenous knowledge.

Abstract

The fields of business, sustainability, and herbal medicine are linked and continue to interact for the actual and potential benefits of all stakeholders. This chapter provides a comprehensive understanding of the interplay between herbal medicine, business, and sustainability by offering invaluable insights for scholars, practitioners, health policymakers, and industry and other stakeholders. The herbal medicine industry is at the crossroads of tradition and modernity. Therefore, an examination of the economic perspectives of herbal medicine from a sustainability viewpoint as well as the present evolving roles of herbal medicine in today's global market is critical. The current global landscape of Integrative and Complementary Medicine is driving the rise of a form of conventional medicine practice that is considered Traditional, Complementary, Alternative, and Integrative Medicine that encompasses a diverse range of medical and healthcare interventions, practices, products, and disciplines and has heightened the need for sustainability within the business of herbal medicine. For instance, bringing herbal cosmeceuticals to the global market as natural cosmetics presents unique challenges, especially in but also beyond developing nations. Manufacturers face hurdles in developing eco- and user-friendly cum value-added herbal products with sustainable attributes. Moreover, establishing new herbal products from indigenous medicinal practices requires bolstering Private-Public Partnerships in collaboration with universities, research institutes, private industries, and other key medical stakeholders. This chapter discusses the challenges, solutions, and business perspectives of key interactions that can improve the nexus of herbal medicine, business, and sustainability like eco-friendly packing, regenerative sourcing, community engagement, research on sustainable practices, transparent communication, consumer and medical stakeholder feedbacks, education and training, policy and partnerships, and the adoption of innovation. Finally, the chapter highlights the interconnectedness and feedback loop of the nexus as well as major stakeholder groups as well as their influence and interests.

1 Introduction

The importance of herbal medicine, in today's world cannot be overstated. It not only plays a role in promoting good health but also has a strong presence in the business sector [1–7]. When one delves into studies conducted on the herbal practice, products, and the dynamic world of international business, an interesting overlap becomes apparent. This yin-yan loop is a form of common or socio-economic and ecological collectivism that is currently without an institution-based paradigm [8–10]. The ancient practices of herbal medicine seamlessly merge with business methodologies creating a harmonious synergy. Adding to this blend is the concept of sustainability, which acts as a binding force fostering respect and reliance, between traditional and modern approaches. Together these three elements – herbal medicine, business, and sustainability – form a network of interconnectedness and shared influence.

Furthermore, herbal medicine has been a cornerstone of holistic health and wellness since its inception in ancient civilizations [11–22]. Its guiding principles, which are based on the harmonious coexistence of humans and nature, place a strong emphasis on the responsible use of natural resources. As a result, medicinal plants must be grown, harvested, and used in a way that preserves their potency and ensures their availability for years to come [23–25]. Herbal medicine has experienced global popularity, which is evidence of both its ongoing relevance and the growing appreciation of its capacity to address contemporary health issues.

Conversely, the realm of business, especially in the digital age, has witnessed transformative changes. The rise of e-commerce platforms, such as Alibaba and Zongteng, has revolutionized the way businesses operate, reaching global audiences and tapping into new markets [26–28]. These platforms leverage advanced technologies such as blockchain, to enhance supply chain efficiency, ensuring transparency and reliability in transactions. The integration of technology into business models has not only streamlined operations but has also opened avenues for sustainable business practices [29]. For instance, the establishment of overseas warehouses by cross-border e-commerce companies exemplifies supply chain innovations that prioritize localization, reducing carbon footprints, and promoting sustainable logistics.

Nevertheless, in the intricate landscape of today's global discourse, the prominence of sustainability cannot be emphasized enough [2]. This principle, much like the revered practices of herbal medicine, not only shapes our understanding of ecological balance but also carves a niche in the realm of modern business methodologies. As one navigates through the extensive research on global adversities, notably the profound impacts of climate change and the alarming erosion of biodiversity, a compelling narrative unfolds. This narrative accentuates the pressing demand for initiatives that are not only in harmony with nature but also economically pragmatic and socially just. Furthermore, venturing deeper into the vast expanse of the global economic tableau, particularly when reflecting upon the tumultuous waves created by unforeseen calamities such as the COVID-19 pandemic, the essence of sustainable business frameworks becomes even more palpable. E-commerce platforms, sensing the evolving pulse of consumer dynamics, have elegantly shifted their compass. Their strategies now resonate with a broader ethos, one that transcends mere fiscal achievements and embraces the ideals of environmental guardianship and societal enrichment.

The chapter aims to elucidate the nexus of business, sustainability, and herbal medicine from a multifaceted standpoint that includes an examination of the economic perspectives of herbal medicine, shedding light on its historical significance from a sustainability viewpoint and the present evolving role in today's global market. The chapter also provides a critical dissection of the current business focus of herbal medicine products and practices, offering insights into market trends, consumer preferences, and commercial strategies. Furthermore, the incorporation of sustainability into herbal medicine practices and products is interrogated. This objective seeks to determine the conceptualization of sustainability within the herbal medicine industry, probing its current manifestations and suggesting avenues for enhancement. The subsequent objective is to forecast the realm of sustainable herbal medicine business, presenting a prospective outlook that envisions a harmonious blend of economic prosperity, environmental stewardship, and holistic health. Additionally, the work ascertains the specific business needs of herbal medicine, pinpointing pivotal elements that can fortify the industry and ensure its continued growth and relevance. Finally, the prerequisites for sustainable herbal medicine products and practices are demarcated, outlining foundational requirements and best practices that can steer the domain toward a sustainable trajectory. In synthesizing these objectives, this chapter seeks to provide a comprehensive understanding of the interplay between herbal medicine, business, and sustainability, offering valuable insights for scholars, practitioners, policymakers, and industry and medical stakeholders.

2 Economic Perspective of Herbal Medicine

In the evolving landscape of healthcare and commerce, the economic implications of herbal medicine have garnered significant attention. Recent studies have sought to elucidate the potential economic benefits and challenges associated with the integration of herbal medicine into modern healthcare systems. Gautam et al. [30] highlighted the socio-economic importance of wild Ayurvedic medicinal plants in the Western Himalayas, emphasizing the potential economic upliftment of local communities through large-scale cultivation. This perspective is supported by Sharma et al. (2019), who noted the increasing global demand for Ayurvedic products and the potential for local communities to tap into this lucrative market. However, critics like Patel et al. (2020) argue that while there is economic potential, overharvesting and lack of sustainable practices could lead to the depletion of valuable resources and long-term economic losses. Aside from that, the review by Geng et al. [31] on Fagopyri Dibotryis Rhizoma (FDR) underscores its therapeutic and economic benefits, particularly its antitumor pharmacological activity. Zhang et al. (2021) concurred, noting the rising demand for natural antitumor agents in the global market. However, Wang et al. [32] caution that while FDR shows promise, over-reliance on a single herbal product could lead to market saturation and reduced economic returns. Nevertheless, Mehboob's [33] study on the use of Complementary and Alternative Medicine (CAM) in healthcare emphasizes the economic significance of herbal medicine as a subset of CAM. This observation is echoed by Lee et al. (2019), who noted the increasing global expenditure on CAM products. Contrarily, Thompson et al. (2021) argue that while CAM, including herbal medicine, is popular, it often leads to out-of-pocket expenses, potentially straining individual finances. Dewi et al.'s [34] research on the indirect costs faced by chronic kidney failure patients underscores the economic considerations of incorporating herbal treatments. This is in line with the findings of Kumar et al. [28], who noted the potential cost-saving benefits of herbal treatments in chronic diseases. However, critics like Singh et al. (2022) point out that while initial costs might be lower, the long-term efficacy and potential side effects of herbal treatments could lead to increased economic burdens in the future.

2.1 Economic Implications of the Herbal Medicine Industry

The economic implications of the herbal medicine industry are vast and multifaceted. With a significant portion of the global population relying on herbal remedies, the market potential is enormous. However, this burgeoning demand also brings forth challenges related to sustainable cultivation, fair trade practices, and equitable distribution of economic benefits, especially in regions rich in biodiversity but poor economically.

In regions like the Swat Valley in northwest Pakistan, many practice subsistence farming, supplementing their income by collecting and selling wild harvested plants for use in herbal medicine. The cultivation of medicinal and aromatic plants in such areas not only contributes to economic development but also plays a pivotal role in biodiversity conservation [35].

Note that regions like Aritar in East Sikkim (India) are rich in ethnomedicinal knowledge, with diverse tribal communities relying on traditional medicines for their health needs. However, the economic potential of this knowledge remains largely untapped due to various challenges, including lack of awareness, standardization, and market access. However, the economic benefits derived from the herbal medicine industry are not always equitably distributed. In many biodiverse regions, local communities may not receive their fair share of the profits. This disparity is often exacerbated by a lack of regulatory frameworks and the dominance of middlemen in the supply chain. Ethical trade practices are essential to ensure that the communities responsible for cultivating and harvesting these medicinal plants benefit economically [36–38]. Nevertheless, the shift toward environmentally friendly agricultural practices, such as the cultivation of floating rice in Vietnam, represents a sustainable approach to farming. Floating rice, a traditional method of rice cultivation, offers environmental, economic, and social benefits. However, promoting such practices in international markets requires understanding consumer preferences. For instance, UK consumers have shown a willingness to pay premiums for ethical attributes like fair trade but may not necessarily value other environmental attributes like CO_2 emission reduction [39]. Moreover, the commercial success of herbal medicinal products (HMP) hinges on their compliance with regulatory requirements pertaining to quality, safety, and efficacy. However, the standards and regulations governing HMPs vary across countries, posing challenges for manufacturers aiming to introduce standardized herbal products in the global market. A collaborative effort between regulatory bodies and international organizations like the World Health Organization (WHO) is imperative to establish harmonized regulations for HMPs.

The works of Malathi et al. (2019) supported the earlier work of Chawla et al. [40] on diabetes, a prevalent lifestyle disorder, that has seen a surge in the use of herbal remedies for its management and noted that the transition from traditional herbal treatments to evidence-based herbal drug development is fraught with challenges, especially in terms of standardization. The lack of universally accepted technical standards, coupled with the absence of comprehensive regulatory guidelines, hampers the development and commercialization of effective herbal treatments for diabetes [40]. In addition, the works of Sahoo and Manchikanti [41] further support that of Chawla et al. [40] in their study on the Indian herbal drug industry, a significant player in the global herbal medicine market, which faces unique challenges in the manufacturing and commercialization of herbal medicines. Divergent regulatory requirements, especially in terms of quality control and safety standards, impede the industry's growth. Moreover, the weak implementation of existing regulations further exacerbates the challenges faced by manufacturers [41]. Furthermore, the production of herbal cosmeceuticals, especially in developing countries, faces numerous challenges. While these products offer both cosmetic and therapeutic benefits, their development requires a nuanced understanding of indigenous medicinal knowledge. The commercialization of such products is often hindered by factors such as lack of awareness, standardization issues, and limited market access. Collaborative efforts between research institutions, indigenous practitioners, and the private sector can help overcome these challenges [42].

2.2 Current Business Focus of Herbal Medicine Products and Practices

The global resurgence of herbal medicine, deeply rooted in ancient traditions, has evolved into a significant business sector in contemporary times. One of the key objectives set for this chapter is to critically analyze the current business focus of herbal medicine products and practices, emphasizing the diverse types of herbal medicine practices and their respective business orientations. Pan et al. [43] underscores the global re-emergence of herbal medicines, noting that approximately 75% of the world's population relies on herbs for primary healthcare. This "herbal renaissance" signifies not only a return to ancient practices but also a testament to the efficacy of herbal remedies. The study further emphasizes the dual-edged sword of demand, where the increasing global appetite for herbs has led to the potential overexploitation of more than 53,000 species. However, after this study, several studies have attempted to classify herbal medicine practices into different categories some of which have been identified and discussed in the next section.

3 Types of Herbal Medicine Practices

3.1 Traditional Herbal Medicine Practices: Global Perspectives

Traditional herbal medicines, which form a major branch of global healthcare systems, have been practiced within various cultural contexts and are often utilized based on different traditions and beliefs. These medicines are most times passed down through generations and constitute the backbone of many communities' healthcare systems. They offer not only therapeutic benefits but also an opportunity to connect with various ancestral wisdom and cultural identity.

Several studies have highlighted the use of traditional herbal medicine around the world. Particularly, Kunwar et al. [44] conducted a study in Nepal, a country that is very rich in biodiversity as well as several ethnic groups. The researchers highlighted the role of medicinal herbs in traditional treatments and therapies. These practices, deeply embedded in the cultural fabric, have been sustained over centuries, reflecting the intricate relationship between the people and their natural environment. In addition, Devkota et al. [45] emphasized the significance of medicinal plants in traditional medicine systems across Nepal. The country, with its diverse ecosystems, hosts a plethora of medicinal plants used in various indigenous therapeutic practices. However, these practices and the associated knowledge are not always well-documented, leading to the potential loss of invaluable information. The study underscores the need for detailed documentation, conservation efforts, and research to strengthen these traditional systems [16, 17, 46].

Another dimension to consider is the socio-cultural context surrounding traditional practices. A study by Thapa et al. [47] delves into the traditional menstrual practices in far-western Nepal, revealing the deep-rooted beliefs and cultural norms that influence such practices. While this study primarily focuses on menstrual practices, it sheds light on the broader context of how traditions, beliefs, and societal norms shape health-related behaviors in the community.

Furthermore, Sriharini and Syafira [48] discuss the concept of community empowerment by leveraging local potential with cultural value. In the village of Rejowinangun, herbal medicine, a hereditary heritage, is optimized for marketing in the concept of a tourist village, thereby increasing its economic and cultural value in modern society. In a similar vein, China has been at the forefront of traditional herbal medicine research, with a significant contribution to global research productivity in this domain. A study by Musa et al. [49] provides an overview of traditional herbal medicine research, emphasizing the annual increase in research after 1990. The study also highlights that the topmost-ranked authors and funding agencies were predominantly from Asia, especially China [49]. Traditional Chinese medicine has demonstrated potential in addressing various health conditions. For instance, a study by Xu et al. [50] emphasizes the role of traditional Chinese herbal medicine in ameliorating hyperuricemia. The research underscores the potential of certain natural compounds in treating hyperuricemia based on experimental studies [50]. In addition, East Asia has been known for the use of herbal medicine as well, as traditional East Asian herbal medicine offers potential treatments for various conditions, including neurodegenerative diseases like Amyotrophic Lateral Sclerosis (ALS). A scoping review by Suh et al. [51] delves into the potential of East Asian herbal medicine in treating ALS, emphasizing the need for large-scale and rigorously designed clinical studies [51].

3.2 Integrative and Complementary Medicine

Modern healthcare systems across the globe are increasingly recognizing the value of traditional herbal practices, leading to their integration into contemporary medical frameworks. This integration, often termed Integrative and Complementary Medicine (ICM), seeks to combine the best of both traditional and modern therapeutic approaches to provide holistic patient care. The current global landscape of ICM is driving the rise of a form of practice that is considered Traditional, Complementary, Alternative, and Integrative Medicine (TCAIM). TCAIM encompasses a diverse range of medical and healthcare interventions, practices, products, or disciplines that are not typically considered part of conventional medicine. Despite the variability in safety and effectiveness evidence profiles inherent in TCAIM, its use is highly prevalent among patients worldwide. A bibliometric analysis by Ng [52] provides insights into the characteristics of research published in TCAIM journals, emphasizing the upward trend in the volume of publications since the 1940s, with a significant increase observed between the mid-2000s and mid-2010s [52]. In addition to the works of Ng [52], Kenu et al. [53] conducted a study in Ghana, they discovered that approximately 70% of the population relies on traditional, complementary, and integrative medicine (TCIM) practices for primary healthcare needs. Recognizing its significance, the Ministry of Health integrated TCIM into the mainstream healthcare delivery system in 2012. The study conducted at the

LEKMA hospital in Ghana further revealed that the general belief in the potency, perceived effectiveness, location, and availability of TCIM services are key determinants of the high preference for its usage [53].

The findings of Ng [52] justify the works of Nugraha et al. [54] who noted that the recent COVID-19 pandemic has seen a surge in interest in herbal medicine as potential complementary treatments. Nugraha et al. [54] discuss various herbal agents, including *Echinacea, Cinchona*, and *Curcuma*, considered for the treatment of COVID-19. The study provides insights into the pros and cons of utilizing herbal medicine during global health crises [54]. The integration of traditional and complementary medicine into mainstream healthcare necessitates effective interprofessional communication. Hunter et al. [55] emphasize the importance of respectful, culturally competent interprofessional communication and collaboration that mutually supports patients' care needs. The study underscores the need for educational initiatives that promote inclusive, culturally competent, interprofessional communication and collaboration between conventional and TCAIM healthcare practitioners [55].

3.3 Commercial Herbal Medicine Production

The globalization of herbal medicine has ushered in a new era of large-scale commercial production of herbal products. This transformation encompasses the cultivation, processing, and distribution of herbal medicines, catering to an ever-expanding global market. The commercialization of herbal products has been driven by increasing consumer demand for natural remedies, the perceived health benefits of herbal medicines, and the integration of traditional herbal practices into modern healthcare systems.

Bringing herbal cosmeceuticals to the global market as natural cosmetics presents unique challenges, especially in developing nations. Manufacturers face hurdles in developing eco-friendly and user-friendly value-added cosmeceutical products with medicinal attributes. In many developing countries, establishing new cosmeceuticals from indigenous medicine requires fostering Private-Public Partnerships (PPP) in collaboration with universities, research institutes, and private industries. However, challenges such as knowledge-sharing barriers, lack of trained personnel with entrepreneurial skills, regulatory barriers, unsustainable collection practices of medicinal plants, and quality control issues persist [42]. Furthermore, the growing demand for agricultural commodities, including medicinal herbs, necessitates an optimization of crop distribution. A study by Davis et al. (2017) highlighted that the current global distribution of crops neither maximizes production nor minimizes water use. By reshaping the global distribution of crops based on total water consumption, it's possible to achieve greater food production while reducing water use, without compromising crop diversity or requiring massive investments in modern technology. Aside from that, the application of bacteriophages, or phages, in food production and processing is an emerging trend. Phages are viruses that infect bacteria and have been explored for their potential to improve food safety.

The use of phage biocontrol in food production offers a novel approach to combat bacterial contaminants, ensuring the safety and quality of food products, including herbal preparations [56–58].

4 Business Focus in Herbal Medicine

4.1 Herbal Medicine Market Dynamics and Globalization

The globalization of herbal medicine has led to a myriad of opportunities and challenges. As traditional remedies find audiences in distant parts of the world, the business landscape of herbal medicine is undergoing significant transformation with a mix of both positive and negative consequences. The global market potential of herbal medicine has seen a significant shift in product development and marketing strategies. In countries like Indonesia, companies are at the forefront of developing herbal medicinal products that promise safer long-term effects. The introduction of new herbal products necessitates the formulation of effective marketing strategies, which often involve both internal and external analyses. This includes understanding competitors, gauging consumer considerations, and leveraging frameworks like PESTEL analysis, Porter's Five Forces analysis (i.e., threats from new entrants, threats from new substitutes, bargaining power of suppliers, bargaining power of buyers, and influence of competitive rivalry), and SWOT analysis. Kunwar et al. [44] emphasize the challenges presented by uncontrolled exploitation, especially in regions like Nepal where many medicinal plants face potential extinction. The unregulated harvesting of medicinal plants can lead to a decline in biodiversity and disrupt the ecological balance. This underscores the need for sustainable harvesting practices and conservation efforts to ensure the long-term viability of these valuable resources [44]. In addition, the last few decades have seen unprecedented economic volatility, altering the political dynamics and socio-cultural landscape globally. New markets, such as the BRIC nations (Brazil, Russia, India, and China), have emerged as strong economic powers. As multinational firms expand into these markets, they face cultural challenges. Understanding these cultural elements is critical for the success of global firms, especially in the herbal medicine sector, where cultural beliefs and practices play a significant role [59].

4.2 Therapeutic Benefits and Modern Drug Discovery: "-omics" Approaches in Herbal Medicine Research

The nexus between traditional herbal medicine and modern drug discovery is a burgeoning area of interest, offering a plethora of opportunities for the pharmaceutical industry. This intersection of age-old wisdom and cutting-edge science is paving the way for the development of innovative therapeutic solutions. Furthermore, Tran et al. [60] have delved deep into the realm of bioactive compounds present in antidiabetic plants. Their research emphasizes the potential of certain bioactive drugs isolated from these plants, which have shown more efficacy than conventional oral hypoglycemic agents. The study underscores the importance of understanding the intricate molecular structures and mechanisms of these compounds, which can lead to the development of more effective and safer therapeutic agents for diabetes management. In addition, natural products, derived from plants, animals, or microorganisms, have been recognized for their myriad health benefits. In developing countries, a staggering 80% of the population relies on traditional or folk medicines, primarily plant-based, for disease prevention and treatment. These traditional medicines, often perceived as more affordable and having fewer adverse effects than modern drugs, have piqued the interest of the pharmaceutical industry. The diverse biological properties of plant-derived secondary metabolites, such as their anti-inflammatory, antidiabetic, and antioxidant activities, present a goldmine of opportunities for drug discovery.

Aside from that, recent research has highlighted the role of gut dysbiosis in the pathogenesis of colorectal cancer (CRC). Herbal medicine, with its rich repository of natural bioactive products, has shown promise in improving microbiota composition, repairing the intestinal barrier, and reducing inflammation. These therapeutic effects can potentially prevent the onset and progression of CRC. The study underscores the importance of understanding the intricate interplay between gut microbiota and herbal compounds, which can lead to the development of effective preventive strategies against CRC [61, 62]. The advent of omics approaches, encompassing transcriptomics, proteomics, genomics, metabolomics, and microbiomics, has revolutionized herbal medicine research and studies. These approaches provide a comprehensive understanding of the molecular mechanisms and interaction networks underlying the therapeutic effects of herbal compounds. For instance, omics-based studies have shed light on the effects and mechanisms of Chinese herbal medicines in gastrointestinal cancers, offering novel insights into potential therapeutic strategies.

4.3 Some Challenges in Herbal Medicine Production

Herbal medicine, an ancient practice that harnesses the therapeutic properties of plants, has witnessed a resurgence in recent years. As the global demand for natural remedies grows, the herbal medicine industry has responded by introducing a plethora of products. The major herbal medicine products are, however, still facing various issues including the following (Fig. 1):

4.3.1 Standardization of Traditional Herbal Formulations and Microbial Quality

Traditional herbal formulations have been an integral part of various cultures for centuries, offering therapeutic solutions to a myriad of health issues. However, as these formulations gain traction in the global market, concerns regarding their microbial quality have emerged. In Divo City, Côte d'Ivoire, traditional herbal formulations are a staple in the local healthcare system. A study by Elisée et al.

Fig. 1 Some challenges in herbal medicine production

(2022) sought to assess the microbial quality of 30 liquid herbal remedies commonly consumed in the region. The findings were alarming, revealing significant levels of microbial contamination in these products. The contamination ranged from yeasts and molds to coliforms and fecal streptococci. Such high levels of contamination underscore the potential health risks associated with the consumption of these remedies.

Furthermore, Traditional Chinese Medicine (TCM), a principal form of herbal medicine, is composed of treatments using multiple herbs with complex chemical profiles. Due to a lack of understanding of its modality and a lack of standardization, there are significant challenges associated with regulating TCM's safety for practice and understanding its mechanisms of efficacy [63]. In addition, despite recent research by Kexiang et al. (2022) highlights the antitumor effects of Chinese herbal medicine compounds, making the therapeutic potential of herbal formulations not limited to general health, the microbial quality of these formulations remains a concern. Ensuring the safety and efficacy of these products is crucial, especially when they are used to treat life-threatening conditions like cancer.

4.3.2 Quality Control in Traditional Chinese Medicine

Ensuring reproducible quality, efficacy, and safety from herbal drugs remains a challenging task. Herbal medicines typically consist of many constituents whose presence and quantity may vary among different sources of materials. For instance, Traditional Chinese Medicine (TCM) is another domain where herbal formulations play a pivotal role. However, concerns about the safety and quality of Chinese medicinal drugs (CMD) have been raised. A study conducted at the TCM hospital Bad Kötzting implemented a quality control program to ensure the safe administration of TCM drugs. The study found that several samples showed contamination, emphasizing the need for rigorous quality control measures in the production and distribution of these drugs [64]. However, fingerprint analysis has emerged as a very useful technique to assess the quality of herbal drug materials and formulations for establishing standardized herbal products [65].

4.3.3 Regulatory Challenges and Standardization

One of the critical challenges in the business of herbal medicine is the lack of standardization and regulatory oversight. While herbal medicines have been used for millennia, their integration into modern healthcare requires rigorous testing, standardization, and quality control to ensure safety and efficacy.

4.3.4 Safety Concerns and Toxicity

The safety of herbal medicines, especially those containing minerals like Cinnabar, has been a topic of concern. However, modern scientific evaluations have shown that when properly prepared, such medicines can meet safety standards [66].

5 Global Perspective on Herbal Drug Development

Despite the significant increase in global interest in the investigation and development of new botanical products, only a few have been approved till now. Natural product medication development has significant technical and financial hurdles. Regulatory agencies like EMA (Europe), ICH and WHO (International/Global), AYUSH and DCGI (India), ANSM (France), MHRA (UK), FDA (U.S.A), NMPA (China), NAFDAC (Nigeria), and others work to bring these herbal drugs under a regulatory pipeline to ensure their safety and efficacy [11, 67, 68].

5.1 Major Herbal Medicine Products in the Global Market

Herbal medicine, rooted in ancient traditions, has experienced a renaissance in the modern era. As consumers globally become more health-conscious and inclined toward natural remedies, the global market has seen a surge in the demand for herbal products especially in Africa and Asia.

5.1.1 Traditional Herbal Formulations in Africa

In regions such as Divo City in Côte d'Ivoire, traditional herbal formulations are not just a part of the cultural heritage but are also widely consumed for their perceived health benefits. However, a study by Elisée et al. (2022) highlighted concerns regarding the microbial quality of these products. The research assessed the microbial contamination of 30 liquid herbal remedies and found significant contamination levels, emphasizing the urgent need for stringent quality control measures to ensure the safety of these products for consumers.

In addition, obesity, a global health concern, has seen a rise in the use of herbal products as potential remedies. In Egypt, regime herbal teas in the form of fine powder are commonly used as phytotherapy for weight management. A study aimed at evaluating the quality control of two commercial herbal tea products available in the Egyptian market revealed that these products matched the identity and purity of genuine monoherbs, suggesting their potential for further clinical trials [69].

In bustling cities like Kampala, Uganda, there has been a noticeable proliferation in the trade of herbal medicines, especially those targeting common ailments like diarrhea and cough. A study conducted by Walusansa et al. [70] highlighted the widespread consumption of traditional herbal formulations in the city. However, concerns regarding the microbial quality of these products have been raised. The study assessed the microbial contamination of 30 liquid herbal remedies and found significant contamination levels. This underscores the pressing need for stringent quality control measures to ensure the safety of these products for consumers. The findings also emphasize the importance of establishing and adhering to standardized production and storage practices to maintain the efficacy and safety of herbal medicines [70–75].

5.1.2 Chinese Herbal Medicines in the European Union

Chinese herbal medicines (CHMs) have gained significant traction in international markets, especially in the European Union (EU). However, the quality control of CHMs remains a challenge for their acceptance in the EU. A comprehensive review by Mei Wang et al. compared the quality requirements for CHMs in the EU and China. The study highlighted the key factors of quality control, including regulations, extracts, and products. The review also discussed the legal status of traditional Chinese medicine granules in the EU, providing insights into the challenges and opportunities for CHMs in the European market [32].

5.2 Innovative Herbal Products and Marketing Strategies

The global market potential of herbal medicine has led to the emergence of innovative herbal products. Ganeshfit Company, for instance, has delved into the development of anti-inflammatory herbal medicinal products. Recognizing the need for a robust marketing strategy for new products, the company conducted extensive research, integrating internal and external analyses, to formulate potential marketing strategies. The study underscored the importance of understanding market dynamics, consumer preferences, and the competitive landscape to ensure the successful launch and acceptance of new herbal products in the market. The global herbal medicine market is vast and diverse, offering a plethora of products catering to various health needs. As the demand for these products grows, ensuring their quality, safety, and efficacy becomes paramount. Rigorous research, stringent quality control measures, and effective marketing strategies are essential to navigate the challenges and harness the opportunities in this burgeoning industry.

5.3 Herbal Medicine Products Market Strategy in the Global Market

The global market for herbal medicine products has witnessed significant growth over the past few decades. As consumers become more health-conscious and seek natural alternatives to conventional medicine, the demand for herbal products has surged and companies have utilized various strategies to survive in the market.

In Indonesia, for instance, the global health awareness trend has led to the rise of new herbal medicinal product innovations. The Ganeshfit Company's Research and Development Team, for instance, has been at the forefront of developing anti-inflammatory herbal medicinal products. These products are touted to have safer long-term effects compared to their synthetic counterparts. To successfully introduce these new products to the market, the company has employed a comprehensive marketing strategy. This strategy encompasses both internal and external analyses, including competitor analysis, consumer considerations, and market dynamics. The company's approach underscores the importance of a well-researched and tailored marketing strategy in ensuring the successful launch and acceptance of new herbal products in the market [76]. The agricultural sector, particularly the micro-small-scale segment in the Sukoharjo Regency (Indonesia), dominates all other economic activities in the community. Herbal medicine stalls have been identified as a priority for development within this sector. The focus has been on product development strategies that align with market demand and offer competitive advantages. The strategy formulation process involves a combination of external analyses, such as PESTEL analysis and Porter's Five Forces analysis, and internal analyses, including SWOT and VRIO (i.e., a four-question framework focusing on value, rarity, imitability, and organization) analyses [77]. However, the pharmaceutical market, which encompasses herbal medicine products, operates predominantly under monopolistic competition. This market structure allows for the extensive use of marketing tools, innovation, research, branding, and more. Certain segments of the pharmaceutical market, however, function within different market structures, such as monopoly and oligopoly. The global pharmaceutical market's growth forecasts up to 2027 indicate varying market development factors across different periods. Notably, Indian, and Chinese companies have shown high activity in developing the global pharmaceutical market, emphasizing the importance of strategic approaches, business model adaptation, and significant R&D investments [78].

5.4 External Factors Influencing Herbal Medicine Products in the Global Market

The global market for herbal medicine products has witnessed a significant surge in demand over the past few decades. As consumers become more health-conscious and seek natural alternatives to conventional medicine, the herbal medicine industry has capitalized on this trend. However, several external factors greatly impact the potential distribution of these medicines, and they include (Fig. 2):

5.4.1 Global Trade Dynamics

The dynamics of global trade have a profound impact on the herbal medicine market. For instance, the trade war between the USA and China, two of the world's largest economies, has implications for the global distribution chain, international trade, and

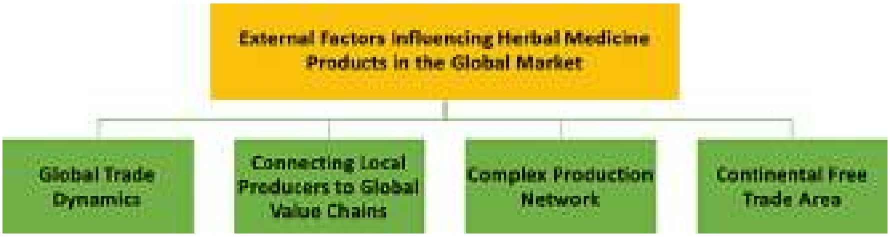

Fig. 2 External factors influencing herbal products in the global market

the economy at large. Such geopolitical events can influence the flow of herbal products between countries, affecting availability, pricing, and consumer choices [79].

5.4.2 Connecting Local Producers to Global Value Chains

The integration of local producers in developing countries into global value chains (GVCs) has been a focal point of discussion. While GVCs allow firms in developing countries to participate in international trade, the benefits of such participation are not automatic. Policies that build productive capacity, ensure inclusive growth, and upgrade capabilities are essential. The report by Bamber et al. [80] highlights the need for data and analysis to inform trade-related policy implications for developing countries, providing a foundation for discussions on domestic policies and actions required to promote beneficial participation in value chains.

5.4.3 An Increasingly Complex Production Network

Synonymous with the evolution of liquefied natural gas (LNG) in today's global market, the production network for herbal products is increasingly becoming more complex. While seemingly unrelated, the global market dynamics of (LNG) offer insights into the potential evolution of the herbal medicine market. Just as LNG has transitioned from a simple floating pipeline model to a more complex production network, the herbal medicine market is also transforming. The increasing demand for herbal products worldwide necessitates the development of robust supply chains, innovative distribution strategies, and adherence to international quality standards [81].

5.4.4 Continental Free Trade Area

The establishment of Continental Free Trade Areas (CFTAs) like the African Continental Free Trade Area (AfCFTA) creates enormous opportunities for the Herbal Medicine Industry (HMI) to tap into. For instance, the AfCFTA agreement, encompassing 55 nations and a combined GDP of $3.4 trillion, can potentially double intra-regional trade. For the herbal medicine sector, this means increased market access, collaborative research opportunities, and the potential for standardized production practices across member countries. The AfCFTA could also facilitate the sharing of traditional herbal knowledge, leading to the development of innovative products that cater to a global audience [82].

6 The Nexus of Business, Sustainability, and Herbal Medicine

The HMI stands at the crossroads of tradition and modernity. As the demand for natural remedies grows, so does the imperative need for a sustainable business approach. It is known that the fields of business, sustainability, and herbal medicine are linked and continue to interloop and interplay for the benefit of medical stakeholders. However, various issues and challenges continually impact and affect the nexus of herbal medicine, business, and sustainability, including some like the challenge of microbial contamination, toxicity, and standardization of herbal medicine products, which is tough to surmount. Aside from that, the economic implications of the HMI are profound, with vast opportunities for growth and innovation. There are still several challenges related to regulatory compliance, standardization, and sustainable production. To solve these challenges and bridge the gap between these fields it is important to incorporate the field of sustainability and business with herbal medicine as demonstrated in the proposed incorporation cycle in Fig. 3.

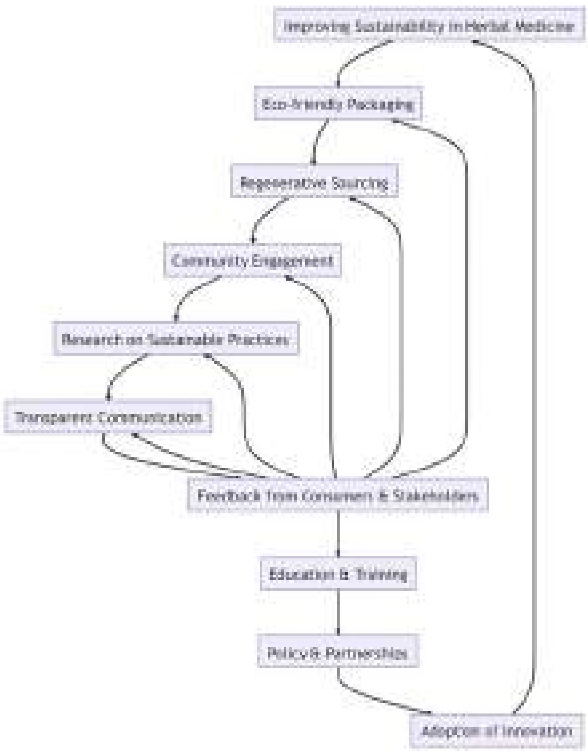

Fig. 3 Interactions within the nexus of herbal medicine, business, and sustainability

6.1 Eco-friendly Packaging

In improving sustainability and encouraging business growth the first step will be to provide eco-friendly packaging. This is because of the awareness of the majority of the population globally on the environmental issues with the indiscriminate use of plastics.

The global waste crisis is one of the most pressing environmental issues of our time. As urbanization and consumerism rise, so does the production of waste, particularly from packaging materials. A significant portion of this waste is non-biodegradable, meaning it doesn't break down naturally over time. Instead, it persists in the environment for hundreds, if not thousands, of years.

Traditional packaging solutions, often made from plastics and other synthetic materials, are a primary contributor to this crisis. These materials, once discarded, find their way into various ecosystems. Landfills overflow with waste, much of which seeps into the ground, contaminating soil and groundwater. Oceans are littered with plastic debris, leading to the formation of vast "plastic islands" that disrupt marine life. Wildlife, both marine and terrestrial, often mistake these materials for food, leading to ingestion, entanglement, and, in many cases, death. Furthermore, the production of traditional packaging materials is resource-intensive, often requiring significant amounts of water, energy, and raw materials. The carbon footprint associated with the production, transportation, and disposal of these materials further exacerbates global warming.

Eco-friendly packaging offers a beacon of hope in addressing the global waste crisis. At its core, eco-friendly packaging prioritizes the environment, both in terms of the materials used and the processes involved in its production, and typically involves:

- **Biodegradable Materials**: These are materials that can be broken down by natural processes, turning into water, carbon dioxide, and biomass. They decompose within a reasonably short time, leaving no trace behind. Examples include certain types of plant-based plastics and paper.
- **Recyclable Materials**: Packaging made from these materials can be processed and transformed into new products. This cycle can be repeated multiple times, reducing the need for raw materials and energy. Common recyclable materials include glass, aluminum, and certain types of plastics.
- **Reusable Materials**: Some packaging solutions are designed for multiple uses. Instead of being discarded after a single use, they can be cleaned and reused, significantly reducing waste. Examples include cloth bags, glass containers, and metal straws.

By adopting eco-friendly packaging, businesses can significantly reduce their environmental footprint. The reduced reliance on raw materials, coupled with decreased waste production, ensures that the environment is preserved for future generations. This does not only improve the environment (sustainability) but also plays a huge role in the business perspective as explained below.

In today's world, where information is at one's fingertips, consumers are more informed and conscious about their choices. Environmental concerns rank high on their list of priorities. Consumers are increasingly seeking out brands that reflect their values, and eco-friendly packaging is a clear indicator of a brand's commitment to sustainability. This may end up in one or more of the following:

- **Brand Differentiation**: In a saturated market, eco-friendly packaging offers brands a unique selling proposition. It sets them apart from competitors and appeals to a growing demographic of environmentally conscious consumers.
- **Increased Sales and Brand Loyalty**: Consumers are willing to pay a premium for products that are sustainably packaged. They are also more likely to remain loyal to brands that demonstrate a genuine commitment to the environment.
- **Cost Savings**: While the initial investment in eco-friendly packaging might be higher, the long-term benefits are manifold. Reduced waste management costs, decreased reliance on expensive raw materials, and potential tax benefits associated with sustainable practices can lead to significant cost savings.
- **Risk Mitigation**: With governments around the world implementing stricter environmental regulations, businesses that proactively adopt sustainable practices are better positioned to navigate these changes. They face fewer regulatory hurdles and are less likely to incur penalties.
- In summary, eco-friendly packaging is not just an environmental imperative but also a smart business strategy. It offers a win-win solution, benefiting both the planet and the bottom line.

Furthermore, after incorporating eco-friendly packaging into the herbal medicine industry, the authors of this chapter recommend the next step to include regenerating sourcing as this would further strengthen the corporate social responsibility of herbal medicine business owners as well as improve their brand value proposition which directly impacts the business and solves the challenges presented below.

6.2 Regenerative Sourcing

The global demand for herbal medicines has seen a meteoric rise in recent decades. This surge in demand, coupled with often short-sighted agricultural practices, has put immense pressure on the natural reserves of medicinal plants. Overharvesting, or the act of extracting more from the land than it can naturally replenish, has become a widespread issue. This not only depletes the immediate stock of valuable medicinal plants but also disrupts the natural balance of ecosystems.

Unsustainable agricultural practices further compound this problem. The excessive use of chemical fertilizers and pesticides, monocropping, and deforestation for agricultural expansion degrade the soil, reduce its fertility, and threaten local biodiversity [83]. The loss of biodiversity is particularly concerning as it reduces the resilience of ecosystems, making them more susceptible to diseases, pests, and climate change impacts.

Furthermore, the depletion of key medicinal plants jeopardizes the long-term availability of essential ingredients for the herbal medicine industry. This poses a significant threat to the health and well-being of countless individuals who rely on these medicines. Regenerative sourcing emerges as a beacon of hope in this challenging scenario. It goes beyond mere sustainability, aiming not just to maintain but to enhance and rejuvenate the health of ecosystems through one or more of the following:

- **Crop Rotation**: This age-old practice involves growing different types of crops in succession on the same land. Each crop type has different nutrient requirements and pest resistance. By rotating them, the soil's nutrient balance is maintained, and the build-up of pests and diseases is prevented.
- **Organic Farming**: Eschewing the use of synthetic fertilizers, pesticides, and genetically modified organisms, organic farming relies on natural processes and materials to cultivate crops. This ensures that the soil remains rich in organic matter and beneficial microorganisms, promoting long-term soil health.
- **Agroforestry**: This practice integrates trees, shrubs, and crops on the same plot of land. Trees and shrubs provide shade, reduce soil erosion, and enhance soil fertility through nitrogen fixation. They also act as windbreaks and improve water retention, creating a microclimate conducive to the growth of crops.

Together, these practices ensure that the land remains fertile and productive. They also enhance local biodiversity, ensuring that ecosystems are resilient and can support the sustainable harvesting of medicinal plants for generations to come. Hence, adopting regenerative sourcing practices offers a plethora of benefits from a business standpoint that include:

- **Long-term Supplier Relationships**: Consistent quality is paramount in the herbal medicine industry. By engaging in regenerative sourcing, businesses can foster long-term relationships with suppliers who adhere to these practices. This ensures a steady supply of high-quality ingredients.
- **Reduced Supply Chain Risks**: With the increasing global awareness of sustainability issues, there's a growing risk of resource scarcity. Regenerative sourcing mitigates this risk by ensuring the continuous availability of key ingredients.
- **Ethical Branding**: Modern consumers are well informed and value driven. They prefer brands that align with their ethical and environmental beliefs. By marketing products as ethically and sustainably sourced, brands can appeal to this growing demographic, enhancing their market share and brand loyalty.
- **Cost Efficiency**: While the initial transition to regenerative practices might require investment, the long-term benefits, such as reduced dependency on chemical inputs and enhanced soil fertility, can lead to cost savings.

Therefore, regenerative sourcing is not just an environmental and ethical imperative but also a strategic business decision. It ensures the long-term viability of the HMI while safeguarding the planet's precious biodiversity. Furthermore, after regenerating sources and ensuring the products are sourced through highly sustainable methods, the authors of this chapter recommend the next step to include community engagement as most of these herbal medicine as discussed in the previous sections hold some ties to certain cultural beliefs which have greatly been exploited. Community engagement will bring about more trust in the herbal medicine businesses.

6.3 Community Engagement

The rich tapestry of traditional knowledge, especially in indigenous regions, has been the backbone of herbal medicine for centuries. However, with the commercialization of herbal products and the race to source rare and potent ingredients, there's been a growing trend of exploitative sourcing. This often involves bypassing local communities, disregarding their rights, and harvesting resources without proper compensation or acknowledgment.

Such practices can lead to several adverse outcomes including:

- **Conflicts**: Disregarding the rights and wishes of local communities can lead to conflicts. These can range from disputes over land rights to disagreements about compensation and benefits.
- **Loss of Traditional Knowledge**: Exploitative sourcing often overlooks the wealth of knowledge that local communities possess. This knowledge passed down through generations can offer insights into the medicinal properties of plants, sustainable harvesting techniques, and more. Ignoring this can lead to the loss of invaluable information.
- **Socio-economic Disparities**: When businesses profit from resources without adequately compensating or involving local communities, it can exacerbate socio-economic disparities. While businesses thrive, the communities that have been stewards of these resources for generations may continue to face poverty and marginalization.

Community engagement emerges as a holistic solution to these challenges. It emphasizes the importance of building relationships, fostering trust, and collaborating with local communities through:

- **Respecting Traditional Knowledge**: Local communities, especially indigenous ones, have a deep understanding of their environment. By respecting and incorporating this knowledge, businesses can ensure that they are sourcing resources most effectively and sustainably.
- **Collaborative Partnerships**: Instead of a top-down approach, businesses can form collaborative partnerships with communities. This involves involving them in decision-making processes, from identifying resources to determining harvesting techniques and compensation structures.

- **Sustainable and Ethical Harvesting**: With the involvement of local communities, harvesting can be done in a manner that ensures the long-term viability of resources. This includes adhering to traditional harvesting calendars, using non-destructive methods, and ensuring that a portion of the benefits goes back to the community.

Engaging with communities is not just a moral obligation but also a strategic business decision with multiple benefits:

- **Positive Brand Image**: In an age of conscious consumerism, businesses that engage ethically with communities are viewed favorably. This can lead to increased brand loyalty, positive word-of-mouth, and a competitive edge in the market.
- **Unique Collaborations**: Trust-building at the grassroots level can pave the way for unique collaborations. This could involve joint research projects, knowledge-sharing initiatives, or access to rare resources that are not available through conventional channels.
- **Long-term Sustainability**: By making local community stakeholders in the business, companies ensure the long-term sustainability of their sourcing practices. Communities that benefit from the business are more likely to support and collaborate with it, ensuring a steady supply of resources.
- **Risk Mitigation**: Engaging with communities can help businesses pre-empt and address potential conflicts, reducing operational risks and ensuring smoother supply chains.

Therefore, community engagement offers a win-win approach. It ensures that businesses operate ethically and sustainably while also unlocking a plethora of opportunities for growth, collaboration, and innovation. Furthermore, it is recommended that after the process of community engagement, HMI practitioners delve into more research on sustainability as information obtained from community engagements can help improve sustainability practices.

6.4 Research on Sustainable Practices

Sustainability is not a static concept. As our understanding of the environment, ecosystems, and human impact evolves, so do the benchmarks for what is considered sustainable. The herbal medicine industry, like all sectors, faces the challenge of keeping pace with these changing dynamics through:

- **Evolving Standards**: What was considered sustainable a decade ago might not meet today's standards. As global awareness about environmental issues grows, industries are held to higher standards of sustainability.
- **Complex Ecosystem Interactions**: The interactions between various components of an ecosystem are intricate. A change in one component can have ripple

effects, making it crucial to have a holistic understanding before implementing any intervention.

- **Rapid Technological Advancements**: The pace of technological change is rapid. New technologies can offer more sustainable alternatives, but they also come with their own set of challenges and environmental impacts.

In the same way, research emerges as the cornerstone to address these challenges. It provides the knowledge and tools to navigate the complex landscape of sustainability such as:

- **Ecological Impact Studies**: Understanding the impact of farming practices, harvesting techniques, and production processes on the environment is crucial. Research can provide insights into the carbon footprint, water usage, soil health, and biodiversity impact of various practices.
- **Waste Reduction Innovations**: Waste, especially non-biodegradable waste, is a significant environmental concern. Research can explore innovative ways to reduce waste from developing biodegradable packaging to finding uses for production by-products.
- **Sustainable Farming Techniques**: Research can lead to the development of farming techniques that are both productive and sustainable. This includes exploring alternative pest control methods, soil conservation techniques, and sustainable irrigation practices.

From a business standpoint, investing in research is not just an environmental imperative but also a strategic business decision:

- **Innovation and Differentiation**: Research can lead to breakthrough innovations that set a brand apart. This could be a new sustainable farming technique, a novel product derived from waste, or a patented production process.
- **Brand Leadership**: Brands that are at the forefront of sustainability research are seen as industry leaders. This leadership position can translate into a strong brand image, customer trust, and a loyal customer base.
- **Economic Benefits**: Sustainable practices, derived from research, can lead to cost savings in the long run. For instance, reducing waste can lower disposal costs, and sustainable farming can reduce the dependency on expensive chemical inputs.
- **Premium Pricing**: Products that are backed by solid research and are verifiably sustainable can command premium prices in the market. Consumers are willing to pay a premium for products that align with their values.

Research on sustainable practices is a multifaceted endeavor that offers environmental, social, and economic benefits. For the herbal medicine industry, it ensures long-term viability, brand leadership, and a competitive edge in a market that is increasingly valuing sustainability. However, despite the need for research on sustainability, it is paramount that organizations encourage transparent communication based on research generated to inform all respective medical stakeholders.

6.5 Transparent Communication

The major challenge associated with non-transparent communication in the nexus of herbal medicine, business, and sustainability is greenwashing. Greenwashing is the practice of making misleading or unsubstantiated claims about the environmental benefits of a product, service, or company. In the Herbal Medicine Industry, this could manifest as exaggerated claims about organic sourcing, ethical practices, or environmental impact. The challenge here is significant because consumers are becoming increasingly savvy and skeptical. They demand authentic information and can easily spot inconsistencies or false claims, thanks to the plethora of information available online.

The solution includes:

- **Open and Honest Communication**: Transparent communication goes beyond merely sharing information; it's about creating an open dialogue with medical stakeholders, particularly consumers. This involves:
- **Full Disclosure**: Clearly stating the origins of raw materials, the methods of production, and the environmental impact of these processes.
- **Accountability**: Owning up to areas where the company may fall short of sustainability goals and outlining improvement plans.
- **Third-Party Verification**: Utilizing external audits or certifications to validate claims can add an extra layer of credibility.
- **Regular Updates**: Consistently update stakeholders on progress made toward sustainability goals, setbacks faced, and lessons learned.
- **Interactive Platforms**: Using social media, blogs, or dedicated sections on the company website where consumers can ask questions and receive prompt, honest answers.

In today's digital age, consumers are not just passive recipients of information; they are active participants in brand narratives. Transparency in communication can yield several business benefits:

- **Brand Loyalty**: Consumers are more likely to stick with brands that they trust. Transparency fosters this trust by showing that a company has nothing to hide.
- **Positive Reviews**: Satisfied, informed customers are more likely to leave positive reviews, which can significantly influence potential buyers.
- **Word-of-Mouth Marketing**: Transparency can turn consumers into brand advocates. People are more likely to recommend a brand that they feel is honest and aligned with their values.
- **Competitive Advantage**: In a market saturated with claims of 'natural' and 'sustainable,' genuine transparency can set a brand apart.
- **Risk Mitigation**: Being upfront about challenges and shortcomings can help mitigate the impact of any negative publicity and demonstrate a commitment to continuous improvement.

- **Stronger and Resilient Herbal Brands**: By embracing transparent communication, companies in the HMI can not only meet the growing consumer demand for sustainability but also build stronger, more resilient brands. In addition to this, seeking feedback can greatly improve sustainability practices.

6.6 Feedback from Consumers and Stakeholders

The challenge within this aspect of the nexus is linked to the imperfect nature of diverse sustainability models. Sustainability is a complex, multifaceted issue that requires ongoing efforts for improvement. No model or initiative is perfect out of the gate. The challenge lies in identifying the gaps, inefficiencies, or unintended consequences that may arise during the implementation of sustainability practices. This is particularly relevant in the Herbal Medicine Industry, where the stakes are high due to the involvement of natural resources, community welfare, and consumer health.

Actively seeking feedback from consumers and other medical stakeholders is crucial for continuous improvement. This can be achieved through:

- **Surveys and Questionnaires**: These can be sent to consumers post-purchase or be made available on the company's website.
- **Focus Groups**: Inviting a diverse set of stakeholders to discuss various aspects of the company's sustainability efforts can provide in-depth insights.
- **Public Forums**: Hosting webinars, Q&A sessions, or community meetings where stakeholders can voice their opinions and ask questions.
- **Social Media Engagement**: Utilizing platforms like Twitter, Instagram, and Facebook to gather feedback in real time.
- **Third-Party Audits**: External evaluations can offer an unbiased view of the effectiveness of sustainability initiatives.

To ensure there is a win-win business scenario, there needs to be an incorporation of feedback-driven sustainability approaches that offer several advantages including:

- **Product Improvement**: Consumer feedback can highlight areas where the product can be made more sustainable, whether it's the packaging, the sourcing, or the production process.
- **Process Efficiency**: Stakeholder feedback can help identify inefficiencies in the supply chain or production methods, leading to cost savings and a reduced environmental footprint.
- **Consumer Satisfaction**: Meeting or exceeding consumer expectations in terms of sustainability can lead to higher satisfaction rates, repeat purchases, and brand loyalty.
- **Regulatory Compliance**: Feedback from regulatory bodies can help the company stay ahead of legal requirements, reducing the risk of fines or sanctions.
- **Innovation**: Fresh perspectives from stakeholders can inspire new ways to approach sustainability, leading to innovative solutions that benefit both the company and the environment.

By incorporating feedback into their sustainability models, companies in the HMI can create a cycle of continuous improvement. This not only enhances their sustainability efforts but also builds a stronger, more competitive, and more resilient business. For these improvements to be implemented, education and training is highly paramount.

6.7 Education and Training

The challenge within this aspect of the nexus is linked to knowledge gaps, especially from a sustainability viewpoint. The adoption of sustainable practices is often hindered by a lack of knowledge and awareness. This is especially true in the Herbal Medicine Industry, where the supply chain involves various stakeholders, from farmers and suppliers to manufacturers and retailers. Without proper education and training, these stakeholders may inadvertently engage in practices that are detrimental to sustainability goals.

A potentially viable solution would be comprehensive education and training programs. Education and training are essential tools for bridging these knowledge gaps. The scope of these programs can be diverse, including but not limited to:

- **Workshops for Farmers**: Training on sustainable farming techniques, soil conservation, and responsible use of water resources.
- **Supplier Seminars**: Educating suppliers on the importance of ethical sourcing and providing them with the tools to achieve it.
- **Employee Training**: Regular training sessions for staff on waste management, energy conservation, and other sustainability practices relevant to their roles.
- **Stakeholder Webinars**: Online seminars that educate stakeholders on the company's sustainability initiatives and how they can contribute.
- **Public Awareness Campaigns**: Educational materials and campaigns aimed at consumers to inform them about the sustainability features of the products they are buying.

From the business perspective, there are numerous innumerable multifaceted benefits of education and training. Investing in education and training offers several business advantages:

- **Increased Efficiency**: An educated workforce is more likely to identify and implement efficient, sustainable practices, reducing waste and lowering costs.
- **Innovation**: Training can spark new ideas and approaches to sustainability, leading to innovative solutions that could give the company a competitive edge.
- **Regulatory Compliance**: Educated staff and suppliers are less likely to violate environmental laws and regulations, reducing the risk of legal repercussions.
- **Brand Image**: A company that invests in education is seen as responsible and committed to sustainability, enhancing its reputation among consumers and stakeholders alike.

- **Employee Satisfaction**: Employees take pride in working for a company that is committed to sustainability, leading to higher job satisfaction and lower turnover rates.

By prioritizing education and training, companies in the HMI can ensure that all stakeholders are aligned in their sustainability efforts. This not only accelerates the adoption of sustainable practices but also fosters a culture of continuous learning and improvement, benefiting both the environment and the business.

6.8 Policies and Partnerships

The challenge within this aspect of the nexus is linked to the limits of individual efforts. While individual companies may make significant strides in sustainability, the scale of environmental challenges often requires collective action. In the Herbal Medicine Industry, this is particularly relevant given the complex supply chains, diverse stakeholders, and global reach of many companies. Individual efforts, no matter how well intentioned, may fall short of creating the systemic change needed for true sustainability.

A potentially viable solution would be strategic collaborations and policy influence. To overcome this challenge, companies can engage in two main avenues:

- **Policy Advocacy**: Collaborating with governmental bodies to influence policies that promote sustainability. This could involve lobbying for stricter regulations on pesticide use, advocating for fair trade, or pushing for tax incentives for sustainable practices.
- **Partnerships**: Forming alliances with NGOs, academic institutions, and even competitors to amplify the impact of sustainability initiatives. These partnerships can focus on research, community outreach, or joint ventures that promote sustainability.
- **Certification Programs**: Partnering with organizations that offer sustainability certifications can add credibility to a company's efforts and attract a more conscious consumer base.
- **Public-Private Partnerships**: Engaging in collaborations that bring together the public and private sectors can leverage the strengths of both to achieve more significant results.

From the business perspective, there are multiple avenues to reap benefits from partnerships and policies. Engaging in policy advocacy and partnerships offers several advantages:

- **Financial Support**: Collaborations can often unlock access to grants, subsidies, or low-interest loans aimed at promoting sustainability, making it more financially feasible to undertake significant initiatives.

- **Policy Influence**: Being part of a larger coalition gives companies a stronger voice in policy discussions, allowing them to steer public policy in a direction that aligns with their sustainability goals.
- **Brand Enhancement**: Partnerships with reputable organizations can significantly boost a brand's image, positioning it as a leader in sustainability and attracting a more conscious consumer base.
- **Knowledge Sharing**: Collaborations often involve an exchange of expertise and resources, leading to more effective and innovative sustainability solutions.
- **Risk Mitigation**: Aligning with industry standards and governmental policies reduces the risk of non-compliance and the associated legal repercussions.

By actively engaging in policy advocacy and forming strategic partnerships, companies in the HMI can significantly amplify the impact of their sustainability efforts. This not only benefits the environment but also creates a more resilient and competitive business landscape.

6.9 Adoption of Innovation

The challenge within this aspect of the nexus is linked to the double-edged sword nature of technological innovations and evolution. The rapid pace of technological advancements offers a wealth of opportunities for enhancing sustainability. However, it also presents challenges in terms of adaptability, cost, and effective implementation. In the Herbal Medicine Industry, where traditional practices often coexist with modern methods, the integration of new technologies can be particularly complex.

A potentially viable solution would be the strategic adoption of innovative technologies. To harness the power of innovation for sustainability, companies can focus on:

- **Research and Development (R &D)**: Investing in R&D to explore new technologies that can make farming, production, and distribution more sustainable.
- **Pilot Programs**: Before full-scale implementation, running pilot programs can help assess the effectiveness and ROI of new technologies.
- **Technology Partnerships**: Collaborating with tech companies or start-ups that specialize in sustainable solutions can accelerate the adoption of new technologies.
- **Employee Training**: Ensuring that staff are well equipped to operate new technologies can maximize their effectiveness and sustainability impact.
- **Consumer Education**: Educating consumers about the benefits of new technologies, such as blockchain for traceability, can drive demand and acceptance.

From a business perspective, the strategic adoption of innovative technologies offers multiple advantages:

- **Operational Efficiency**: Technologies like the adoption of innovation can optimize various aspects of the business, from supply chain logistics to inventory management, leading to reduced waste and lower costs.

- **Cost Savings**: While the initial investment may be high, the long-term savings from reduced resource consumption can be significant. For example, adopting renewable energy sources can lower utility bills.
- **Competitive Edge**: Being an early adopter of sustainable technologies can position a company as a leader in the industry, attracting both consumer attention and potential partnerships.
- **Environmental Impact**: Technologies focused on waste reduction, energy efficiency, or sustainable sourcing have a direct positive impact on the environment.
- **Regulatory Advantage**: Staying ahead of the curve in terms of sustainable technologies can also mean staying ahead of regulatory changes, reducing the risk of non-compliance.

By being open to change and willing to invest in innovative technologies, companies in the HMI can significantly enhance their sustainability efforts. This not only benefits the environment but also translates into operational efficiencies, cost savings, and a stronger competitive position.

7 The Interconnectedness and Feedback Loop: A Holistic Approach to Sustainability

The model's strength lies in its design as a feedback loop, which underscores the interconnectedness of its various components. This loop is not just a theoretical construct but a practical tool for continuous improvement and alignment with broader sustainability goals.

7.1 Feedback from Consumers and Stakeholders

This is the cornerstone of the loop. Consumer and stakeholder feedback informs every other component, acting as both a catalyst and a checkpoint. For example, if consumers express concerns about packaging waste, this feedback can trigger changes in transparent communication to address these concerns. Similarly, this feedback can influence policy and partnerships, ensuring that any lobbying or advocacy efforts align with public sentiment.

7.2 Feedback from Education and Training to Policy and Partnerships

Education and training serve as the foundation for informed policy decisions. A well-educated workforce and stakeholder community are more likely to support and contribute to effective policies. This educated base can also be a powerful ally in advocacy efforts, lending credibility and weight to Policy and partnerships.

7.3 Feedback from Policy and Partnerships to Adoption of Innovation

Effective policies create a fertile ground for innovation. For instance, a policy that offers tax incentives for renewable energy can encourage companies to invest in new, sustainable technologies. These policies can also facilitate partnerships with tech companies, expediting the Adoption of Innovation.

7.4 Feedback from Adoption of Innovation to Improving Sustainability

The technologies and practices adopted feed directly into improving sustainability across the board. Whether it's a new waste reduction technology or a renewable energy source, these innovations contribute to the overall sustainability goals of the company.

7.5 Completing the Loop

The loop comes full circle with these innovations feeding back into the system, leading to further improvements. This could manifest as updates to existing policies, new training programs, or even shifts in consumer behavior due to more effective Transparent Communication. In essence, the feedback loop creates a self-sustaining cycle of continuous improvement. Each component not only contributes to sustainability but also informs and enhances the other components, creating a holistic, adaptable, and effective sustainability model with consideration of the business practices in the herbal medicine industry. However, to encourage implementation, this chapter examined the key stakeholders their roles and their impacts on this implementation.

8 Stakeholder Groups in the Herbal Medicine Industry

This chapter further delves into each stakeholder group to understand their roles, interests, and potential impact on sustainability initiatives in the HMI.

8.1 High Influence, High Interest

This quadrant is crucial for immediate action and long-term strategy. These stakeholders have both the interest and the power to drive or hinder sustainability initiatives. Regular engagement, transparent communication, and active involvement in decision-making processes are essential for maintaining a positive relationship with this group (Fig. 4).

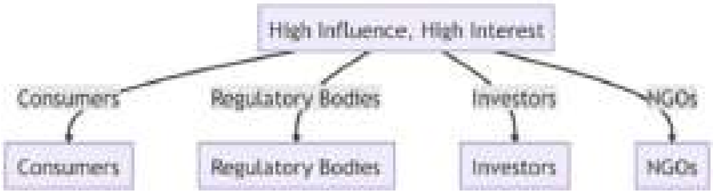

Fig. 4 High influence, high interest decision-making processes for maintaining a positive relationship within the nexus of business, herbal medicine, and sustainability

Consumers

I. **Role**: End-users of herbal medicine products.
II. **Interest**: Concerned about the quality, safety, and environmental impact of the products they consume.
III. **Impact**: Their purchasing decisions can significantly influence a company's sustainability practices. Brands that fail to meet consumer expectations risk losing market share.

Regulatory Bodies

I. **Role**: Organizations that set and enforce standards and regulations.
II. **Interest**: Ensuring that the industry operates within legal and ethical boundaries, including sustainability.
III. **Impact**: Can impose fines, sanctions, or even shut down operations for non-compliance, making their influence substantial.

Investors

I. **Role**: Individuals or organizations that provide capital.
II. **Interest**: Maximizing ROI while aligning investments with ethical and sustainable practices.
III. **Impact**: Can provide the necessary funding for sustainability initiatives or withdraw support if a company fails to meet sustainability criteria.

Non-governmental Organizations (NGOs)

I. **Role**: Non-profit organizations focused on various causes, including environmental sustainability.
II. **Interest**: Ensuring that the industry adopts sustainable and ethical practices.
III. **Impact**: Can mobilize public opinion and drive campaigns that force companies to adopt sustainable practices.

8.2 Low Influence, High Interest

While these stakeholders may not have the direct power to enforce changes, their high level of interest makes them valuable allies. They can offer insights, data, and public support, which can indirectly influence more powerful stakeholders. Periodic updates and collaborative projects can help keep this group engaged. The low

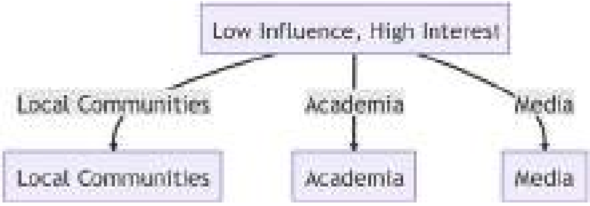

Fig. 5 Low influence, high interest decision-making processes for maintaining a positive relationship within the nexus of business, herbal medicine, and sustainability

influence, high interest decision-making processes for maintaining a positive relationship within the nexus of business, herbal medicine, and sustainability are presented in Fig. 5.

Local Communities

I. **Role**: Communities living in areas where herbal plants are sourced.
II. **Interest**: Sustainable and ethical sourcing, community development.
III. **Impact**: While they may lack formal influence, their cooperation is crucial for sustainable sourcing and long-term business operations.

Academia

I. **Role**: Educational institutions and researchers.
II. **Interest**: Researching and promoting sustainable practices.
III. **Impact**: Can provide valuable insights and data but generally lack the power to enforce change.

Media

I. **Role**: Channels of mass communication.
II. **Interest**: Reporting on industry trends, including sustainability efforts.
III. **Impact**: Can shape public opinion but cannot enforce regulatory changes.

8.3 High Influence, Low Interest

This group has the power to make or break sustainability initiatives but may not have a vested interest in them. The key is to make them see the value – whether it's financial, reputational, or regulatory – in participating in sustainability efforts. Tailored communication that speaks to their specific interests can be effective here. The high influence, low interest decision-making processes for maintaining a positive relationship within the nexus of business, herbal medicine, and sustainability are presented in Fig. 6.

Suppliers

I. **Role**: Provide raw materials for herbal medicine products.
II. **Interest**: Business continuity and profitability.

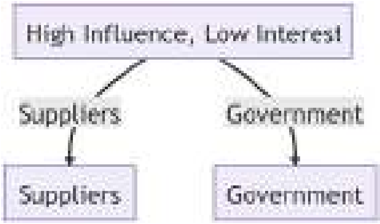

Fig. 6 High influence, low interest decision-making processes for maintaining a positive relationship within the nexus of business, herbal medicine, and sustainability

III. **Impact**: Have the power to choose sustainable sourcing methods, although they may not have a vested interest in sustainability.

Government

I. **Role**: State and federal governing bodies.
II. **Interest**: Economic growth, public safety.
III. **Impact**: Can enact laws that mandate sustainable practices but may prioritize other interests like economic development.

8.4 Low Influence, Low Interest

These stakeholders may seem less relevant due to their low influence and interest, but they can't be ignored. Changes in public opinion can gradually move them to a quadrant of higher interest or influence. Occasional updates and public awareness campaigns can be beneficial for this group. The low influence, low interest decision-making processes for maintaining a positive relationship within the nexus of business, herbal medicine, and sustainability are presented in Fig. 7.

Competitors

I. **Role**: Other companies in the herbal medicine industry.
II. **Interest**: Market share and profitability.
III. **Impact**: May adopt similar sustainability practices to stay competitive but have limited influence on other companies.

General Public

I. **Role**: The broader population is not directly involved in the industry.
II. **Interest**: General well-being and environmental sustainability.
III. **Impact**: Limited direct influence but can sway public opinion, which indirectly affects the industry.

Understanding the unique roles and interests of each stakeholder group can help tailor sustainability initiatives and communication strategies, ensuring a more effective and comprehensive approach.

It is important to note that by understanding the dynamics of each quadrant, herbal medicine businesses can tailor their sustainability strategies and

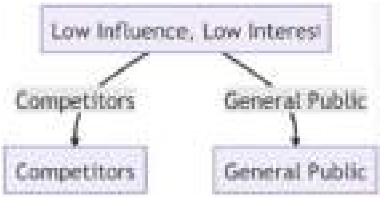

Fig. 7 Low influence, low interest decision-making processes for maintaining a positive relationship within the nexus of business, herbal medicine, and sustainability

communication plans to effectively engage each stakeholder group. This nuanced approach will likely yield better results in incorporating sustainability into the HMI with the business ethos in mind.

9 Conclusion

Sustainability in the HMI is not a one-off effort but a continuous process that involves multiple stakeholders, from farmers and local communities to policymakers within the healthcare sector and consumers. The comprehensive model presented in this chapter offers a multifaceted approach to sustainability, emphasizing the need for a holistic strategy that addresses various challenges and opportunities. By understanding and implementing each component of the model proposed in this chapter, the HMI can make significant strides toward a more sustainable future. While the economic potential of herbal medicine is evident, it is essential to approach the topic with a balanced perspective. The integration of herbal medicine into modern healthcare and commerce presents both opportunities and challenges. Sustainable practices, evidence-based approaches, and a focus on long-term benefits will be crucial in harnessing the full economic potential of herbal medicine. In addition, the herbal medicine industry, with its vast economic potential, presents both opportunities and challenges. Sustainable cultivation, fair trade practices, and equitable economic distribution are crucial to harnessing this potential. As the global demand for herbal remedies continues to grow, it is imperative to address these challenges to ensure the long-term viability and sustainability of the industry.

It is notable that traditional herbal medicine practices is deeply rooted in history and culture, but remains dynamic and continue to evolve in response to changing societal needs and global influences. As these practices navigate the challenges of modernity, it is crucial to ensure their preservation, documentation, and sustainable utilization, ensuring that future generations can benefit from this rich heritage. Nonetheless, the integration of traditional herbal practices into modern healthcare systems signifies a paradigm shift toward holistic patient care and a more robust healthcare system. While the potential benefits of Integrative and Complementary Medicine are evident, it is crucial to approach its implementation with a balance of respect for tradition, scientific rigor, and interprofessional collaboration. The commercial production of herbal products is a multifaceted endeavor, influenced by global trends, technological advancements, and consumer preferences. As the demand for herbal products continues to grow, it is imperative to address the challenges faced by the industry, ensuring sustainable practices, product quality, and safety. The globalization of herbal medicine presents a complex interplay of opportunities and challenges. While it offers a broader market reach and potential for growth, it also brings to the forefront issues related to sustainability, cultural sensitivity, and market dynamics. As the herbal medicine industry continues to evolve, businesses must adapt and innovate to navigate the global landscape effectively. The confluence of traditional herbal medicine and modern drug discovery is reshaping the therapeutic landscape. As research continues to unravel the mysteries of herbal compounds, there is immense potential for the development of novel drugs that are both effective and safe. The business focus in this domain promises lucrative opportunities, driven by scientific innovation and consumer demand for natural remedies. At the moment, the global demand for traditional herbal formulations is undeniable and will clearly grow in the future. However, as these new and old herbal products find their way into global markets, ensuring their microbial quality, safety, standardization, for standardization, quality control, innovative distribution strategies sustainability and alignment with global value chains and pricing regimes will be becomes paramount. Rigorous quality control measures, standardization, and continuous research are essential to guarantee the safety and efficacy of these age-old remedies. In the same way, the vast and diverse global herbal medicine market will continually need to evolve. As the demand for these products grows, understanding their distribution channels, market dynamics, and economic implications becomes paramount. Strategic approaches, informed by rigorous research and market analyses, are essential for navigating the challenges and harnessing the opportunities in this burgeoning industry. The nexus of business, herbal medicine, and sustainability has an immense growth potential but is faced with numerous pressing needs constantly emerging from their interaction. Hence, the need for the HMI to remain adaptive to global trade dynamics and geopolitical events to ensure sustained growth and consumer trust.

Abstract

The potential for nature-based healing pathways to promote physical, mental, and emotional repair has received a lot of attention. Tourists have a closer connection to nature and the restorative advantages of medicinal flora by adding medicinal plant walks into recreational development. This chapter discusses the development of healing trails as a revolutionary ecotherapy technique and continues to study its many features. Incorporating cultural history and traditional medical knowledge along these pathways strengthens communities' relationships with their natural environments. Healing trials that combine indigenous medicinal approaches not only help to preserve historical knowledge but also promote responsible plant usage and conservation. As more urban green spaces and parks are added, the positive impact on the well-being of city dwellers becomes more obvious. Furthermore, research into the combining of medicinal plant walks with other healing techniques provides a promising path toward a holistic approach to health. However, keeping historical relics secure, welcoming all people, and adhering to ethical foraging techniques provide challenges and concerns along these roads. Implementing high-quality certification programs is critical for tackling these difficulties. This protects the integrity of healing paths, prioritizes trail user safety, and defends fragile habitats. The chapter concludes with a suggestion to use universal design principles to construct healing paths that are accessible to persons with impairments and from varied cultural backgrounds.

1 Introduction

Since ancient times, people have understood that spending time in nature can have positive effects on their health, and this understanding has only grown in recent decades. Healing trails or medicinal plant walks have been practiced for millennia as part of several traditional therapeutic modalities, thus the idea is not new. Medicinal plant walks have been an integral part of many healthcare systems [1–5], including those that place a high value on local flora (such as indigenous healing practices) and those with complex materia medica (such as Traditional Chinese Medicine and Ayurveda) [6–9]. Practitioners can draw on a wealth of traditional knowledge by merging these tried-and-true methods into modern alternative medicine, all the while taking into account the latest in scientific findings and safety concerns.

Healing Trails are an innovative and comprehensive way to improving human health and fostering environmental protection by incorporating medicinal plant walks into recreational projects [10]. Physical exertion, mental de-stressing, and the opportunity to learn about the medicinal plants that grow wild on Healing Trails make for a potent therapeutic experience. Consequently, a growing number of people in today's culture are leaving the bustle of city life to find peace and rejuvenation in the great outdoors. Ecotherapy, often known as green therapy or nature-based healing, is a relatively new field that investigates the psychological and physiological advantages of relaxing in natural settings. Interest in incorporating environment-based experiences into numerous areas of life, particularly recreational development, has been prompted by the expanding body of studies supporting the good beneficial effects of nature on human health.

The mental and physiological advantages offered by spending time in nature have been well-documented. For instance, studies by Astell-Burt et al. [11], Jacob et al. [12, 13], and Udoakpan et al. [14] indicated that time spent in green spaces including parks, forests, and gardens alleviated symptoms of anxiety, depression, and stress-related disorders. Trees, water, and vegetation have been shown to have a healing impact on the mind, boosting one's disposition and ability to concentrate [15].

The biophilia theory, put out by E. O. Wilson, states that people have an inbuilt connection to nature and that our well-being is profoundly influenced by how we engage with the environment [16]. This idea of healing in nature is consistent with this notion. As cities expand into more and more green areas, residents are looking for ways to reduce the stress of city life by spending time in nature.

Changing our perspectives on public spaces may be as simple as incorporating nature-based therapy into recreational development. Recreational areas can be made into safe havens of good health and recuperation by including natural components like parks, landscaped areas, and healing paths with medicinal plant walks [12, 17]. This new emphasis places greater weight on the design of spaces that encourage interactions between people and the natural world, acknowledging the therapeutic potential of nature.

Also, with the growing awareness of the value of green spaces in boosting the general quality of life as urbanization continues to increase, people have become more alienated from natural areas. In response to the stresses of city life, healing trails have emerged as a way to help people relax, de-stress, and recharge in natural settings without having to go too far from their homes [18]. Thus, the popularity of healing trails has increased and more people now look for natural and holistic ways to improve their health. This network of paths provides an excellent opportunity to learn about the intricate web of connections between human well-being and the natural world.

Therefore, within the context of conventional medicine, historical preservation, and city landscaping, this chapter delves into the many facets of healing trails. We explore into the healing trails' potential to alleviate stress, anxiety, and despair while encouraging a profound bond with the natural world. We also discuss the value of indigenous healing methods, long-term economic growth, and the improvement of certain health ailments thanks to these natural havens. Inclusion, responsible foraging, and proper plant identification are all stressed. The need for quality standards and certification systems to guarantee healing trails' veracity and visitors' safety is also addressed. It also highlights the rich potential of healing trails as transforming spaces that nourish well-being through the embrace of nature's healing embrace and highlights the importance of evidence-based design, cultural integration, and accessibility.

2 Recreational Development and the Roles of Medicinal Plants

This section delves into the concept of recreational development, components, and the significance of Healing Trails in protecting indigenous medicinal plant knowledge. This facet of Healing Trails emphasizes the significance of recognizing and adapting indigenous healing practices into contemporary recreational development. Different indigenous groups have amassed extensive knowledge of the local ecosystems over time, including the medicinal benefits of local flora. By incorporating this understanding into recovery Trails, we can encourage the preservation of cultural history while simultaneously providing tourists with a one-of-a-kind and holistic approach to recovery.

2.1 Concept of Recreational Development

Recreational development is an essential part of city and neighborhood planning which includes the design, construction, and maintenance of facilities and programs for amusement, relaxation, and exercise [19]. Its value resides in its capacity to promote community prosperity, harmony, and long-term growth [20, 21].

The establishment of public areas like parks, playgrounds, and sports fields is an essential part of recreational development. All sorts of activities, from sports and physical exercise to relaxing and socializing, rely on these places as their primary locations. Particularly parks have been acknowledged for their beneficial effects on physical health, stress reduction, and providing a respite from city life [22]. In addition, recreational places that are planned correctly can motivate people to be more physically active, which aids in the fight against obesity and cardiovascular disease [23].

Cultural and entertainment amenities also fall under the umbrella of recreational development. The cultural fabric of a community benefits greatly from the establishment of performance venues, educational institutions, and social hubs such as museums, art galleries, and community centers. These places help people feel like they have a place in the community and give them something to be proud of [24].

Recreational planning in the modern era relies heavily on sustainable development principles. Studies have found that spending time in natural settings, especially green spaces, can improve one's mental health and well-being by providing a welcome break from the stresses of city life [25]. Sustainable features, such as energy-efficient lighting, water conservation measures, and the use of recycled materials, contribute to environmental stewardship and improve the ecological balance of communities when included into recreational areas.

Community involvement and input are essential to the success of any recreational development project. When planning and developing parks and other recreational areas, it is essential to get feedback from local residents, stakeholders, and user groups. Involving the locals in the planning process helps make sure the ultimate result is suitable for the people who will be using it. The incorporation of recreational development into urban and community planning is essential to the promotion of health, social integration, and long-term prosperity. Communities may improve their residents' physical and mental well-being as well as cultural and environmental sustainability by investing in the development of a wide range of recreational places and services. Recreational infrastructure helps build strong, diverse communities via participation and cooperation.

2.2 Concept and Components of Healing Trails

Healing trails, also known as therapeutic or nature trails, are a type of outdoor recreational development with the goal of fostering psychological, physiological, and spiritual health in its users [26, 27]. These trails are an upgrade from the standard hiking route since they include amenities designed to stimulate the senses, calm the mind, and bring you closer to nature [28, 29]. To promote healing, stress reduction, and general well-being, healing paths are constructed with careful planning and design.

The idea behind healing trails stems from research showing the health benefits of spending time in nature. The notion was inspired by the Japanese tradition of forest healing, also known as "Shinrin-yoku" or "forest bathing." This method entails spending time in nature and interacting with it consciously in order to improve one's health and well-being [26].

Consequently, the integration of nature-based healing practices into the planning, design, and management of public areas, healing trails serve a novel and game-changing concept in recreational development. The desire for environments that promote psychological, emotional, and physical health has led to the development of healing trails in response to the rising popularity of nature-based healing. Careful planning has gone into including picturesque spots and areas rich in biodiversity along these paths, giving hikers opportunities for more than just passive enjoyment. The addition of therapeutic plant walks to these pathways gives visitors a new option to connect with nature and learn about the plants' healing capabilities.

The components of healing trails as indicated in Table 1 include the following:

(i) **Design for Accessibility and Inclusivity:** Accessibility and inclusivity are key considerations in the construction of healing trails. This is to ensure that people of all ages and abilities may take part in the therapeutic experience. Paths are made easier to navigate by including features like handrails, ramps, and mild inclines [36].

(ii) **Natural Landscape and Biodiversity:** Healing paths are often situated in scenic, natural settings rich in flora and animals. These settings offer a plethora

Table 1 Concept and components of healing trails

Components	Description	References
Design for accessibility	Incorporates features for people with diverse physical abilities, ensuring inclusivity and access	[30]
Natural landscapes and biodiversity	Located in natural environments with diverse flora and fauna, offering sensory experiences	[31]
Rest areas and meditation points	Designated spaces for visitors to pause, practice mindfulness, and immerse in the surroundings	[32]
Interpretive signage and education	Provides information about nature, ecosystems, and health benefits, enhancing connection	[33]
Sensory elements	Incorporates features like wind chimes, fragrant plants, and textures to engage visitors' senses	[34]
Nature art and installations	Introduces artistic elements, sculptures, or installations that enhance aesthetic and engagement	[35]
Guided experiences	Facilitated walks led by trained guides, encouraging mindfulness and deeper nature connection	[32]
Ecotherapy and mental well-being	Supports mental health through nature immersion, reducing stress, anxiety, and promoting well-being	[33]
Physical activity and exercise	Encourages gentle physical activity such as walking, contributing to cardiovascular health	[23]

of sensory input, from sight to smell to touch to sound. Birdsong, running water, and native flora all help create a peaceful and rejuvenating environment [31].

(iii) **Rest and Meditation Points:** Along the route, there are a number of spots set aside as rest spaces or meditation spots. These areas encourage guests to take a moment for reflection, practice meditation, or simply unwind in the midst of breathtaking scenery.

(iv) **Interpretive Signage and Education:** Many healing trails have educational and interpretive signage to inform visitors about the ecosystems they're visiting and the possible health benefits of spending time outdoors. This improves the experience as a whole by encouraging a more intimate bond with one's environment [32].

(v) **Sensory Elements:** Healing pathways sometimes include wind chimes, scented plants, and textured surfaces to stimulate the senses of visitors and promote a meditative state of mind. These factors aid in relieving tension and encouraging calm [34].

(vi) **Nature Arts and Installations:** Healing pathways can incorporate artistic installations, sculptures, and other forms of creative expression into nature. These additions improve the therapeutic atmosphere by providing visual stimulation and room for individual expression [29].

(vii) **Guided Experiences:** Mindful Nature Interaction is facilitated on some healing trails through the use of guided experiences conducted by qualified facilitators. Deep breathing, exploring your senses, and thinking about the world around you are all possible on these walks [32].

(viii) **Ecotherapy and Mental Well-Being:** Healing trails are intended to promote psychological wellness as a form of ecotherapy. Spending time in natural settings has been shown to alleviate stress, depression, and anxiety. People in need of peace and restoration can find it on a healing trail [33].

(ix) **Physical Activity:** Walking or light trekking on a healing trail is a great way to get some exercise and improve your cardiovascular health, muscle strength, and general fitness. Different levels of difficulty on the paths could be an intentional design choice.

(x) **Social Interaction and Community Engagement:** Opportunities for social contact and community involvement can be found in healing paths. Group walks, outdoor workshops, and events allow people who are interested in the same things to meet each other [23, 37].

2.3 Historical Perspectives of Healing Trails

The word "healing trails" itself may not have been regularly used in all periods and civilizations, but the idea of healing pathways has historical roots. The basic idea of using natural environments for therapeutic purposes has been around for a long time, even if the language and specific practices have changed through time. Thus, integrating indigenous medicinal plant walks into the Healing Trails concept draws on a long heritage of people using the outdoors to improve their health and well-being. Cultures all around the world have historically depended on their understanding of herbal remedies to treat a wide range of illnesses and boost general health. Humanity's continuing connection with nature healing is illuminated via the past accounts of historical significance and traditional medical value linked with Healing Trails.

The Egyptians, the Greeks, and the Chinese all left behind written documents about the medical uses of plants. Ancient Egyptians widely used herbal medicine for the prevention and treatment of illness [38]. Traditional Chinese medicine, which dates back thousands of years, takes a similar holistic approach by focusing on restoring the body's natural energy balance through the use of herbs [39]. Hippocrates, the ancient Greek physician frequently called the "father of medicine," promoted the therapeutic application of medicinal plants as a means of treating illness and promoting wellness [40, 41].

Medicinal plant knowledge is an important part of indigenous tribes' history and identity, and it has been handed down orally from generation to generation. For example, for generations, Native American communities have relied on plant-based medicines thanks to a thorough grasp of the plants' therapeutic characteristics [42]. Like their Asian and South American counterparts, indigenous physicians in African cultures have long used their familiarity with native plants to aid in physical recovery and mental reorientation [43–45].

The following eras illustrate the development of healing trails:

(i) **Ancient Cultures and Nature Retreats:** Recognizing the restorative and revitalizing advantages of time spent in natural environments, humans have been taking use of them since ancient times. For example, the ancient Greeks built special hospitals called "Asclepia" in honor of the deity Asclepius, where people may go to be healed on all levels of being [46]. The tranquilly of these havens was aided by the presence of things like beautiful gardens and calming water features.

(ii) **Japanese Tradition of Forest Bathing:** The Japanese practice of "forest bathing" is emblematic of the country's long-held belief in the curative powers of nature. Since the 1980s, Japan has actively pushed "Shinrin-yoku," also known as "forest bathing," in which people spend time in a forested setting. Ancient Shinto and Buddhist teachings that honor the spiritual link between humans and nature are the inspiration for this practice [26].

(iii) **Nineteenth-Century Nature Cure Movement:** The "nature treatment" movement of the nineteenth century gained traction in both the Old World and the New World [47]. The proponents of nature cure held that exposure to natural elements, such as the outdoors, might have beneficial health effects. By encouraging exercise, fresh air, and connection with nature, healing trails and sanatoriums aim to facilitate complete health and wellness [48].

(iv) **Growth of National Parks and Recreation Areas:** Many countries began creating national parks and other protected areas in the late-nineteenth and early twentieth centuries. The purpose of these preserved green areas was to offer people a place to unwind, recharge, and enjoy nature. In order to promote the health of both visitors' bodies and minds, trails were built inside these locations [49].

(v) **Modern Ecotherapy and Mindfulness Practices:** In recent decades, the idea of healing trails within the context of ecotherapy and mindfulness practices has received increased interest. Spending time in natural environments has been studied by many including Zhu et al. [50], Bratman et al. [51], and Pretty et al. [52] in the mental health and research fields for its potential to alleviate stress, anxiety, and depression. Individuals can take time for reflection and contemplation on trails created with an emphasis on mindfulness and sensory sensations.

(vi) **Contemporary Wellness and Green Infrastructure:** As wellness and environmentally responsible city planning have gained prominence in recent years, so too have healing trails become a standard feature of today's green infrastructure. In an effort to improve residents' health and well-being, as well as foster a stronger sense of community, several cities are including nature paths and green spaces into their urban development. Even in highly crowded places, these pathways provide city inhabitants with access to nature and its restorative benefits [53].

2.4 Indigenous Medicinal Practices in Healing Trails

Indigenous healing practices are a big part of what makes Healing Trails what they are. They give these recreational areas a sense of cultural history, indigenous wisdom, and an in-depth knowledge of how medicinal plants heal. Indigenous people all over the world have used their close relationship with nature to find and use plants to treat different illnesses and improve their general health for hundreds of years. Integrating native healing practices into Healing Trails not merely shows respect for the knowledge of these communities, but it also gives tourists an unforgettable experience that helps them understand how nature and health are connected.

Indigenous people in places like South America have a deep understanding of medicinal plants that have been passed down orally and is used by shamans and other traditional physicians [54, 55]. For example, the Amazon jungle is a storehouse of biodiversity that is home to a wide range of plants that have been used by native tribes for healing [56]. By adding these herbal remedy walks to Healing Trails, visitors can learn from the deep knowledge of indigenous people. They can learn about their traditional ways of healing and what these plants mean to them culturally.

Native American tribes in North America have used plants as medicine and for spiritual reasons for a long time. For example, the Cherokee people have a long history of using different plants to treat sicknesses and keep themselves healthy [57]. By adding traditional Cherokee herbal remedy walks to Healing Trails, the cultural history and indigenous understanding of these native communities are kept alive and shared with a wider audience.

Indigenous healing practices in Healing Trails also show how important it is to harvest and save resources in a way that doesn't hurt the environment [58, 59]. Voeks and Leony [60] observed that many indigenous groups have come up with ways to harvest plants in a way that protects medicinal plant species and keeps these

Table 2 Some indigenous medicinal practices and healing trail components

Indigenous medicinal practices	Healing trail components	References
Amazon rainforest medicinal plants	Medicinal plant walks, traditional healing	[61]
Cherokee herbal tradition	Medicinal plant walks, cultural heritage	[57]
Maori Rongoā (New Zealand)	Medicinal plant walks, traditional knowledge	[62]
Ayurvedic medicine (India)	Medicinal plant walks, holistic healing	[63, 64]
Traditional Chinese medicine	Medicinal plant walks, energy balance	[65]
Inuit healing traditions (Arctic)	Medicinal plant walks, spiritual practices	[66]
Sami traditional medicine (Scandinavia)	Medicinal plant walks, reindeer herding	[67, 68]
Navajo healing practices (USA)	Medicinal plant walks, sacred landscapes	[69]
Hawaiian Lāʻau Lapaʻau	Medicinal plant walks, cultural heritage	[70]
Ainu traditional medicine (Japan)	Medicinal plant walks, cultural revival	[71]

resources around for a long time. Healing Trails can help protect medicinal plants and protect culture and biodiversity by working with indigenous groups and learning from how they do things.

Thus, healing trails celebrate the cultural history and indigenous knowledge of communities by incorporating their healing practices. This gives visitors a deep experience of healing and connection with nature. Healing Trails become places of cultural appreciation, natural conservation, and whole-person well-being when they include medicinal plant walks based on indigenous knowledge (Table 2).

2.5 The Importance of Healing Trails in Safekeeping Historical Relics

Healing trails are meant to help people feel better about themselves as a whole and get closer to nature. These places also have important historical relics, artifacts, or ancient sites that need to be protected (Table 3). To safeguard the rich tapestry of human culture and history and to give visitors a valuable and educational experience, it is important to keep these historical artifacts safe in Healing Trails.

Along Healing Trails, you might find old buildings, artifacts made by native people, or traces of past cultures. These items tell us a lot about how our ancestors lived, what they believed in, and what kind of societies they lived in [82]. Healing Trails are becoming more popular as places to go for fun. This means that they are getting more and more users, so it is important to take steps to protect these relics from being accidentally damaged or worn down.

By adding historical artifacts to Healing Trails, there is a chance to teach about and protect cultural history through sustainable tourism. Signs and interpretive installations can be put in a way that tells visitors about the relics' historical importance and helps them understand their cultural worth and significance [83]. Also, barring direct entry to delicate regions can keep tourists from accidentally hurting the artifacts while still letting them understand their historical significance.

Table 3 Examples of historical sites and relics that benefit from healing trails

Historical site or relic	Country	References
Angkor Wat	Cambodia	[72]
Petra	Jordan	[15]
Acropolis of Athens	Greece	[57]
Machu Picchu	Peru	[73]
Chaco Culture National Historical Park	USA	[74]
The Great Wall of China	China	[39]
Ayutthaya Historical Park	Thailand	[15]
Stonehenge	United Kingdom	[75]
Teotihuacan	Mexico	[76]
Great Zimbabwe	Zimbabwe	[77]
Palmyra	Syria	[78]
Borobudur	Indonesia	[79]
Ephesus historical sanctuary	Turkey	[80]
Stone circles of Senegambia and the Gambia	Senegal and the Gambia	[81]

For the safekeeping of historical artifacts, it is important to work with community members, archaeologists, and antique experts. Engaging these groups can help create management plans that meet the needs of both leisure and preservation [84]. Regular monitoring and care, based on the advice of experts, can make sure that the relics stay in good shape and can be seen by future generations.

The Australia International Council on Monuments and Sites (ICOMOS) and para llevar a cabo Estudios report of 1999 says that the growth of Healing Trails can be guided by ethical principles like those in the ICOMOS International Cultural Tourism Charter [85]. These principles can help protect the integrity of historical artifacts. Healing Trails can help promote cultural respect, ecological responsibility, and sustainable tourism by finding a compromise between leisurely pursuits and cultural preservation. In summary, keeping historical artifacts safe in Healing Trails is an important part of preserving cultural history and being a good tourist.

2.6 Benefits of Cultural Integration of Healing Trails and Recreational Development

Healing Trails' cultural incorporation into recreational planning and development provides numerous, substantial benefits. Healing Trails are more than just trails; they develop into places for cultural festivities, learning, and conservation efforts as they incorporate indigenous knowledge and practices. Some major advantages are as follows:

(a) **Preservation of Cultural Heritage**

Traditional indigenous knowledge, customs, and practices can be preserved by the incorporation of cultural aspects into Healing Trails. Healing Trails ensure that cultural traditions are passed on from one generation to the next by serving as a showcase for such elements [72].

(b) **Improved Service for Tourists**

Incorporating local culture enhances the atmosphere and makes guests feel like they have stepped back in time. Recreating in a place where you have a deeper understanding of its cultural value through the study of its herbal remedies, traditional healing practices, and historical artifacts is a rewarding experience [57].

(c) **Participatory Democracy and Local Autonomy**

Planning and developing Healing Trails in collaboration with community members and indigenous groups gives them a voice in the preservation of their culture. Environmentally friendly and responsible tourist practices are encouraged, and a sense of ownership, as well as satisfaction, is fostered [15].

(d) **Environmental Protection**

The preservation of natural resources and ecosystems is a central theme in many culturally integrated societies. Healing Trails promote environmental stewardship and appropriate use of land, leading to long-term conservation efforts [86] by emphasizing the cultural relevance of the terrain and its biodiversity.

(e) **Education and Awareness**

Visitors to healing trails that make use of cultural features are usually able to learn about other people's customs, history, and healing methods. As such, integrating healing trails with cultural integration encourages people to learn about other people's cultures and appreciate them [87]. In a nutshell, there are several benefits for incorporating Healing Trails' cultural aspects into recreational design and development. Together, people, nature, and cultural diversity are celebrated in these holistic and meaningful spaces created through the integration of paths that serve several purposes, such as the preservation of cultural heritage, the promotion of environmental protection, and the enrichment of visitor experiences.

3 Healing Trails and Mental Health

Integrating therapeutic experiences in nature into Healing Trails has shown promise as a method of improving people's emotional and psychological well-being. Healing Trails are frequently built using biophilic design concepts, which involve the intentional use of natural materials and designs to foster feelings of well-being and oneness with the outdoors. The incorporation of the biophilic design helps to alleviate stress and boost cognitive performance [88]. Also, rhythms in nature, such as the trickle of water or the rustle of leaves, can have a relaxing effect on people, and Healing Trails often lead their visitors through a variety of natural settings. These ambient noises have been shown to reduce stress and promote calmness [89]. Other benefits include the following:

(a) **Reducing Stress and Improving Relaxation**

People can get away from the hustle and bustle of everyday life and recuperate their lives on a Healing Trail. Because of the increased stress levels caused by urbanization and frequent exposure to technology, therapies rooted in nature are gaining popularity. Studies have shown that visiting a Healing Trail might help you unwind and forget about your worries. The stress hormone cortisol was significantly reduced after exposure to natural habitats like those found on Healing Trails, according to research by Hartig et al. [15]. We can find the tranquilly and peace that in nature make it the perfect place to forget about the past and focus on the here and now.

(b) **Enhanced Happiness and General Emotional Health**

Participation in Healing Trails has been shown to improve mental and emotional health. Endorphins are neurotransmitters that are released in response to physical activity, and these trails are a great place to get some exercise and feel good about life. The peace and splendor of nature have the power to inspire awe and astonishment and boost the spirit. Joye et al. (2020) and Hartig et al. [15] found that spending time in natural settings boosted good emotions and dampened negative ones. These results demonstrate the therapeutic value of Healing Trails for fostering emotional health and optimism.

(c) **Improved Brain Power**

Healing Trails emphasizes the ways in which contact with nature can improve not just physical health but also mental acuity. Directed attention fatigue, brought on by the constant demand placed on one's brain in a city, can be alleviated through time spent in a more natural setting. Kaplan's [90] Attention Restoration Theory (ART) suggests that spending time in natural settings has positive effects on brain function, such as restoring focus and sparking inspiration. Healing Trails provide a respite from the stresses of daily life, restoring one's ability to think clearly and concentrate.

(d) **Decreased Worry and Depression**

Anxiety and despair can be greatly alleviated with the help of Healing Trails. Healing Trails' peaceful setting and proximity to nature are ideal for relieving stress and emotional distress. Participants in the study by Bratman et al. [91] who went on a 90-min walk in the woods reported significantly reduced ruminating, an important risk factor for depression. Individuals with mental health issues can find comfort and emotional relief through the healing power of nature through the Healing Trails' immersive experience.

(e) **Enhanced Resilience and Coping**

The time spent in nature healing trails strengthens emotional fortitude and enables more effective coping. Having access to natural areas that provide solace and support can help make life's hardships more manageable. Inspiring hope and a sense of rebirth in the face of adversity, nature's dynamic and adaptable qualities serve as a potent reminder of life's cyclical nature [92].

(f) **Social Connection and Support**

Nature healing trails makes it easier to connect with others, which is important for our mental health. Outdoor activities are a great way to spend quality time with loved ones and build memories that will last a lifetime. Nature-based interactions can boost the sense of connectivity between people, which is an effective defense against anxiety, depression, and stressful situations [93].

(g) **Mindfulness and Presence**

Being outside is a great way to practice mindfulness and live in the here and now. Individuals can take a mental vacation from thinking about their past or their future by taking in the sights, sounds, and fragrances of their natural surroundings as they move along the healing trails [92]. Research has found a correlation between mindfulness and improved mental and emotional health as these methods can help people feel less anxious and more at ease [94].

3.1 The Calming or Mood-Lifting Effects of Healing Trails

Medicinal plants have been used into Healing Trails and ecotherapy practices for their relaxing and mood-lifting benefits. These plants (Table 4) have natural therapeutic characteristics that help reduce stress, ease anxiety, and boost mood. Specific medicinal herbs that have been shown to have a sedative or mood-enhancing effect include as follows:

One of the most well-known plants for its sedative effects is lavender (*Lavandula* spp.). The calming and comforting odor of this plant has been studied [110]. Visitors to Healing Trails will find a relaxing atmosphere thanks to the abundance of lavender plants.

The relaxing and tranquil qualities of chamomile (*Matricaria chamomilla*) make it a popular herbal remedy. Anxiety symptoms are alleviated and sleep quality is enhanced, according to research [97]. A visit to Healing Trails is sure to calm and relax you thanks to the calming chamomile aroma that permeates the area.

Table 4 Calming and mood-lifting effects of some medicinal plants

Plant	Calming or mood-lifting effects	References
Lavender (*Lavandula* spp.)	Anxiety reduction, relaxation, improved sleep quality	[95, 96]
Chamomile (*Matricaria chamomilla*)	Anxiety reduction, improved sleep quality	[97]
St. John's Wort (*Hypericum perforatum*)	Potential mood improvement	[98]
Passionflower (*Passiflora incarnata*)	Anxiety reduction, relaxation	[99]
Lemon Balm (*Melissa officinalis*)	Uplifting, potential mood enhancement	[100]
Rose (*Rosa* spp.)	Stress reduction, mood improvement	[101]
Peppermint plant	Uplifting, increased alertness, mental clarity	[102]
Bergamot (*Citrus bergamia*)	Anxiety reduction, relaxation	[103]
Valerian (*Valeriana officinalis*)	Relaxation, potential anxiety reduction	[98]
Frankincense (*Boswellia* spp.)	Stress reduction, potential mood enhancement	[104]
Vetiver (*Vetiveria zizanioides*)	Calming, relaxation	[105]
Clary Sage (*Salvia sclarea*)	Potential mood enhancement, relaxation	[106]
Sandalwood (*Santalum* spp.)	Relaxation, potential anxiety reduction	[107]
Ylang Ylang (*Cananga odorata*)	Uplifting, relaxation	[101]
Patchouli (*Pogostemon cablin*)	Calming, relaxation	[101]
Geranium (*Pelargonium* spp.)	Uplifting, potential mood enhancement	[108]
Cedarwood (*Cedrus* spp.)	Relaxation, potential anxiety reduction	[109]
Marjoram (*Origanum majorana*)	Calming, relaxation	[101]
Neroli (*Citrus aurantium*)	Uplifting, potential anxiety reduction	[101]

Melissa officinalis (Lemon Balm) is a plant that has been used for centuries for its calming effects. Historically, it has been employed in the treatment of depression and anxiety [100]. Adding lemon balm to Healing Trails has been shown to increase feelings of happiness and calm.

Rose (*Rosa* spp.) fragrance has been shown to reduce stress and boost mood. Hongratanaworakit [101] found that inhaling rose essential oil reduced anxiety and increased calmness. The healing and restorative atmosphere of Healing Trails is enhanced by the roses that bloom there.

Citrus bergamia (Bergamot) essential oil has been shown to reduce anxiety and boost mood. Alkofahi and Atta [103] found that bergamot aromatherapy reduced both heart rate and blood pressure, producing a calming effect. Visitors to Healing Trails with bergamot should expect to feel revitalized and refreshed.

Cananga odorata (Ylang Ylang) is a flowering plant whose essential oil has been used for centuries for its calming and sedative properties. Psychological stress responses can be mitigated through the use of ylang ylang aromatherapy [101]. Ylang ylang is a pleasant addition to Healing Trails, helping visitors unwind and regain equilibrium.

Vetiver (*Vetiveria zizanioides*) has been used for centuries for its relaxing and grounding effects. The aroma has been shown to have calming effects on the mind and body [105]. Adding vetiver to Healing Trails can help people feel more grounded and relaxed.

Salvia sclarea, or clary sage, is also on the list because of its calming and mood-boosting effects. The stress hormone cortisol is lowered by inhaling clary sage essential oil [106]. Clary sage, which is used in Healing Trails, has been shown to improve mental health.

Frankincense (*Boswellia* spp.) also has a calming and inspiring properties. The scent of this plant has been shown to calm anxious feelings and boost mood [104]. When visiting Healing Trails, you may find the presence of frankincense to be enlightening to your soul.

Patchouli (*Pogostemon cablin*) is also considered beneficial because of its sedative and mood-balancing properties. It has been found to have calming effects simply through its scent [101]. Adding patchouli to Healing Trails is a great way to calm your mind and restore your equilibrium.

4 Urban Green Spaces and Healing Trails

The decline in urban greenery has contributed to a host of health problems experienced by city dwellers. However, a promising option to improve city dwellers' well-being is to incorporate Healing Trails, replete with medicinal plant walks, into urban green spaces. When it comes to counteracting the drawbacks of city life, urban green spaces are indispensable. As urban areas continue to grow, people's opportunities to connect with the environment are dwindling. Daily inhabitants can get away from the hustle and bustle of daily life and enjoy some time in nature by visiting one of the city's many green parks. Stress is reduced, air quality is enhanced, and community spirit is strengthened in these settings [111]. But having parks and other green areas may not be enough to improve people's quality of life in cities. The impact on public health is heavily dependent on the planning and function of these areas.

The goal of creating Healing Trails is to use the therapeutic effects of nature on the body, mind, and spirit (Fig. 1). The incorporation of Healing Trails into urban greenery provides inhabitants with a rare opportunity to reap the therapeutic advantages of nature in a curated and organized setting. There are usually designated spots along these routes where you can find medicinal herbs. Physical exercise, time spent in nature, and interaction with medicinal plants all work together to provide an integrative experience that benefits the health of city inhabitants.

4.1 Physical Health Benefits

Healing Trails make it simple for city inhabitants to fit exercise into their schedules by connecting parks and other green areas. There are likely medicinal plants that aid with respiratory health all along these pathways. Plants like eucalyptus have been

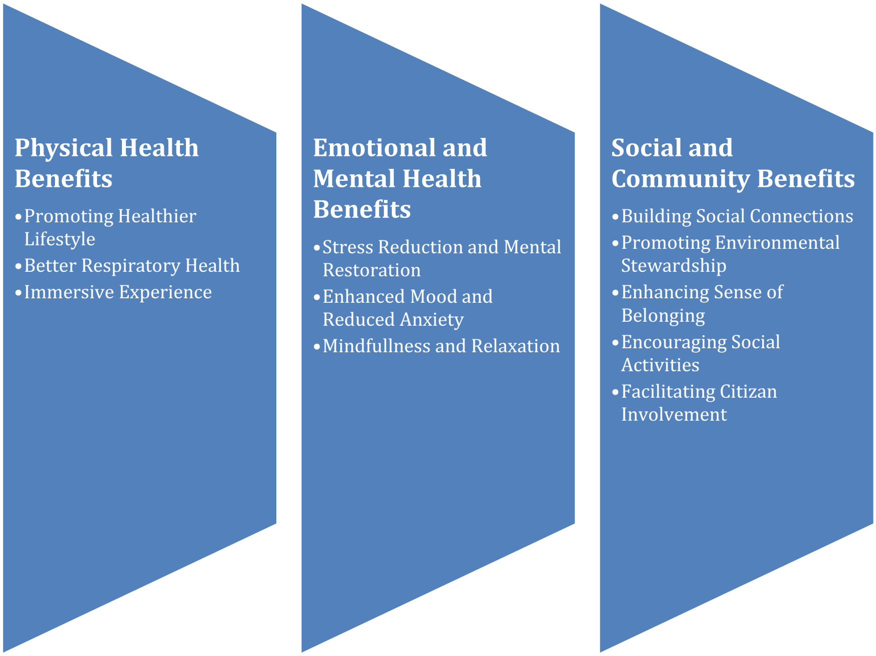

Fig. 1 Benefits of Healing Trails in urban green spaces

shown to improve lung function and reduce respiratory distress [112]. As a result, Healing Trails provide a potent tool for improving physical health and mitigating the negative consequences of city life. These include the following:

(a) **Promoting Healthier Lifestyles**

Walking, jogging, and hiking are just some of the physical activities that may be enjoyed in urban green spaces with healing trails. These routines not only improve cardiovascular health, but they also help prevent serious conditions like diabetes, heart disease, and obesity [113]. Urban green spaces provide easy access to exercise areas in visually pleasing surroundings, which is especially important for the health and happiness of city people. Healing trails motivate people to get out and about in these green areas, turning exercise into something people look forward to doing on a regular basis.

(b) **Immersive Experience**

For those who need a break from the city's typical concrete surrounds, healing pathways in urban green spaces provide an immersive experience in nature. Research has found that spending time in nature can improve health in several ways, including lowering blood pressure, decreasing cortisol levels, and boosting the immune system [114]. Humans have what is called a biophilic link or an inbuilt preference for natural settings that has been shown to improve health outcomes. Nature has a stress-relieving and mood-boosting effect because of its relaxing and rejuvenating qualities. The incorporation of healing paths into urban green spaces allows city inhabitants to find peace and quiet away from the chaos of the city.

(c) **Better Respiratory Health**

People who live in cities can benefit from medicinal plant walks since they are exposed to phytochemicals generated by different plants. For example, studies have linked eucalyptus with reduced respiratory symptoms [112]. Air pollution is a common problem in urban areas and can have harmful effects on people's respiratory systems. The negative effects of urban air pollution on the respiratory system can be mitigated by the existence of healing trails including specialized medicinal plants, such as eucalyptus. During medicinal plant walks, inhaling the plants' natural aromas may help clear airways, lessen respiratory irritation, and improve lung function.

4.2 Emotional and Mental Health Benefits

Research has linked time spent in green spaces and interacting with nature to lower stress levels, higher levels of happiness, and better memory and reasoning skills [91]. In contrast to the hectic pace of the city, Healing Trails offer a calm and peaceful setting ideal for introspection and rejuvenation. The therapeutic value of these treks is enhanced by the inclusion of interactions with medicinal plants. Lavender and chamomile, for example, are commonly used for their sedative and anti-anxiety properties [97]. The therapeutic plant aromas combined with the tranquil setting produce a potent environment for relieving stress and restoring emotional balance. Other emotional and mental health benefits include the following:

(a) **Stress Reduction and Mental Restoration**

Opportunities for relaxation and psychological recovery are made possible by the combination of urban green spaces with healing pathways and medicinal plant walks. Spending time in nature has been demonstrated to boost concentration and memory [94]. Access to green spaces provides a natural refuge for mental renewal, especially in metropolitan environments where the flow of life is often fast and stress levels are high. Healing trails help people relax, boost their mood, and regain concentration by combining time in nature with vigorous exercise.

(b) **Enhanced Mood and Reduced Anxiety**

Spending time in green places and interacting with nature has been shown to have a good effect on mood and alleviate anxiety and depression symptoms. Happiness and life satisfaction have both been shown to increase with time spent in nature [91]. Some of the medicinal plants found along healing paths have been shown to have mood-boosting effects, adding another layer to the overall experience. Lavender, for instance, has been linked to calmness and relaxation, while lemon balm is renowned for its energizing properties. Visitors can enjoy psychological wellness through their connection to nature and these plants in particular at urban green spaces that feature medicinal plant walks.

(c) **Mindfulness and Relaxation**

Healing pathways in urban green spaces provide a peaceful backdrop for mindfulness and relaxation exercises. It has been shown that interacting with medicinal herbs while meditation increases feelings of peace and relaxation [115]. Being in a beautiful natural setting can help with mindfulness practices, which focus on the present moment. Participants in medicinal plant walks often report feeling more relaxed and at peace after experiencing the sights, sounds, and scents of nature. This focused state helps you unwind, lowers your tension, and boosts your mood.

4.3 Social and Community Benefits

Urban green spaces linked with healing trails offer significant social and communal benefits in addition to physical and mental health benefits. These efforts may help city inhabitants feel more connected to one another, expand their social circles, and take better care of their local environments.

(a) **Building Social Connections**

Urban parks with healing trails can be community hubs where people can meet and get to know one another. Group walks and walks in search of medicinal plants are just two examples of the kinds of outdoor activities that bring people of all ages and walks of life together. This is because people are more likely to talk to one another and share ideas after participating in group activities [116]. Urbanites who take advantage of healing trails together strengthen their social networks through a shared experience of nature's restorative power.

(b) **Promoting Environmental Stewardship**

Incorporating medicinal plant walks into urban green spaces helps teach the community the value of safeguarding and preserving indigenous plants and ecosystems, which in turn promotes environmental stewardship. The medicinal value, ecological importance, and traditional uses of the plants along healing paths are often explained in interpretive materials and educational signage [117]. As city inhabitants gain knowledge of the plant's medicinal and cultural significance, they have a more meaningful relationship with nature and become more aware of the importance of preserving it. This increased environmental stewardship has the potential to go beyond parks and plazas to inspire sustainable lifestyle choices and citywide conservation drives.

(c) **Enhancing Sense of Belonging**

Urban parks with healing trails provide a shared space where urban people of all backgrounds and socioeconomic statuses can come together and strengthen their sense of community. By providing a place where everyone feels welcome, these places help residents develop a common sense of self [118]. The existence of healing trails increases people's awareness of the value of parks in urban areas and the therapeutic effects of spending time in nature. When people feel a connection to a therapeutic space, they become invested in keeping it healthy for the sake of the whole community.

(d) **Encouraging Social Activities**

Healing paths in urban green spaces make it possible for people to gather for a variety of group pursuits. Group activities, workshops, and educational programs about medicinal plant walks and nature-based therapy can be organized by collaborating community organizations, schools, and local businesses [119]. These events encourage participation from all individuals and bring together groups with varying backgrounds for dialogue and education. When people come together, the healing pathways blossom into bustling centers of community life that enhance the cityscape.

(e) **Facilitating Citizen Involvement**

Neighborhoods can take an active role in the development and upkeep of their urban green spaces by incorporating healing pathways and medicinal plant walks. Residents have the opportunity to contribute their ideas and experience to the planning, design, and implementation stages of these projects [120]. When people see how their efforts improve the lives of themselves and their neighbors, they feel a greater sense of pride in the green places in their community.

5 Complementary Medicine and Healing Trails

Complementary medicine, also known as holistic healthcare, is an umbrella term for a wide variety of non-Western approaches to health and wellness. Complementary medicine, which includes everything from acupuncture and herbal medicine to Ayurveda and Traditional Chinese Medicine, is an approach to health and wellness that takes into account the whole person rather than just treating symptoms [121, 122]. Complementary medicine relies heavily on the therapeutic use of medicinal plants, which highlights the powerful healing capabilities present in the natural world [123–128].

The value of healing trails along medicinal plants as part of complementary medicine practices has been increasingly acknowledged in recent years [129–132]. To learn about the identification, characteristics, and traditional usage of many medicinal plants, practitioners and participants go on medicinal plant walks, which are guided trips in natural environments [133]. Participants can interact with the plants up close and personal, smelling, touching, and even tasting them on these walks.

When complementary medicine, like healing trails, is used with conventional treatment, a synergistic effect is created that benefits both the patient and the healthcare provider [134]. These integrative therapeutic approaches provide a more thorough understanding of plant-based treatments and their uses by incorporating knowledge of herbal remedies from many cultural and historical viewpoints.

There is a rising curiosity in investigating natural and alternative methods of health and well-being as the globe struggles under an increasing load of serious illnesses and mental health difficulties. To achieve a more compassionate and inclusive healthcare paradigm, complementary medicine's emphasis on holistic care and individualized therapies is a good fit [122]. Practitioners and patients alike can benefit from a deeper understanding of nature, the healing power of plants, and self-care by participating in medicinal plant walks as part of the range of complementary medicine practices.

Besides helping healthcare professionals, healing trails encourage patient agency in the healing process. Insights on the safe and efficient use of natural treatments for minor medical conditions and preventive care are gained through medicinal plant walks [121]. By giving people more control over their own lives, we may increase their affinity with the natural world and inspire them to take action to protect medicinal plants and the habitats in which they thrive.

5.1 Benefits of Integrating Healing Trails in Complementary Medicine

(a) **Diversity of Healing Traditions**

When we talk about complementary medicine, we're talking about a vast range of healing modalities from all around the world. Practitioners and patients alike can benefit from medicinal plant walks of healing trails by learning about the wide range of plant usage in different healing modalities, such as TCM, Ayurveda, indigenous medicine, and European herbalism [122]. This sharing of ideas across cultures deepens our respect for traditional wisdom and creates a diverse tapestry of therapeutic approaches.

(b) **Personalized and Holistic Healing**

Healing that is both individualized and holistic can be achieved via the use of healing trails or medicinal plant walks and other forms of integrative medicine. Plants and cures are chosen with careful consideration of the individual's needs and physical make-up [135]. Practitioners gain further insight into their patients' emotional and mental health through the experiential side of medicinal plant walks, in which they may see how patients connect with plants and nature. This all-encompassing assessment helps create a more thorough, patient-specific therapy strategy.

(c) **Self-Care and Empowerment**

Medicinal plant walks encourage people to engage in self-care activities that improve their health and well-being. It has been shown that education on medicinal plants and their therapeutic capabilities can increase people's comfort and success with utilizing such treatments for common ailments and as a kind of preventative medicine [121]. This sense of control helps people feel more attuned to the natural world and more in charge of their own recovery.

(d) **Awareness and Conservation of the Environment**

The use of healing trails or medicinal plant walks as part of integrative healing raise awareness of and appreciation for the natural world. When people learn about medicinal plants and their use in healing, they gain a greater awareness of the interdependence of all living things in the natural world [136]. Increased environmental awareness promotes eco-friendly herb collection and responsible use, ensuring medicinal plants will be around for future generations to benefit from (Fig. 2).

5.2 Challenges and Considerations for Healing Trails and Complimentary Medicine

(a) **Ethical Harvesting and Sustainability:**

The use of medicinal plant trail walks for integrated treatment poses ethical harvesting and sustainability issues. Over harvesting and the extinction of some plant species may result from the rising demand for therapeutic herbs [137]. To guarantee the ethical use of plants, practitioners and participants must prioritize ethical practices such as wild-crafting rules and supporting cultivation efforts. The Forest Stewardship Council (FSC), for instance, publishes recommendations for responsible plant resource management and advocates for sustainable wild harvesting [138].

(b) **Safety and Knowledge of Practitioners:**

Practitioners using an integrative approach to therapy should be well-versed in the qualities and interactions of the plants they are working with to ensure the safety of their patients. When combining plant-based cures with other therapies or drugs, safety must be the top priority [139]. Integrative healing trail experiences can only be beneficial if practitioners have the knowledge and skills necessary to ensure the safety of their patients. Educators and Ayurvedic doctors have groups like the American Herbalists Guild (AHG) and the National Ayurvedic Medical Association (NAMA) to thank for their efforts to improve the field.

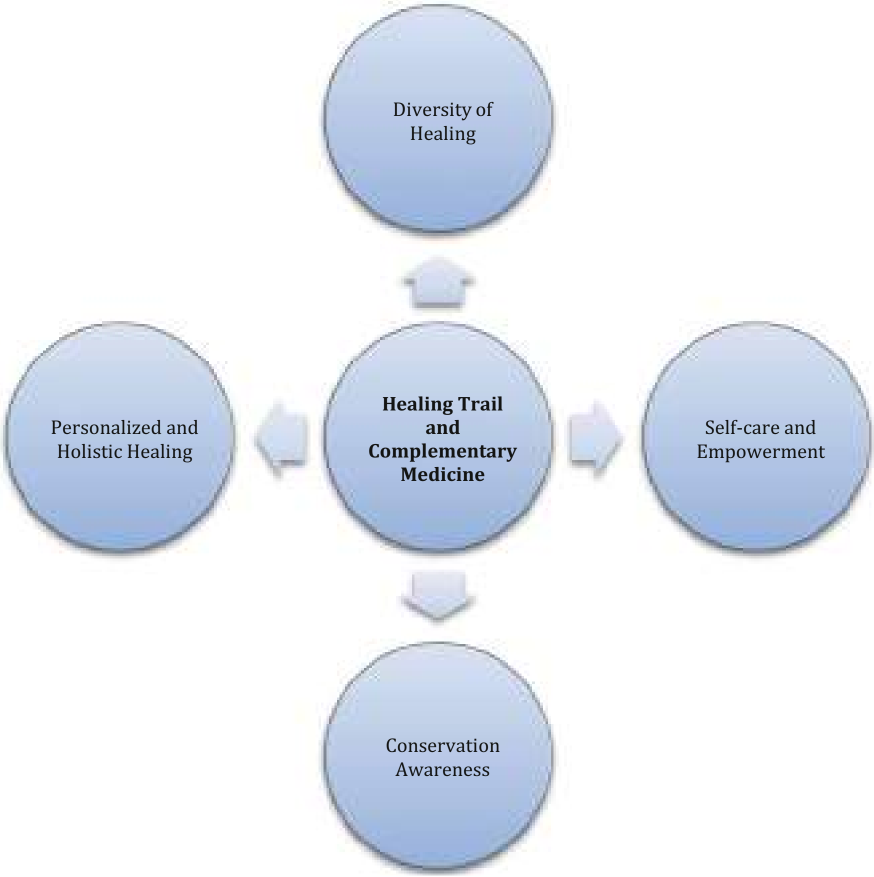

Fig. 2 Benefits of integrating healing trails in complementary medicine

(c) **Cultural Appropriation and Respect for Indigenous Knowledge:**

Given that medicinal plant trail walks rely on the expertise of indigenous and local people, it is important to recognize and address the potential for cultural appropriation [140]. Traditional healing knowledge should be used with an appreciation for and understanding of its historical context on the part of all practitioners and participants. Respect for and appreciation of indigenous elders' and healers' cultural practices and points of view can be achieved through collaboration and partnership [141]. In addition, the preservation and regeneration of traditional healing systems can benefit from appropriate recompense for the use of traditional knowledge and active efforts to promote Indigenous-led projects.

(d) **Evidence-Based Practices and Integration with Conventional Medicine:**

The integration of medicinal plant walks with complementary medicine practices and conventional medicine should be evidence-based, although traditional healing traditions provide vital insights into the usage of medicinal plants trail walks. Validating the safety and efficacy of plant-based medicines and informing their integration with traditional medical treatments requires research and clinical investigations [135]. To provide the most thorough and coordinated care for their patients, practitioners should work together with traditional medical specialists. Better integrated therapeutic practices can result from increased transparency and knowledge-sharing among various healthcare methods.

(e) **Individual Variability and Personalization:**

Because people have different reactions to plant-based treatments, an individualized strategy is necessary for effective integrative healing with medicinal plant trail walks. Individual differences in heredity, health problems, and allergies must be taken into account when prescribing herbal remedies [8] because not all plants are appropriate for all people. For optimal results from the use of medicinal plants, practitioners should conduct in-depth evaluations and consultations with patients.

6 Ecotourism and Sustainable Economic Development in Healing Trails

Ecotourism is described as "responsible travel to natural places that safeguard ecosystems and improves the well-being of local communities" [142]. When incorporated into ecotourism programs, healing trails and medicinal plant walks provide visitors with unique and enlightening experiences while also creating economic advantages for local communities. This section examines the possible benefits of healing trails and medicinal plant walks in ecotourism, focusing on their role in bolstering local economies and promoting long-term, sustainable growth.

6.1 The Impact on Neighborhood Economies

The creation of tourism earnings is one of the key economic benefits of healing trails and medicinal plant walks based on ecotourism. The opportunity to learn about plants' healing capabilities, forge meaningful connections with the natural world, and fully submerge oneself in restorative settings are some of the reasons why tourists flock to these special events [143]. Communities in proximity to healing trails might benefit from the resulting increase in tourism by providing services such as lodging, dining, and sightseeing to the growing number of visitors [44, 144–150]. Local economies benefit from these services because they help firms expand and new jobs are created.

(a) **Participation in Community Events and Cross-Cultural Dialogue**

Travelers and locals alike can learn from one another through ecotourism's use of healing trails and plant-based remedy hikes. By consulting with local guides and healers, tourists can acquire insight into the country's rich cultural history and traditional medical practices [151]. These kinds of exchanges improve everyone's capacity to appreciate and understand one another, which in turn boosts the ecotourism experience as a whole and makes visitors more likely to extend their stay and spend money in the local economy. The local community can also reap financial rewards from ecotourism by providing services such as guiding therapeutic plant walks, selling handicrafts, and imparting traditional knowledge.

(b) **Environmental Stewardship and Conservation Efforts**

Healing trails and therapeutic plant walks that are part of ecotourism help spread awareness about the importance of protecting natural resources. Communities have an interest in preserving ecological resources because efforts like these depend on the availability of natural habitats and therapeutic plants [152]. For ecotourism to thrive along the healing route into the future, residents must take an active role in conservation efforts and prudent land use [153]. This dedication to environmental conservation helps to preserve biodiversity and natural habitats, which in turn helps to secure the future prosperity of ecotourism.

(c) **Specialized Tourism and Market Diversification**

Visitors interested in alternative medicine and folklore are the target market for healing trails and medicinal plant walks, both of which fall under the umbrella of niche tourism. By highlighting these one-of-a-kind activities, towns may increase the variety of their tourism offers and appeal to a wider spectrum of visitors [154]. It is especially important for less popular tourist locations to diversify their visitor base. Communities can strengthen their economies and become less dependent on a select few sectors if they focus on satisfying the needs of specific subsets of the population.

(d) **The Renewal of Traditional Wisdom**

By combining ecotourism with the study of medicinal plants, traditional knowledge can be revitalized and preserved [155]. Tourists can learn from the experience and knowledge of local physicians and traditional healthcare providers by joining one of these walks [156]. Reviving cultural practices and instilling a sense of pride in the local population are two outcomes of recognizing and promoting indigenous knowledge systems. Additional financial opportunities may arise as a result of cooperation and partnerships with institutions of higher learning and research organizations made possible by such recognition.

6.2 Challenges and Considerations

While there is potential for substantial financial gain from ecotourism that centers on healing trails and medicinal plant walks, there are a number of obstacles that must be overcome to achieve long-term financial health. These include the following:

(a) **Responsible Tourism Management**

Ecotourism must be managed and regulated properly to prevent overcrowding and reduce the strain on natural and cultural resources [157]. To prevent damage to healing pathways and the ecosystems that surround them, sustainable tourism practices including visitor carrying capacity and trash management should be put into place.

(b) **Community Empowerment and Benefit Sharing**

Benefits and responsibilities from ecotourism projects should be shared with local populations, according to a report by Jacob and Ogogo [158] and Ukpong and Jacob [159, 160]. Economic advantages from ecotourism should be allocated equally among community members through established benefit-sharing systems to reduce wealth gaps and increase community cohesion.

(c) **Cultural Sensitivity and Respect**

Activities related to tourism should be carried out with sensitivity to and respect for local culture [154]. Positive ties between locals and tourists can be maintained by urging visitors to observe local laws and customs.

(d) **Environmental Conservation and Biodiversity Protection**

It is imperative that conservation efforts be prioritized in order to protect the natural ecosystems and medicinal plants that form the basis of healing pathways [152]. Sustainable ecotourism relies on the active participation of local populations in ecological restoration and biodiversity protection activities.

7 Healing Trails for Specific Health Conditions

There is growing evidence that suggests these methods can help with the treatment of a variety of health problems, including those connected to the respiratory system, the skin, and stress. Therapeutic advantages from nature can be maximized by creating specialized healing trails and therapeutic plant walks for those with various diseases. Some of the ailments include the following:

7.1 Respiratory Health Challenges

(a) **Asthma**

People who suffer from asthma should seek out healing paths in areas with low concentrations of air pollution, allergens, and irritants. The clean air found in forest and coastal locations is especially helpful for people with breathing problems [161]. Shinrin-yoku, or forest bathing, has been shown to help people with asthma by lowering their stress and inflammatory levels and enhancing their lung function [162]. Certain trees, such as conifers, have been proven to have therapeutic potential due to the essential oils they exude [163] for lowering bronchial inflammation and alleviating respiratory symptoms.

(b) **Chronic Obstructive Pulmonary Disease (COPD)**

Healing trails for people with COPD typically include lung- and heart-health boosting exercises. Moderate activity, including walking and climbing, can boost respiratory muscle strength and general fitness, and trails with varying terrains provide those possibilities [164]. Patients with chronic obstructive pulmonary disease (COPD) who spend time in natural settings may have less anxiety and depression, which could improve their ability to take care of their condition [165].

7.2 Stress-Relieving Hiking Trails

(a) **General Stress Reduction**

Healing trails for stress reduction aim to create an atmosphere of calm and serenity to aid in the process of unwinding and improving one's state of mind. Ecotherapy, often known as green therapy, is the practice of spending time in natural environments with the intention of improving one's mental and emotional health [166]. Stress can be reduced and mental stability can be fostered by spending time in natural environments like parks and gardens [167].

(b) **Post-Traumatic Stress Disorder (PTSD)**

Healing paths for people with PTSD typically feature serene and secure settings. Trauma survivors can benefit from spending time in natural settings that have been stripped of triggering elements [168]. Healing trails can integrate mindfulness-based practices like meditation and guided nature walks to help people with PTSD deal with anxiety and unwanted thoughts [169].

7.3 Evidence Supporting the Effectiveness

(a) **Physiological Benefits**

Numerous studies have demonstrated the physiological advantages of time spent outdoors. It has been shown that spending time in nature can help reduce stress and improve physiological responses [170, 171] by lowering cortisol levels, slowing the sympathetic nervous system, and speeding up the parasympathetic nervous system. Researchers have found that people whose lungs aren't functioning properly benefit from spending time in forest surroundings [172].

(b) **Psychological Well-Being**

Healing paths and walks among medicinal plants have been shown to improve mental health in numerous studies. Berto [94], Capaldi et al. [173], and Roe and Aspinall [119] all found that people who engaged in nature-based therapy reported fewer anxious and depressed sensations, greater enjoyment and contentment, and enhanced cognitive function. Time spent in nature has also been linked to improved stress resistance and coping strategies [118, 166].

(c) **Immune System Enhancement**

To boost the immune system, which can be especially helpful for people with chronic health disorders, nature-based therapies have shown promise [174]. It has been observed that being exposed to phytoncides, natural substances emitted by trees, increases natural killer cell activity and the synthesis of anti-cancer proteins [175]. Improved immune response and decreased inflammation have also been linked to mindful meditation in healing trails [176].

(d) **Medicinal Plant Walks' Potential Health Benefits**

Different plant chemicals have shown promise in the management of health disorders, therefore medicinal plant walks can have a definite therapeutic effect. For instance, the chamomile plant (*Matricaria chamomilla*) has been shown to provide sedative effects and alleviate tension [97]. Anxiety and insomnia can be alleviated with the use of lavender (*Lavandula angustifolia*), according to research [177]. The anti-inflammatory and wound-healing characteristics of aloe vera (*Aloe barbadensis miller*) make it useful for treating skin diseases [178]. Due to its antibacterial and anti-inflammatory qualities, eucalyptus (*Eucalyptus globulus*) is beneficial for the respiratory system [179].

8 Visitors' Accessibility and Inclusivity in Healing Trails

Accessibility and inclusion for people with disabilities and people of different cultural backgrounds are of the utmost importance if nature-based therapies are to reach their full potential. Healing trails and therapeutic herb walks can be inclusive settings that give people agency regardless of their limitations, sensory preferences, or cultural background if they remove obstacles to entry. Embracing diversity and fostering fairness in nature-based healing experiences are discussed in this section, along with the significance of making healing trails accessible and inclusive.

(a) **Physical Accessibility**

Creating healing trails and medicinal plant walks accessible to those with disabilities and limited mobility begins with addressing the issue of physical access. The use of wheelchairs and other mobility aids is made easier on trails that have been built with accessible walkways, ramps, and railings [180]. Visitors can better plan their time on the path with the use of clear signs, maps, and information regarding the trail's accessible features [181]. Moreover, trail planners should think about where to put benches so that people of all abilities can stop and take in the scenery.

(b) **Sensory Accessibility**

Constructing sensory-friendly healing trails can greatly improve the quality of nature-based activities for those with sensory disorders. Those who have trouble seeing print may benefit from audio or tactile interpretations [182]. Those with sensory processing impairments can participate in meaningful outdoor activities thanks to sensory gardens that include a variety of scented plants and textures [183]. It is possible to create a pleasant and stress-free environment for everyone by strategically placing calm areas along the trail.

(c) **Cultural Inclusion**

To ensure that people from all walks of life may benefit from healing trail walks, it is important to encourage cultural inclusion. Cultural exchange and acknowledgement are encouraged by involving local communities in the trail's planning and development, as well as by incorporating their traditional knowledge and practices into the trail's interpretation [184]. Because of the diversity of trail visitors, it is important to provide information and interpretation in multiple languages. Trail guides and staff that have received empathy and cultural awareness training can better meet the needs and preferences of all tourists [185].

8.1 Barriers to Accessibility and Participation in Healing Trail Walks

The Barriers to accessibility and participation of individuals in healing trails (Fig. 3) are discussed below.

(a) **Physical Barriers**

(i) **Inadequate Infrastructure:** Without proper infrastructure like accessible walkways, ramps, and handrails, people with mobility issues or physical disabilities face substantial challenges when trying to use healing trails [186]. Wheelchair users and others who rely on mobility aids may have difficulty navigating the trail due to its uneven surface, steep inclines, and lack of resting spots.

(ii) **Limited Restroom Facilities:** The lack of wheelchair-accessible restrooms along the trail is a major barrier for people with mobility impairments. People who are visiting must have easy access to restrooms in case they need to take frequent breaks or have special needs.

(b) **Sensory Barriers**

(i) **Lack of Interpretive Materials:** One barrier to full participation in healing trails for people with visual impairments is the absence of accessible interpretive materials in formats such as braille or audio [187]. Individuals with visual impairments may be limited in their ability to participate due to a lack of descriptive audio or tactile components.

(ii) **Noisy or Overstimulating Environments:** Individuals with sensory processing issues or neurodevelopmental conditions may have difficulty on healing trails that offer noisy or overstimulating situations. Discomfort

• Physical Barriers	◆ Inadequate Infrastructure ◆ Limited Restroom Facilities
• Sensory Barriers	◆ Lack of Interpretive Materials ◆ Noisy or Overstimulating Environment
• Cultural Barriers	◆ Lack of Representation ◆ Communication Issues
• Financial Barriers	◆ High Entry Fees ◆ Lack of Funding for Accessibility
• Knowledge and Awareness Barriers	◆ Limited Information ◆ Lack of Education and Training
• Social Barriers	◆ Stigma and Misconceptions ◆ Lack of Social Support
• Transport and Location Barriers	◆ Ease of accessing ◆ Distance

Fig. 3 Barriers to accessibility and participation in healing trail walks

caused by excessive crowding or noise may discourage people from taking part.

(c) **Cultural Barriers**

(i) **Lack of Representation:**

To begin, healing trails may not connect with people of different cultural communities if they don't include cultural representation or information from multiple backgrounds [188]. People of different cultural origins may feel excluded and like the healing process doesn't apply to them if their culture isn't well represented.

(ii) **Communication Issues:** Some people may feel left out if healing paths only provide information in one language. Making the experience accessible to persons of different language origins requires the use of multilingual signs and interpretative materials [189].

(d) **Financial Barrier**

(i) **High Entry Fees**: People with fewer financial resources may be deterred from visiting healing trails with high entry costs [190]. Access to nature-based therapeutic experiences might be hindered by barriers such as the price of admission, transportation costs, and other related fees. All people, regardless of their financial situation, should be able to make use of healing paths and medicinal plant hikes. Providing free or discounted entry, or community-based programs, can widen access to nature-based therapeutic experiences and eliminate cost obstacles [190]. Through partnerships with neighborhood institutions like schools, community centers, and social service organizations, we may reach out to disadvantaged neighborhoods and remove financial barriers to participation.

(ii) **Lack of Funding for Accessibility:** Inadequate funding for accessible healing pathways can impede attempts to eliminate physical and sensory barriers. Ramps, accessible walkways, and alternate format interpretative materials may not be possible due to financial limits.

(e) **Knowledge and Awareness Barriers:**

(i) **Limited Information:** Planning a trip to a healing trail can be difficult for some because of a lack of knowledge regarding the path's accessibility features [181]. It can be discouraging to try out a new path if you have doubts about whether or not it will accommodate your particular demands.

(ii) **Lack of Education and Training:** There may not be enough knowledge and training for trail guides and personnel on how to accommodate people with impairments or from different cultural backgrounds [191]. Barriers to participation may arise unintentionally due to a lack of understanding of accessible communication and cultural sensitivity.

(f) **Social Barriers**

(i) **Stigma and Misconceptions:** Exclusion and prejudice can result from social stigma and false beliefs about someone based on their disability or cultural background [192]. People's participation in healing trails could be hindered by preconceived notions and biases.

(ii) **Lack of Social Support:** Due to a lack of social support, it may be difficult for people with disabilities or from marginalized populations to participate in healing trails on their own [193]. Isolation and lack of engagement may result from a lack of support from friends and family.

(g) **Transportation and Location Barriers**

Accessibility to healing trails and medicinal plant hikes should be planned with transportation and location in mind. Those without access to a car will have an easier time visiting trails that are close to major transportation nodes or have convenient parking options [194]. The inclusion of people with mobility problems might be bolstered by advertising shuttle services and other accessible transportation options.

8.2 Benefits of Accessibility and Inclusivity of Healing Trails

(a) **Enhanced Well-Being and Health Outcomes**

Expanding access to nature-based therapies by creating universally accessible healing pathways and medicinal plant walks. Researchers have found that spending time in nature has positive effects on health and happiness [118, 166]. More people will benefit from these outcomes and be able to contribute to better public health if obstacles are removed and everyone has the same opportunity to participate.

(b) **Social Cohesion and Community Engagement**

Healing trails that are easily accessible to all people bring people from different walks of life together, which is good for promoting social cohesion and community involvement [195]. A sense of community is fostered through outdoor activities that bring people of different backgrounds together, according to research [196]. Having more people to talk to helps build a community where everyone feels welcome.

(c) **Empowerment and Sense of Agency**

Accessible healing trails walk give people with disabilities the freedom to discover the outdoors on their own terms while still receiving the benefits of nature-based healing [197]. This boosts their sense of autonomy and allows them to take control of their own health and well-being. Fox and Magnus [198] asserted that when people feel that they have some control over their own lives, they tend to have a more favorable view of themselves. Furthermore, fostering diversity and inclusion in outdoor activities strengthens the conviction that nature is a place for all people.

(d) **Cultural Preservation and Promotion**

Healing paths that incorporate traditional knowledge and practices from a variety of cultures help to maintain and promote that heritage [199]. Visitors can gain a deeper understanding of and appreciation for alternative approaches to health and wellness by participating in events that highlight cultural diversity [200]. By serving as meeting places for people from different cultures, healing paths help revitalize and preserve indigenous ways of life.

9 Plant Identification and Ethical Foraging in Healing Trails

Healing trails and medicinal plant walks rely heavily on participants' ability to identify plants and to forage in a responsible manner. Through these activities, people are able to forge meaningful connections with the natural world, gain insight into the healing potential of plants, and experience these treatments themselves. To guarantee the safety and sustainability of medicinal plant use, however, it is essential to conduct plant identification and foraging with integrity and reverence for the environment. This section reinforces ethical foraging techniques to protect nature's healing treasures and offers tips for identifying plants along healing pathways.

9.1 The Value of Proper Plant Labelling and Identification in Healing Trails

In order to improve the healing trail experience for visitors and encourage the responsible and safe use of medicinal plants, accurate plant labeling and identification are of the utmost importance. Proper plant labeling educates and encourages visitors to actively participate in their own health by providing them with information about the plants they are considering using for therapeutic purposes. Below are some of the importance of identifying and labeling plants:

(a) **Enhancing Educational Opportunities**

The labeling of plants along healing paths is a great way to teach tourists about the medicinal properties of the area's flora. Educating tourists about the healing power of plants through their common and scientific names, as well as their traditional and therapeutic uses, is important [201]. The educational materials help people feel more connected to the natural world and develop an appreciation for the variety of life they'll encounter on their hike.

(b) **Ensuring Safe and Responsible Use**

The incorrect usage of hazardous or harmful plants can be avoided with proper plant identification. Visitors can reliably identify and avoid potentially toxic species with the help of clear and trustworthy plant labels [135]. By knowing this, you can avoid any potential health problems associated with misusing therapeutic plants.

(c) **Increasing the Depth of the Healing Process**

A more holistic and transforming healing experience is provided for guests by correctly identified medicinal plants. The healing benefits of the plants can really sink in as people go along the trail and experience them with their labels [202]. Accurate information fosters faith in the restorative power of nature, elevating the quality of one's experience.

(d) **Facilitating Individualized Instruction**

The ability to study and explore on one's own is enhanced by healing paths that feature clearly labeled therapeutic plants. With the information provided throughout the path, visitors can tailor their experience based on their own needs or areas of interest [203]. Visitors are empowered to take charge of their health and recovery by providing them with the means to do so.

(e) **Encouraging Respect for Nature**

Labelling plants helps spread an attitude of gratitude toward nature and the resources it provides. Visitors who are educated about the plants' historical and cultural significance are more likely to value the environment for what it contributes to human health and happiness [204]. This respect calls for eco-friendly, low-impact behavior on the healing trail.

9.2 Plant Identification Techniques in Healing Trails

The correct identification of plants is essential if tourists are to benefit from their curative effects. In healing trails, which place an emphasis on learning about and connecting with nature, visitors can learn more about local plant life by using a variety of plant identification methods. Some of these methods include the following:

(a) **Field Guides and Reference Books**

The plants used in healing trails can be identified with the use of field guides and other reference materials. Numerous plant species have been profiled in these books, along with their habitats, features, and medicinal uses [205]. Improve your plant identification skills and your appreciation for the local ecosystem by consulting a regional flora or medicinal plants field guide.

(b) **Herbaria and Botanic Gardens**

Visitors to botanical gardens and herbaria can examine the unique characteristics of plants in close proximity. Learning by doing and side-by-side species comparisons are only two of the many benefits of visiting a botanical garden [206]. Herbaria are great for research and fact-checking since they store preserved plant specimens.

(c) **Professional Guided Walks**

Visitors can gain first-hand experience with plant identification on guided walks conducted by botanists, herbalists, or expert naturalists [207]. These professionals can impart their extensive understanding of medicinal plants, highlight key characteristics, and provide direction for the responsible and secure identification of plants. Visitors can learn more and feel more connected to the natural world on walks led by experts.

(d) **Digital and Mobile Platforms and Applications**

Thanks to digital resources and application development, plant identification has become more convenient for the general public. Numerous smart phone programs employ neural networks for image recognition to determine the species of a plant from a photograph the user has taken [208]. Accessing information about a plant's medical characteristics and historic applications is a common feature of these apps.

(e) **Training Sessions on Plant Recognition**

Visitors can engage in hands-on learning during plant identification seminars hosted by healing path managers and local experts. Activities such as collecting botanical specimens, consulting field guides, and honing identification abilities are often incorporated into workshops [167]. Participating in such programs gives guests more experience in recognizing therapeutic plants on their own.

(f) **Citizen Science Projects, Number**

Visitors are encouraged to participate in plant identification attempts through citizen science activities. Scientists and conservationists can learn a lot about the distribution and presence of plants along healing paths if they get the public involved in data gathering [209]. Both the scientific community and the healing trail experience benefit from these kinds of activities.

(g) **Working with People Who Already Have the Knowledge**

Cooperation with local knowledge holders is crucial for healing paths situated in areas inhabited by indigenous communities. Native peoples have been keeping track of the medicinal and ecological value of local plants for decades [210]. Engaging with indigenous knowledge in a respectful manner promotes cross-cultural understanding and deepens insight into the practice of plant identification.

9.3 Ethical Foraging Practices in Healing Trails

For sustainable usage of medicinal plants and to protect ecological balance, ethical foraging methods are crucial along healing pathways. Responsible foraging methods are essential in ensuring that medicinal plants will be available for future generations as healing trails continue to attract people looking to experience the healing effects of nature. Ethical foraging guidelines and principles that visitors should follow when interacting with therapeutic plants include the following:

(i) **Sustainability and Biodiversity Conservation**

The sustainability of medicinal plant populations is given top priority in ethical foraging techniques. It's important for foragers to respect the plants' normal growth cycles and refrain from taking too much from them [211]. Visitors can help preserve plant diversity and maintain the long-term availability of these resources by taking only what is necessary and leaving a great deal of plants alone.

(ii) **Harvesting with Care**

Ethical foragers take great care to protect both the plant and its natural habitat when they gather their supplies. To protect the plant and its environment, they are careful not to pull it out by its roots [212]. Selective harvesting promotes plant health and growth by allowing plants to self-renew and spread.

(iii) **Respect for Cultural and Indigenous Knowledge**

Paths to health tend to pass through areas where there is a wealth of traditional and local knowledge about the therapeutic properties of plants. Foragers who operate ethically take into account the customs and expertise of the local population [210]. The people do not use any flora considered sacred or culturally significant without first obtaining permission from the local indigenous population.

(iv) **Avoiding Endangered Species**

Plants that are endangered or protected by conservation regulations should never be taken from the wild [147, 213]. It is important for foragers to be informed of the conservation status of indigenous plants and to avoid taking any endangered or threatened varieties.

(v) **Controlling Invasive Species**

Ethical foraging guidelines may inadvertently promote the collection of noxious weeds. Harvesting invasive species for medical use is one way to limit their spread, which can be damaging to native ecosystems [214]. To avoid unintentionally aiding the spread of invasive species, foragers should use prudence.

(vi) **Plant Propagation and Care**

When it comes to medicinal plants, ethical foraging also includes growing them from seed or cuttings [215]. If more people grew their own medicine, it would put less of a strain on wild species while still providing a steady supply.

(vii) **Adopting the "No Trace" Principle**

Ethical foragers must adhere strictly to the "Leave No Trace" code of conduct. It is recommended that foragers leave the place as they found it and make as little of an influence as possible [216]. The natural integrity of the healing trail will be preserved if visitors refrain from trampling plants and harming wildlife habitats.

10 Healing Trail Design and Landscaping

Healing paths can have positive effects on visitors' bodies, minds, and spirits depending on how they've been planned and landscaped. Creating a deep connection with nature, relaxation, and healing, a well-designed healing trail provides a harmonic and visually beautiful setting. In order to maximize the therapeutic effects of healing trails, this chapter delves into a number of design considerations, including trail layout, landscaping options, and the strategic use of medicinal plants.

10.1 Healing Trail Design

The effectiveness and pleasantness of a healing trail depend heavily on its design. Accessibility, aesthetics, and the natural flow of the landscape are all factors that should be considered when designing a trail. Trail design factors to think about include:

(a) **Availability and Acceptance**

To ensure that individuals of all abilities can benefit from nature's healing powers, it is crucial to develop a healing trail that is accessible to all. Wheelchair users and anyone with mobility issues should be given special consideration in the trail's layout. Paths should be large and flat or have a gentle incline so that people may easily navigate them [217].

(b) **Circular Versus Linear Paths**

The layout of healing trails can take the form of either a loop or a straight path. Hikers may get that same sense of accomplishment without having to retrace their steps on loop trails. In order to provide visitors with a wide range of experiences, many trails are now being designed as loops [218]. Linear trails, on the other hand, provide a continuous route across the natural landscape to designated destinations like lookout sites or unique geological formations.

(c) **Integration of Rest Areas**

The walk features a number of carefully located benches where hikers may sit back, relax, and take in the scenery. Seating, picnic tables, and naturally looking canopies are all appropriate amenities for rest stops [219]. Healing is aided by the opportunity for introspection and contemplation provided by such settings.

(d) **Directional and Interpretive Signage**

The educational value of the healing trail can be greatly improved by installing clear and informative interpretive signage at key locations along the path. Explanations of the area's geology, wildlife, and human history can all be included on signs. Trail users benefit from navigational signs because they make it easier for them to get around and learn more about the trail's layout and major features [220].

10.2 Landscaping Choices for Healing Trails

The mood and feel of a healing trail greatly depends on the landscaping that is used. The healing potential of the trail is boosted by the careful design of its surroundings:

(a) **Organic Components**

The design of the healing route is based on preserving and highlighting natural features, such as trees, bushes, and rock formations that are indigenous to the area. Genuineness and a sense of oneness with nature are provided by materials taken from nature [221]. Also crucial to local ecosystems and biodiversity, these components are often overlooked.

(b) **Water Attractions**

Small streams, ponds, or waterfalls might be incorporated into the healing route to provide a meditative and relaxing atmosphere. The soothing sound of water flowing has been shown to have a calming impact on visitors (Berman et al. 2020). Wildlife can be attracted to water features, adding to the whole natural experience.

(c) **Landscaping with Native Plants**

Landscaping the pathway with native plants helps sustain biodiversity in the area and makes the path blend in with its surroundings. There is less need for upkeep and supplies when using native plants because they are already accustomed to the weather and soil [167].

(d) **Changes with the Seasons**

The dynamic beauty of nature is accentuated by the healing trail's design, which takes into account seasonal changes in plant life and natural events. A greater understanding for nature's cyclical processes can be developed through witnessing the yearly transformation of the landscape as leaves turn, flowers blossom, and animals migrates.

10.3 Strategic Planting of Medicinal Plants

The therapeutic value of an area can be amplified via the strategic placement of medicinal plants along healing routes. The following factors should be taken into account when deciding where to strategically position these plants:

(a) **Naturally Occurring Medicinal Plants**

The design of a healing trail should prioritize the use of native and indigenous medicinal plant species whenever possible. Plants that are indigenous to an area have a greater chance of surviving and thriving there [167]. According to Giampiccoli and Kalis [222], indigenous plants and animals have cultural relevance because they introduce tourists to local traditions and knowledge.

(b) **Gardens for Medicinal and Educational Plants**

Visitors can learn more about the medical benefits of plants by visiting gardens or educational spaces dedicated to them [205]. A plant's historical applications, therapeutic properties, and any necessary precautions can all be communicated through informative signage.

(c) **Classification Based on Medicinal Values**

By grouping medicinal plants together according to their healing capabilities, the trail becomes a resource for exploring a variety of health-related topics [205]. The educational value of the trail is increased, and visitors are encouraged to focus on specific health concerns, when plants with similar healing benefits are grouped together.

(d) **Creation of Sensory Gardens**

Healing paths can include sensory gardens, which are landscaped with a wide range of plants chosen for their ability to evoke a range of sensory experiences. Aromatic plants like lavender and rosemary added to a space can create a peaceful and energizing atmosphere [223].

11 Healing Trail Certification and Quality Standards

Authenticity, safety, and efficacy of healing trails and medicinal plant walks must be guaranteed by standardized processes and quality assurance as their popularity grows. Connecting with nature, experiencing its therapeutic advantages, and learning about medicinal plants are all possible through healing paths. It is critical to create certification systems and quality criteria for healing trail offers to ensure the continued credibility of these services and the safety of trail users. Focusing on authenticity, sustainability, safety, and educational benefits, this chapter investigates the potential implementation of such certification schemes and quality criteria for healing trails with medicinal plant walks. Furthermore, the identification, isolation, and purification of the active compounds that makes the plants possesses specific therapeutic potentials is also key in the certification and quality standard analysis [224–235].

11.1 Ensuring Credibility and Ethical Practices

(a) **Professional Guidance**

Expert review should be part of a certification process for healing trails [222] to verify that trails are run ethically, that proper criteria are followed for medicinal plant use, and that the cultural relevance of indigenous medicinal knowledge is honored. The fields of ethnobotany, traditional medicine, and ecotourism all have experts who can contribute to the development of these guidelines.

(b) **Indigenous Community Participation**

It is crucial to include local communities in the certification process in areas where there is indigenous knowledge of medicinal plants. Traditional knowledge is better protected, respectful customs are maintained, and tourists have a more meaningful and meaningful encounter with indigenous peoples when they are involved [236].

(c) **Validating Medicinal Plant Data**

Healing trails may be required by certification programs to include trustworthy information about the therapeutic plants along the trail. It is important that visitors receive accurate educational content, so it is important to verify plant identification, traditional applications, and safety precautions.

(d) **Plant Source Documentation**

In order to meet certification standards, it may be necessary to provide proof of where the medicinal plants were harvested along the path. This paperwork guarantees that plants were harvested in a way that didn't impact natural populations [237].

11.2 Sustainability and Risk Management in Healing Trails

(a) **Assessing Risks and Taking Precautions**

Certification standards for healing trails should center on safety first and foremost. Trail designers and guides can benefit from a thorough understanding of potential dangers thanks to a hazard assessment, which may include the identification of plants that could be toxic or hazardous. Clear warnings and signage are examples of mitigation actions that can be used to protect tourists [238].

(b) **Methods of Sustainable Harvesting**

Sustainable methods of medicinal plant harvesting can be encouraged through certification schemes. Selective harvesting and culture are examples of responsible harvesting methods that can be used on trails without severely harming wild populations [239].

(c) **Assessment of Environmental Impact**

An environmental impact assessment may be required for certification if it is deemed necessary to protect the natural habitat of the healing trail. This report takes into account the trail's possible effects on the surrounding ecology and suggests ways to lessen those problems.

(d) **First Aid and Emergency Preparedness**

Healing trails that want to be certified may be required to have proper first aid equipment and emergency procedures in place. Visitor security can be improved by providing first aid training for guides and establishing secure lines of communication with emergency services.

11.3 Instructional Material and Interpretation in Healing Trails

(a) **Professional Tour Guides**

Accredited guides with knowledge of botany, ethnobotany, or traditional medicine may be required by certification programs for healing trails. It is imperative that people have access to reliable information on medicinal plants, their applications, and their cultural value, and guides play a pivotal role in this regard [211].

(b) **Cultural Relevance Interpretation**

Cultural interpretation of medicinal plants is a top priority along healing routes that pass through areas with significant indigenous history and tradition. This method promotes appreciation for indigenous wisdom and facilitates communication between tourists and locals [236].

(c) **Signage and Resources for Interpretation**

Visitors' knowledge of medicinal plants and their therapeutic properties is enhanced by the healing trail's well-designed interpretive signage and educational materials. The reliability and precision of these resources can be specified by means of certification standards.

(d) **Instructional Seminars and Courses**

Healing trails can be encouraged to host workshops and programs on medicinal plants and traditional healing modalities if they are certified to do so. Visitors can walk away from a workshop with practical skills they can use immediately [219].

12 Conclusion

The concept of healing trails and incorporating medicinal plant walks into recreational development has developed as a strong and transforming approach to holistic well-being. Throughout this extensive debate, we have covered the different features of healing trails, from their historical emergence to their incorporation into urban green spaces and parks. We have delved into the cultural legacy and traditional medicinal practices that infuse these routes with authenticity and meaning. Healing paths offer an unmatched opportunity for individuals to bond with nature, experience the therapeutic advantages of natural habitats, and receive insights into the traditional knowledge of medicinal plants. The merging of cultural heritage and traditional medicine not only encourages respect for varied traditions but also enhances the relationships between individuals and their natural surroundings.

As we explore further the area of ecotherapy and complementary medicine, the potential of healing trails to promote mental health, reduce stress, and enhance overall well-being becomes clear. Specific plant genera with calming or mood-lifting effects further show the deep impact of nature on human emotions and mental states. However, as healing paths gain popularity, it becomes vital to address the concerns of accessibility, inclusion, and ethical harvesting. By creating certification procedures and quality standards, we can ensure that healing paths preserve their originality, emphasize safety, and safeguard the ecosystem for future generations.

S. C. Izah et al. (eds.), *Herbal Medicine Phytochemistry*, Reference Series in Phytochemistry, https://doi.org/10.1007/978-3-031-43199-9_70

Abstract

Herbal medicine, deeply rooted in tradition, emphasizes locally sourced, renewable resources and is crucial in preserving cultural heritage. Technology has expanded its reach globally and encouraged inclusivity. Phytochemistry enhances the effectiveness of herbal treatments by identifying bioactive compounds, understanding their mechanisms, and ensuring product quality. The convergence of technology and tradition has far-reaching implications, promoting innovation, preserving heritage, and affecting various aspects of life. Artificial intelligence (AI) supplements conventional medicine without replacing it, enhancing accuracy, accessibility, and results. AI supports individualized therapy recommendations, predictive analytics, research, and diagnosis accuracy. It aids in herbal medicine development, extends healthcare access, and empowers patients. However, integrating AI into traditional medicine poses challenges such as data privacy, ethical dilemmas, and cultural value preservation. Overcoming generational technology gaps is vital. Successful integration addresses issues like data quality, regulatory compliance, resistance to adoption, risk of overreliance, cost, education, training, liability, and patient trust. This chapter advocates for AI integration into traditional medicine, which offers numerous benefits, including enhanced diagnosis, personalized treatment, research support, and patient empowerment. Overcoming the challenges is essential to fully leveraging this synergy, ensuring the advancement of healthcare while preserving cultural traditions and values.

AI	Artificial intelligence
TCM	Traditional Chinese medicine

1 Introduction

In many parts of the world, people have long relied on treatments and therapies that have their origins in traditional medicine. Traditional medicine, which is defined by methods that have been passed down through generations and refined over ages, has shown consistent effectiveness across a wide range of health concerns [9, 52]. Presently, there is a growing need to improve traditional medicine accuracy, broaden its availability, and streamline its incorporation into cutting-edge healthcare infrastructure. To meet this challenge, the incorporation of artificial intelligence (AI) stands out as a promising path since it can help bridge the gap between traditional medicine and cutting-edge medical advances. Combining AI with conventional medicine is a giant step forward in improving patient care [20, 49].

Healthcare is no exception to the impressive advancements being made in a variety of fields by AI, a branch of computer science that aims to build intelligent robots that are capable of carrying out activities that traditionally require human intelligence [5]. Ayurveda, herbal medicine, acupuncture, and traditional Chinese medicine (TCM), all of which have their own distinct beliefs and practices, are just a few of the therapeutic modalities that fall under the umbrella of traditional medicine [28, 50–52]. The addition of AI to these established methods has the potential to improve patient care by increasing the precision of diagnoses, the effectiveness of therapies, and, eventually, their overall health. Traditional medicine has played a significant role in delivering healthcare treatments that have been firmly ingrained in the history and cultures of many different countries for ages. This broad field includes a variety of therapeutic modalities, including manual therapies, spiritual practices, herbal cures, and energy-based therapies. These techniques have been developed as a result of careful observation, empirical information that has been passed down through the years, and practical experience [19, 47].

TCM, a long-standing tradition dating back more than two millennia, serves as one example. TCM includes a variety of therapeutic methods, such as acupuncture, herbal medicine, nutritional advice, and mind-body practices like Tai Chi and Qigong [80]. This all-encompassing approach has helped treat a variety of health problems and promote general well-being. Similar to this, restoring harmony and balance between the body, mind, and spirit is a major focus of the traditional Indian medicinal system known as Ayurveda [23–29, 52]. To improve health and avoid disease, this holistic approach makes use of nutritional advice, yoga, meditation, and herbal medicines. These venerable belief systems have a profound grasp of the complicated relationships that exist between the human body and the natural environment, highlighting how crucial it is to achieve and maintain equilibrium to maintain good health. Due to the potential role of AI in traditional medical procedures and beliefs, it is essential to consider how AI may improve the precision and efficiency of conventional treatments, modernize their delivery, and solve enduring problems [60, 81].

The ethical issues and potential difficulties associated with the integration of AI into conventional healthcare systems are equally important. The importance of conserving traditional medicine through culture and historical diversity while utilizing AI could ensure that these age-old therapeutic techniques continue to make a substantial contribution to global healthcare in the twenty-first century and beyond. AI and conventional medicine working together may have the potential to improve healthcare outcomes, increase access to high-quality care, and combine the best aspects of both worlds: conventional medicine and cutting-edge technology. This chapter comprehensively explores the revolutionary effects of AI on conventional medical procedures by emphasizing the complex interactions between tried-and-true treatment modalities and AI-driven innovations. Importantly, this is because AI plays a complementary function in conventional medicine, enhancing rather than replacing the skills of traditional practitioners [18, 63, 84].

2 Exploring the Significance of Herbal Medicine in Traditional Practices and the Role of Phytochemistry in Efficacy

Herbal medicine, phytotherapy, or plant medicine is a crucial component of traditional medicine throughout the world [2, 3, 34, 43]. It uses a variety of plant-derived substances, including those found in the roots, leaves, stems, flowers, and fruits, to prevent, identify, and cure a wide range of medical diseases [32, 40–42, 72, 73, 83]. Herbal medicine is still a key part of conventional medicine since it provides important knowledge about holistic approaches to health, the preservation of cultural heritage, and natural cures. As it completes and expands the variety of therapeutic options accessible to people and communities around the world, its enduring relevance is obvious [81, 84]. Table 1 lists the historical importance, cultural relevance, holistic approach, sustainable and local resources, complementary care, preservation of cultural legacy, and accessibility of herbal medicine in traditional practices [8, 30, 44, 50–52].

Therefore, understanding the crucial role of phytochemistry in the effectiveness of herbal medicine is vital for comprehending how medicinal plants function and their potential health benefits [15–17, 31, 33, 53–56]. Phytochemistry is a subfield of chemistry that focuses on investigating the chemical constituents within plants, detailing their structure, composition, and functions. The significant contributions

Table 1 Role of herbal medicine in traditional practices

Aspect	Roles
Historical significance	Herbal medicine, practiced for centuries, holds historical importance. Ancient societies worldwide, including China, India, and indigenous communities, have extensive knowledge of herbal remedies
Cultural relevance	Herbal medicine is deeply ingrained in cultural practices, beliefs, and traditions. Herbal medicine practice is a vital part of cultural heritage, expressing community identity, often passed down through generations
Holistic approach	Traditional healing systems, like herbal medicine, take a holistic approach. They address physical symptoms and the interplay of mind, body, and spirit, promoting overall well-being
Sustainable and local resources	Traditional medicine, such as herbal remedies, values local, sustainable resources. This aligns with modern environmental goals, supporting self-sufficiency and minimizing environmental impact
Complementary care	Herbal medicine complements modern healthcare, providing additional treatment options for a wide range of diseases. Patients can choose therapies that align with their cultural backgrounds
Cultural heritage preservation	Herbal medicine plays a vital role in preserving cultural traditions and passing regional knowledge to future generations. Efforts like digitization and collaboration with indigenous groups are crucial
Global accessibility	Advancements in technology have enabled the worldwide dissemination of knowledge about herbal medicine. This fosters inclusivity, making herbal remedies more accessible and bridging cultural divides

of phytochemistry to the efficacy of herbal therapy include the identification of bioactive compounds, understanding mechanisms of action, quality control, and standardization, optimizing extraction techniques, safety and toxicology, compound synergy, bioavailability and pharmacokinetics, drug-plant interactions, ethnopharmacology, and evidence-based medicine [69, 78] (Table 2).

Therefore, phytochemistry is integral to herbal medicine research and practice. It enhances the understanding of how medicinal plants work, supports quality control, ensures safety, and promotes the integration of herbal medicine into evidence-based healthcare. The knowledge of the chemical composition of medicinal plants is central to harnessing their full therapeutic potential [8, 9, 24, 26, 27, 29].

Table 2 Significant contributions of phytochemistry to the efficacy of herbal therapy

Aspect	Significant contributions of phytochemistry to the efficacy of herbal therapy
Identification of bioactive compounds	Phytochemistry is crucial for identifying and characterizing bioactive compounds in medicinal plants, including alkaloids, flavonoids, terpenes, glycosides, tannins, saponins, phenolic compounds, etc. essential for understanding therapeutic properties
Understanding mechanisms of action	Analyzing phytochemical composition helps researchers understand how medicinal plants exert therapeutic effects. This understanding is vital for defining unique mechanisms of action
Quality control and standardization	Phytochemical analysis ensures the quality and standardization of herbal products, maintaining consistent levels of active compounds for predictable and reproducible effects
Optimizing extraction techniques	Knowledge of phytochemistry guides the selection of appropriate extraction methods to efficiently isolate bioactive compounds, maximizing yields and therapeutic potential
Safety and toxicology	Phytochemistry identifies potentially toxic compounds in medicinal plants, essential for safety assessments and establishing proper dosage guidelines to prevent adverse effects
Compound synergy	Medicinal plants contain multiple bioactive compounds that work synergistically for therapeutic effects. A deeper understanding of phytochemistry helps identify potential synergies and optimize formulations
Bioavailability and pharmacokinetics	Phytochemistry contributes to knowledge about how the body absorbs, distributes, metabolizes, and eliminates bioactive substances from medicinal plants, aiding in developing high bioavailability formulations
Drug-plant interactions	Some bioactive compounds in medicinal plants may interact with pharmaceutical medications. Phytochemical research helps identify potential interactions for safe and effective care
Ethnopharmacology	Phytochemistry aligns with ethnopharmacological research, combining traditional and indigenous knowledge of plant-based medicine with a focus on cultural and phytochemical insights
Evidence-based medicine	Phytochemistry contributes to the evidence base for herbal therapy. Scientific studies examining the phytochemical profile of medicinal plants provide essential data supporting their use in healthcare

3 The Nexus of Tradition and Technology

The convergence of technological advancement and cultural customs has become a subject of intense interest and a crucial aspect of contemporary life. Progress and innovation are often linked with technological advancement; tradition signifies the timeless principles and customs that connect us to our cultural origins. These divergent forces create a dynamic space where the past and future intersect, fostering innovation, the preservation of traditions, and exact change.

The rapid evolution of technology has brought profound changes in how we work, communicate, and live. It has enabled us to transcend geographical boundaries, disseminate knowledge at unprecedented rates, and enhance the quality of life through medical breakthroughs and sustainable inventions. Humanity has propelled itself into a technology-driven era; therefore, concerning tradition, striving to strike a balance between the efficiencies offered by technology and the depth of experience offered by tradition [75].

One domain where this synergy is particularly evident is in the realm of culture and the arts. Modern technology has brought new life into time-honored art forms such as music, dance, and storytelling [21]. Streaming services have made it possible for people worldwide to access traditional melodies once confined to isolated communities. Artists blend traditional techniques with modern digital tools to create compelling experiences across various mediums [57]. The advancements in virtual reality and augmented reality have opened up new avenues for cultural preservation, allowing individuals to explore heritage sites and artifacts from the comfort of their homes.

Education is another significant arena where this convergence plays a pivotal role. Online learning platforms have made the dissemination of knowledge, both ancient and modern, a global phenomenon, reaching the farthest corners of the world [77]. Students now have access to the teachings of ancient philosophers alongside the latest scientific discoveries. Traditional classroom learning coexists with innovative educational approaches enabled by technological progress.

The corporate world, too, has embraced this nexus by fostering a corporate culture that respects tradition while embracing innovation, creating a win-win situation for all. Many businesses recognize the importance of diversity and inclusivity, which often involves respecting employees' cultural backgrounds and traditions [68]. Technology is harnessed to create flexible work environments, enabling individuals to uphold religious customs or cultural practices while maintaining productivity.

In healthcare, the nexus has a significant impact as well. Traditional and modern forms of medicine are integrated to provide holistic healthcare solutions [46]. Cutting-edge research and diagnostic methods are used to analyze and enhance traditional remedies [1]. This harmonious blend of antiquity and modernity offers a more comprehensive approach to healthcare, acknowledging the significance of religious and cultural observances in overall well-being.

Nevertheless, the nexus is not without challenges. The rapid pace of technological advancement can render traditional practices obsolete, and generational disparities in

Table 3 Overview of the convergence of technology and tradition

Aspect	The convergence of technology and tradition
Convergence significance	The fusion of technology and tradition is of intense interest and a critical aspect of modern life. It bridges progress and innovation with timeless cultural principles, fostering innovation, tradition preservation, and transformative change
Technological impact	Rapid technological evolution transforms work, communication, and daily life, breaking geographical barriers, disseminating knowledge, enhancing healthcare, and igniting sustainability
Cultural and artistic revival	Technology revitalizes traditional cultural forms such as music, dance, and storytelling, granting global access to heritage, and merging conventional techniques with digital tools for multimedia experiences
Educational transformation	Online platforms democratize knowledge, offering ancient wisdom alongside cutting-edge discoveries, while blending traditional and innovative educational methods
Corporate embrace of tradition	Businesses promote diversity and inclusivity, respecting employees' cultural backgrounds. Technology facilitates flexible work settings that honor cultural practices
Holistic healthcare integration	Traditional and modern medicine harmonize, employing advanced research and diagnostics to enhance traditional remedies, and acknowledge cultural and religious significance in healthcare
Challenges and preservation	Rapid technological advancement risks erasing traditions, and generational gaps in tech adoption may undermine cultural knowledge. Navigating the intersection requires preserving wisdom while harnessing technology's power

technology adoption can lead to divisions within societies, potentially eroding cultural knowledge and values [6]. It is crucial to navigate this intersection thoughtfully, preserving traditional wisdom while harnessing the power of technology.

Table 3 shows the overview of the convergence of technology and tradition. The intersection of tradition and technology is a dynamic space where the past and future coexist harmoniously. It serves as a bridge between generations, a driving force in preserving cultural traditions, and a wellspring of boundless creative potential. This harmony underscores our capacity to adapt and evolve, maintaining a connection to our heritage while embracing the opportunities of the digital age. To navigate this intricate crossroads successfully, we must continue to find ways to honor tradition, harness technology for the greater good, and ensure that progress does not come at the expense of our cultural and historical identity.

4 The Complementary Role of Artificial Intelligence in Traditional Medicine Practices

Traditional medicine practices are increasingly recognizing the benefits of integrating AI into their operations within the ever-evolving healthcare industry. This transition does not involve replacing traditional practitioners with new ones, rather it's about enhancing the precision, accessibility, and outcomes of traditional therapeutic systems by complementing the expertise of traditional practitioners [4, 67]. In traditional medicine, AI could play a complementary role, bolstering the capabilities of traditional healers in various ways. This comprehensive analysis highlights the significant and symbiotic impact of AI on advancing traditional medicine practices (Table 4). It involves envisioning a promising future where the preservation of cultural heritage and the integration of cutting-edge technology coexist harmoniously, advancing healthcare and enhancing patient well-being through the collaboration of artificial intelligence and traditional healing systems [5, 12, 59].

Table 4 Benefits of artificial intelligence in traditional medical practices presented in a tabular form

AI application	Benefits
Enhanced diagnosis accuracy	AI could improve the precision of traditional diagnostic methods by analyzing patient records and medical images, enabling early disease detection
Personalized therapy recommendations	AI can use patient-specific data to create tailored treatment plans based on medical history, genetics, and lifestyle, resulting in more effective and precise therapies
Predictive analytics	Due to the predictive capabilities of AI, it can help clinicians foresee patient outcomes and treatment responses through predictive analytics, allowing for timely adjustments and improved patient care
Medical research support	Due to AI's speed, it can process data rapidly, thereby aiding in medical research by identifying patterns, exploring new treatment options, and enhancing traditional herbal medicines
Continuous patient monitoring and follow-up	AI-powered systems can continually monitor patient health, issuing alerts for deviations, enabling prompt interventions, and improving patient outcomes
Expanded reach in underserved areas	AI can act as decision support for traditional practitioners, extending healthcare services to remote areas and optimizing resources, particularly in regions with limited healthcare access
Herbal medicine development	AI can analyze extensive data on plant characteristics and bioactive compounds, enhancing traditional herbal medicine by determining the most effective treatments
Facilitating telemedicine	AI can enable remote consultations, simplifying access to healthcare for patients in rural or underserved areas and facilitating follow-up care
Streamlined administrative tasks	AI can automate administrative duties, such as appointment scheduling and patient information management, improving efficiency, and allowing practitioners to focus on patient care
Reducing human errors	AI systems are less error-prone, resulting in more reliable diagnoses and treatments, ultimately enhancing patient safety and reducing incorrect diagnoses
Empowering patients	AI can provide patients with access to health data and educational resources, enabling informed decision-making and fostering better collaboration with healthcare providers
Continuous learning and adaptation	AI can continually learn and adapt to evolving medical knowledge, ensuring traditional practices stay current with the latest advancements in healthcare

5 Utilizing Artificial Intelligence for Enhanced Diagnostics

The field of medical diagnosis may undergone a profound transformation with the advent of AI. AI systems, powered by intricate algorithms and machine learning, can analyze extensive medical databases, encompassing patient records and medical imagery, with unparalleled precision and speed [62, 70]. This innovation tends to bring forth several significant advantages as shown in Table 5.

Traditional medicine encompasses a rich reservoir of knowledge and practices passed down through generations. It often encompasses herbal remedies, dietary modifications, and holistic approaches to healing. Traditional medicine presents several advantages when harmonized with AI-enhanced diagnostics (Table 6).

The integration of AI diagnostics with conventional medical practices holds immense promise. However, this is not without its challenges. Rapid technological advancements have the potential to render longstanding practices obsolete, and the rate at which different generations embrace new technologies may vary. Successfully

Table 5 Benefits of artificial intelligence for enhanced diagnostics

Aspect	Benefits of artificial intelligence for enhanced diagnostics
Improved accuracy	AI can assist in precise and timely disease diagnosis by analyzing patient records and medical images and identifying subtle patterns and anomalies for early detection
Personalized diagnosis	AI can consider individual patient data, including genetics and medical history, to provide tailored diagnoses, enhancing accuracy, and ensuring suitable treatment strategies
Predictive analytics	Due to the predictive capabilities of AI, it can enable healthcare professionals to anticipate patient outcomes and treatment responses by analyzing extensive datasets, aiding informed decision-making

Table 6 Synergizing traditional medicine with AI-enhanced diagnostics: Advantages and opportunities

Aspect	Traditional medicine with AI-enhanced diagnostics; synergy perspective
Holistic healthcare solutions	Traditional medicine focuses on holistic patient care, considering environmental, emotional, and physiological factors. AI-enhanced diagnostics enable tailored treatment plans based on individual medical histories and lifestyles
Evidence-based traditional medicine	AI can play a pivotal role in scientifically validating traditional treatments by analyzing data on plant properties, bioactive substances, and their interactions with the human body. This enhances the credibility of traditional medicine
Remote healthcare services	AI-facilitated telemedicine can allow traditional medicine practitioners to consult with patients regardless of their location, particularly benefiting those in underserved or remote areas

navigating this convergence necessitates the thoughtful preservation of traditional wisdom while harnessing the power of technology for the healthcare sector for the greater good [48, 58].

6 The Ongoing Relevance of Traditional Medicine in the Modern Era

Traditional medicine has been a long-standing and crucial part of healthcare globally. It is rooted in centuries-old practices and frequently draws on cultural knowledge. It coexists and occasionally combines with traditional Western medicine in the modern period, presenting potential and difficulties for the field. Modern society still finds value in traditional medicine because of its cultural relevance, all-natural treatments, and sustainable practices [23, 25, 30]. As such, about 80% of the world's population still seeks treatment from traditional medicine practitioners [35–39]. Many of these people reside in rural areas in many developing nations. To guarantee the continued relevance and contributions of traditional medicine to the health and well-being of the world, its scientific confirmation and knowledge preservation are crucial. Traditional medical knowledge is well-positioned to make a lasting impact in today's healthcare landscape, which is increasingly focused on individualization and comprehensiveness.

6.1 The Significance of Traditional Medicine

Traditional medicine is deeply rooted in cultural identity and legacy, serving as a source of pride and a means of preserving ancestral values and wisdom passed down through generations. It often adopts a holistic approach, recognizing the interconnectedness of the mind, body, and spirit, thereby complementing Western medicine by addressing not only physical symptoms but also the mental, emotional, and spiritual well-being of patients. Additionally, traditional medical systems prioritize preventive care and advocate for a balanced lifestyle, making them particularly relevant in tackling modern health challenges like stress, obesity, and chronic diseases. Moreover, traditional medicine frequently relies on local and sustainable resources, aligning with contemporary sustainability goals and reducing its environmental impact while promoting self-sufficiency. Figure 1 summarizes the significance of traditional medicine.

6.2 Opportunities and Challenges of Traditional Medicine in the Modern World

Traditional medicine faces the pressing challenge of scientific validation to ensure the safety and effectiveness of its therapies, leading to an increasing collaboration between modern researchers and traditional healers [20, 45]. The regulation of

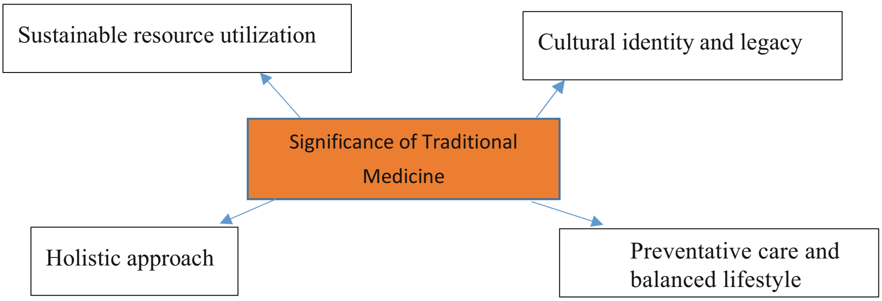

Fig. 1 The significance of traditional medicine

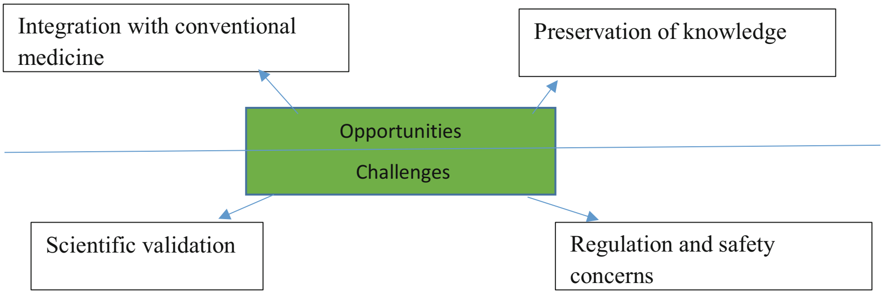

Fig. 2 Opportunities and challenges of traditional medicine in the modern world

traditional medical practices can be intricate, particularly when they involve potentially harmful or ethically questionable activities, with a strong focus on ensuring patient safety, prompting various nations to enact regulations for traditional medicine. Integrative medicine, which combines traditional and conventional approaches, is gaining prominence in modern healthcare, offering patients a more comprehensive and personalized approach to their well-being [13]. The preservation of traditional medical knowledge is of paramount importance, with ongoing initiatives utilizing digitization, training programs, and partnerships with indigenous communities to document and transmit this invaluable wisdom to future generations [22, 79]. Figure 2 summarizes the opportunities and challenges of traditional medicine in the modern world.

6.3 Case Studies in Modern Traditional Medicine

In India, Ayurveda, a traditional system of medicine, has evolved to offer contemporary services like personalized treatments, wellness retreats, and herbal products, earning international recognition for its holistic approach to health [14]. Similarly, TCM has become an integral part of healthcare in China and worldwide, combining acupuncture, herbal remedies, and lifestyle guidance, providing treatment options for various conditions, often used alongside Western medicine. Indigenous healing practices are also making strides, with indigenous communities striving to maintain their traditions while collaborating with modern healthcare providers [61]. These initiatives emphasize the cultural significance of these practices and their role in promoting community health.

7 Navigating the Ethical Challenges of AI Integration in Traditional Medical Practices

AI can potentially revolutionize the healthcare sector, including traditional medical practices. However, this transformation may bring many challenges and ethical considerations that must be carefully addressed. There are some of the essential concerns that need to be resolved when incorporating AI into traditional healing systems. These challenges and ethical dilemmas are pivotal for successfully integrating AI into traditional medicine and are summarized in Table 7.

Therefore, balancing the potential benefits of AI in traditional medicine with these challenges and ethical considerations is paramount. An ethical framework that prioritizes patient well-being, cultural sensitivity, and accountability is essential for the harmonious integration of AI into traditional healing systems. Addressing these issues ensures that AI positively contributes to preserving and advancing traditional medicine while upholding the highest standards of healthcare ethics [62, 67].

8 The Future of Traditional Medicine with Artificial Intelligence

The fusion of AI and traditional medical practices holds immense potential for advancing healthcare in the future. Traditional healing methods are on the brink of a profound transformation driven by the rapid progress of AI technologies. This section explores the potential impact, advantages, and challenges of integrating AI into traditional medicine, envisioning a future where time-honored wisdom harmoniously blends with cutting-edge technology [59, 66].

The promises of artificial intelligence in traditional medicine are as follows: enhanced diagnosis and treatment, accessibility and cultural preservation resource optimization, and environmental stewardship. AI algorithms can empower traditional practitioners by providing accurate diagnoses and personalized treatment plans, seamlessly integrating traditional knowledge with data-driven insights. This may result in a more comprehensive understanding of a patient's condition. The incorporation of AI will equip practitioners to make better-informed decisions, ultimately improving patient outcomes. AI-driven digital platforms and telemedicine solutions will enable the preservation of traditional healing methods, making them accessible to patients worldwide. Indigenous communities can connect with modern healthcare, preserving their rich traditions while extending medical assistance to

Table 7 Challenges and ethical considerations of AI integration in traditional medical practices

Challenges and ethical considerations	Ethical consideration
Data privacy and security: The challenge	It will be good to protect patients' right to confidentiality with strict data protection protocols and informed consent requirements
Cultural context and sensitivity: The challenge	AI developers should strive to incorporate cultural awareness in algorithms, with medical professionals offering context for culturally diverse patients
Excellence and personal responsibility: Problem	It will be good to incorporate accountability criteria that are vital to ensure responsibility for AI development and its outcomes in healthcare
Informed consent: The obstacle	It will be good for end users in the health and medical sector to ensure that patients fully understand AI use in treatment and its implications
Bias and fairness: The challenge	It will be good to do vigilant monitoring and audits when required to identify and rectify biases, ensuring equal care for all demographic groups
Compliance with regulations: Challenge	It will be good to develop and update regulations covering AI in traditional medicine, aligning with legal standards and the unique nature of traditional healing
Professional training: Challenge	It will be good for traditional medicine practitioners to have access to educational programs to effectively use AI, in other words to showcase their commitment to patient care
Transparency and explainability: Obstacle	It will be good to prioritize transparency and explainability in AI algorithms, allowing practitioners to comprehend and validate AI's decisions
Patient autonomy: Challenge	It will be good to ensure patients retain the final say in treatment choices, using AI as an informative tool rather than a decision-maker
Long-term impact: Challenge	It will be good to continuously evaluate and research AI to understand the long-term effects of AI on traditional medicine, enabling timely adjustments and improvements

remote regions. AI may facilitate the sustainable utilization of local resources in traditional medicine, aligning with contemporary environmental sustainability goals. This optimization ensures self-sufficiency and reduces the environmental impact of traditional practices [12, 63, 66].

Challenges and ethical considerations in the future of AI include data privacy and security, cultural context and sensitivity, accountability and quality assurance, bias and fairness, and informed consent. The application of AI requires the responsible handling of sensitive patient data, necessitating robust data protection measures and obtaining informed consent from patients. Upholding ethical standards is essential to safeguard patient privacy. Incorporating cultural context and awareness into AI algorithms is imperative to ensure respect for diverse cultural beliefs and practices. Medical professionals need to deliver care that is culturally sensitive, including the interpretation of AI-driven results [18, 48]. Ensuring AI algorithms' reliability and high quality prevents erroneous diagnoses and treatment recommendations.

Accountability standards need to be established to hold those involved in AI development and usage responsible for the outcomes of AI-assisted treatments. Patients should be made responsible for fully understanding the role of AI in their treatment and the potential consequences of providing informed consent. Medical practitioners may play a pivotal role in educating and informing patients about the integration of AI. AI systems may inherit biases from training data, potentially leading to unequal treatment and outcomes for different demographic groups. Ethical considerations necessitate continuous monitoring and correcting biases to ensure equitable and just care for all patients [4, 5, 70].

Despite the role of AI in more accurate diagnosis and treatment alongside preserving culturally significant procedures, it comes with ethical considerations, including accountability, cultural sensitivity, and data security. Therefore striking a balance between tradition and technology can shape a future where AI and traditional medicine collaborate to provide comprehensive and culturally sensitive healthcare solutions. Attempting to address these challenges, the incorporation of AI into traditional medicine can positively impact the well-being of individuals and communities, resulting in a harmonious fusion of traditional healing practices with state-of-the-art technological advancements [65, 81].

9 Preserving Cultural Heritage and Healing Wisdom: The Role of Herbal and Traditional Medicine

Herbal and traditional medicine, which are firmly entrenched in centuries-old customs and cultural knowledge, serve as both a vital steward of our cultural legacy and a priceless resource for complementary medical procedures. In-depth research on the value of traditional and herbal medicine in conserving cultural legacies and the priceless medical information passed down through the centuries is provided in this section. Table 4 provides a summary of the historical background and therapeutic knowledge of herbal and conventional medicine. Cultural identity is deeply linked with its use of herbal and traditional medicine, which reflects the values, beliefs, and knowledge that have been passed down through the years [20, 84]. These habits may serve as a source of cultural pride and a way to keep information about earlier behaviors and traditions alive. A holistic approach emphasizing the interdependence of the patient mind, body, and spirit is also frequently embraced by herbal and conventional therapies. According to cultural standards, this holistic approach takes into account the physical, mental, emotional, and spiritual wellness of the patient. Traditional medicine usually uses locally sourced, environmentally friendly resources, minimizing its detrimental environmental impact and encouraging self-sufficiency. Modern sustainability objectives are consistent with the emphasis on natural remedies [9, 23, 25–27, 29, 50, 51] (Table 8).

The function of herbal and traditional medicine in modern health is summarized in Table 9. Modern healthcare is complemented by herbal and traditional medicine in contemporary health by giving patients more options for treating a range of ailments.

Table 8 Cultural heritage and healing wisdom

Aspect	Cultural heritage and healing wisdom
Cultural significance	Herbal and traditional medicines are deeply entwined with cultural identity
	Reflect cultural values, beliefs, and ancestral knowledge
	Source of cultural pride and preservation of ancient customs
Healing from a holistic perspective	It embraces a holistic approach to health and well-being
	It emphasizes the interconnectedness of mind, body, and spirit
	It considers mental, emotional, and spiritual aspects alongside physical health
Sustainable healing and environmental responsibility	It relies on local, sustainable resources
	It reduces the negative impact on the environment
	It aligns with contemporary sustainability goals

Table 9 The role of herbal and traditional medicine in contemporary health

Aspect	Key points
Complementary care	Herbal and traditional medicine enhance modern healthcare
	It offers a wide range of additional treatment options
	The patients can choose therapies that align with cultural heritage and beliefs
Preservation of cultural traditions	It may play a vital role in preserving cultural practices and local knowledge
	It may ensure traditions remain relevant and continue for future generations
	Preservation efforts include digitization, educational programs, and collaboration
Global access and inclusivity	Technological advancements enable the global dissemination of traditional medicine
	It will enable greater accessibility to bridge cultural divides, making healing more inclusive

They provide a variety of therapeutic methods, enabling patients to select therapies that are compatible with their cultural background and worldview. To ensure that these traditions remain relevant, traditional medicine is essential for maintaining cultural practices and passing on regional expertise to future generations. The preservation depends on several initiatives, such as the digitalization of documents, the execution of educational initiatives, and joint initiatives with indigenous groups. By allowing the global distribution of traditional medicine knowledge via digital channels, technological improvements can promote inclusion on a global level. Traditional and herbal medicine are becoming more widely available, bridging cultural gaps and providing healing options to a global audience [8, 23, 29, 30, 50, 51, 71].

There are opportunities and challenges for herbal and traditional medicine in modern health (Fig. 1). Traditional medicine needs additional research to verify the efficacy and safety of its treatments because it lacks scientific confirmation. Collaborations between modern academics and conventional practitioners can close this gap. To ensure patient safety and the upkeep of moral norms, traditional and conventional therapies must be regulated. Nations' newly passed laws attempt to strike a balance between traditional values and the demands of the present. Integrative medicine mixes traditional and modern practices to offer complete healthcare solutions. Patients benefit from customized therapy solutions that take into account their cultural and medical needs. To successfully incorporate contemporary knowledge into their techniques, traditional practitioners might need further training. Their capacity to bridge the gap between conventional and modern medicine is improved by access to educational opportunities [7, 76].

Therefore, herbal medicine and traditional practices serve as essential custodians of cultural heritage, preserving healing wisdom and holistic approaches to well-being. As these practices evolve and integrate with modern healthcare, they offer diverse treatment alternatives while respecting cultural traditions. Collaboration between traditional and modern medicine is crucial for preserving and advancing healthcare practices that honor our heritage and contribute to the well-being of individuals and communities. With its millennia-old history, traditional medicine continues to enrich our understanding of health and healing [64, 74, 82].

10 Benefits and Challenges of Artificial Intelligence in Traditional Medicine Practices

Integrating AI in traditional medicine practices offers a range of potential benefits, which can significantly enhance the healthcare field. The key benefits are summarized in Table 10.

The integration of AI into traditional medicine practices presents several challenges that must be carefully addressed. These challenges encompass technical, ethical, and practical concerns. Table 11 summarizes the challenges of AI in herbal medicine practices.

Therefore, since AI offers numerous benefits in traditional medicine, addressing these challenges is crucial to ensure its successful integration while preserving the principles and ethics of traditional healthcare practices. Artificial intelligence has enormous and varied potential applications in traditional medical procedures. AI has the potential to completely transform conventional medicine by enhancing diagnosis and treatment, personalizing care, and overcoming resource limitations. However, it is crucial to go slowly, address moral issues, and make sure that AI augments rather than replaces the knowledge of practitioners of conventional medicine. When used appropriately, AI can be a useful tool for maintaining and improving the efficacy of conventional medical procedures [10, 11].

Table 10 Benefits of artificial intelligence in traditional medicine practices

Benefit	Benefits of artificial intelligence in traditional medicine practices
Enhanced diagnosis and disease detection	AI can analyze extensive data for accurate early disease detection, improving treatment success rates
Improved treatment recommendations	AI can assist in personalized treatment plans based on a patient's medical history, genetics, and lifestyle
Predictive analytics	AI can be used to predict patient outcomes, helping practitioners anticipate complications and adjust treatment plans
Data analysis and research	AI can aid in processing vast medical data, identifying trends, and enhancing herbal remedies
Patient monitoring and follow-up	AI-driven systems can continuously monitor patients, providing timely interventions and improving outcomes
Resource optimization	AI can extend healthcare services to underserved areas by providing decision support and remote consultations
Herbal medicine development	AI may identify effective herbal remedies through data analysis, promoting evidence-based herbal medicine
Telemedicine	AI facilitates remote consultations, benefiting patients in rural areas and supporting follow-up care
Efficiency and productivity	AI automates administrative tasks, streamlining workflow and allowing practitioners to focus on patient care
Reduced human error	AI systems reduce errors in procedures and diagnoses, enhancing reliability and patient safety
Patient empowerment	AI provides access to health data and educational resources, empowering patients to make informed decisions
Continuous learning and adaptation	AI continuously learns and adapts to evolving medical knowledge, keeping traditional medicine practices up-to-date

11 Conclusion

A turning point in healthcare will be reached when AI is integrated into conventional medical procedures. This will allow for the integration of cutting-edge technology with the wisdom of long-standing traditions. This paradigm shift could be made possible by the harmonic fusion of technology and tradition, forging a connection between development and cultural heritage. Beyond improving healthcare, this union may protect cultural traditions and knowledge, ensuring its applicability to coming generations. Traditional medicine has a long cultural and historical history and is firmly rooted in communities all around the world. It not only provides a wide range of culturally rich treatment alternatives, but it also enhances contemporary healthcare by adopting a holistic therapeutic philosophy and utilizing locally sourced, sustainable materials. The preservation of cultural heritage and the global transmission of traditional knowledge are essential components of this fusion of technology and tradition. Phytochemistry, which clarifies bioactive components and their modes of action and ensures quality control and standardization, is a major factor in the effectiveness of herbal therapy. It aids in safety and toxicological

Table 11 Challenges of artificial intelligence in traditional medicine practices

Challenge	Challenges of artificial intelligence in traditional medicine practices
Data privacy and security	Traditional medicine practices handle sensitive patient data. AI systems must ensure robust data protection and encryption to safeguard patient privacy. Compliance with data protection regulations may be crucial
Ethical dilemmas	AI in healthcare may raise ethical issues, such as the potential for bias in algorithms, data ownership, informed consent, and the ethical use of patient data. Traditional medicine must navigate these ethical commemorates
Integration with traditional practices	AI may need to complement, not replace, traditional medicine. Finding the right balance between AI and the human touch is a challenge
Quality of data	The effectiveness of AI may rely on the quality of the data it uses for training and analysis. Inaccurate or biased data can lead to incorrect diagnoses and recommendations. Traditional medicine needs to ensure data quality
Regulatory compliance	Healthcare regulations and standards are stringent. Therefore, AI systems in traditional medicine need to adhere to these standards, which can be complex and vary from region to region. Compliance is a critical challenge
Resistance to adoption	Traditional medicine practitioners may resist adopting AI, fearing a loss of professional autonomy or skills
Risk of overreliance	An overreliance on AI for diagnosis and treatment decisions can be risky. There is a risk of overlooking critical clinical judgment. Therefore, striking the right balance between AI and human expertise is challenging
Cost and infrastructure	Implementing AI systems can be expensive, and not all traditional medicine practices may have the financial resources to invest in the necessary infrastructure and training. Cost-effectiveness is often a concern
Training and education	Traditional medicine practitioners need training to use AI tools effectively. Bridging the knowledge gap and ensuring practitioners are proficient in AI technologies is a significant challenge
Liability and malpractice	Determining liability in case of AI-related errors or malpractice can be complex. Establishing clear legal frameworks and accountability standards for AI use in traditional medicine is challenging
Patient trust and communication	Patients need to trust and understand the AI systems used in their healthcare. Ensuring effective communication and transparency about AI's role in their treatment can be challenging

evaluations, improves extraction methods, identifies chemical synergies, and provides information on pharmacokinetics, bioavailability, and potential drug-plant interactions. Research on phytochemicals supports the use of herbal remedies in healthcare and supports evidence-based medicine. AI has a variety of benefits over conventional medical procedures. The benefits includes diagnostic precision, personalized treatment suggestions, predictive analytics, supporting medical research, ongoing patient monitoring, increasing access to healthcare in underserved areas, developments in herbal medicine, facilitation of telemedicine, streamlining of administrative tasks, reduction of errors, patient empowerment, and encouraging continuous learning and adaptation. AI has opened up new doors for creativity and precision in conventional medicine, but it does not replace them. However, the integration of AI with conventional medicine faces significant obstacles and moral quandaries. Data security and privacy issues, ethical dilemmas, and regulatory compliance are all crucial factors. While guaranteeing the highest data integrity standards and legal adherence in integrating AI with conventional treatments, it is imperative to uphold the holistic and patient-centered ethos of traditional medicine. To successfully integrate AI into traditional medicine, additional challenges must be overcome, including those related to adoption resistance, overreliance on AI, infrastructure and cost concerns, training and education requirements, liability and malpractice worries, patient trust, and effective communication. Therefore, there is significant promise for improving healthcare while simultaneously maintaining cultural legacy and expertise, thanks to the synergy between AI and traditional medicine. To fully take advantage of these advantages, it is essential to overcome the related difficulties and moral issues. Finding a careful balance between tradition and technology, traditional medicine may survive and develop in the contemporary world while still providing the best possible patient care. This is a remarkable and groundbreaking method of providing healthcare in the twenty-first century: the seamless integration of conventional medicine and AI.

Abstract

The use of herbal medicine for antimicrobial treatment has a rich history that spans cultures and civilizations worldwide. This chapter focuses on the various aspects of herbal medicine, including its extensive classification, antimicrobial properties, factors influencing its efficacy, benefits, challenges, and future prospects. The antimicrobial properties of herbal medicine are remarkable, stemming from phytochemicals like alkaloids, flavonoids, terpenes, and polyphenols. These compounds interfere with microorganisms, creating broad-spectrum activity. Additionally, the synergistic effects of combining medicinal plants enhance their efficacy, thereby potentially reducing the development of resistance. However, herbal medicine's effectiveness is influenced by many factors, including plant species, plant parts used, geographical origin, and mode of administration. Quality control, scientific validation, and standardization are essential to overcome the challenges associated with herbal remedies. Furthermore, the cultural integration and sustainable practices surrounding herbal medicine are vital for its continued success. The prospects of herbal medicine in antimicrobial treatment look promising. Herbal medicine offers alternatives to combat antibiotic resistance, developing new drugs, personalized treatments, and sustainable healthcare practices. Synergistic approaches and global collaboration are expected to expand herbal medicine's role in modern healthcare. Therefore, herbal medicine remains a valuable and versatile tool for antimicrobial treatment. As we navigate the challenges and harness the potential of herbal remedies, they can continue to play a significant role in the treatment of microbial infections, paying homage to the wisdom of our ancestors while addressing the healthcare challenges of our time.

Keywords

Microorganisms · Mode of action · Medicinal plants · Herbal medicine · Human health · Traditional medicine

1 Introduction

A wide range of microorganisms, including bacteria, fungi, and viruses, can cause diseases [36, 39, 51]. Infections caused by bacteria, which are single-celled germs, are quite prevalent. These infections have the potential to cause many different human diseases. Accurate diagnosis and treatment are crucial for the efficient management and cure of bacterial infections, which can vary greatly in severity. Tuberculosis is a typical example of an infectious disease caused by the bacteria *Mycobacterium tuberculosis* with high severity. Infected people can transmit it to others through coughing or sneezing. *Streptococci* species are another type of bacterium that can cause a wide range of illnesses, including the common cold, ear infections, and pneumonia. Infections from Streptococci species can range from mild to severe. *Salmonella* species is another leading bacteria that could cause diseases in humans. *Salmonella* has been widely isolated in food [37] and are characterized by symptoms such as nausea, vomiting, and diarrhea. *Borrelia burgdorferi*, which causes Lyme disease, spreads through the bite of an infected tick and is another bacterium that causes diseases. Lyme disease is characterized by symptoms such as a rash and discomfort in the joints. Cholera, caused by the bacterium *Vibrio cholerae*, is characterized by severe diarrhea. One common route of exposure is through the ingestion of contaminated food, water, or drink. Bacterial meningitis can be caused by various bacteria, including *Neisseria meningitidis* and *Streptococcus pneumoniae*, but there are many other possible culprits as well. Syphilis, caused by the bacterium *Treponema pallidum*, is a chronic infection that worsens with time and can lead to organ failure if not treated. Anthrax, which is caused by the bacterium *Bacillus anthracis*, can show up in a few distinct ways: cutaneously, pulmonarily, or gastrointestinally.

Infections caused by the many species of fungi can show up anywhere in the body in a wide variety of forms [26]. The severity of a fungal infection varies from case to case. Antifungal agents are commonly used as standard treatment, although the specific medication used to treat an infection depends on the kind of fungus involved and its location. For efficient management of fungal infections, a precise diagnosis and a clearly defined treatment plan are essential. For instance, infections of the skin (cutaneous candidiasis), genitalia (vaginal yeast infections), and mouth (oral thrush) are all caused by the same fungus, *Candida*. The type of treatments required for the causative agent for each of these sites differs. Dermatophytes, a group of fungi that causes ringworm, can result in round, itchy rashes when it affects the skin (*Tinea corporis*), scalp (*Tinea capitis*), nails (*Tinea unguium*), and other body regions. Thus, the type of treatment plans also differs. Infections caused by *Aspergillus* fungus are common in immunocompromised people and tend to manifest in the respiratory system. Its extreme form is known as invasive aspergillosis. According to Vuong et al. [62], aspergillosis encompasses a range of infections caused by fungi within the *Aspergillus* genus. Prominent species contributing to these infections include *Aspergillus niger*, *Aspergillus fumigatus*, *Aspergillus terreus*, and *Aspergillus flavus*. The authors further stated that clinical manifestations of aspergillosis are often linked to the state of the immune system, with invasive forms primarily affecting individuals with compromised immune function. Notable examples of invasive diseases include rhinosinusitis and pulmonary aspergillosis. On the other hand, patients with preexisting lung conditions are more prone to developing slower-developing forms of aspergillosis, such as chronic pulmonary aspergillosis, aspergilloma, and allergic bronchopulmonary aspergillosis [62].

The fungus *Histoplasma capsulatum* is responsible for this infection, which spreads through the inhalation of spores found in bird or bat poop. Pneumocystis Pneumonia, caused by the fungus *Pneumocystis jirovecii*, is a serious lung infection that usually affects people with compromised immune systems, such as those with human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS). Meningitis can be caused by the fungus *Cryptococcus neoformans* or *Cryptococcus gattii*, and it primarily affects people with weakened immune systems. According to Marco et al. [48], cryptococcosis, an opportunistic infection, leads to over 100,000 human immunodeficiency virus (HIV)-related deaths annually. The authors further reported that HIV is a common cause of this infection, it can also affect individuals with various other medical conditions such as persons undergoing immunosuppressive therapy, experiencing organ failure syndrome, recipients of organ transplants, individuals with inherent immunological disorders, common variable immunodeficiency syndrome, or hematological diseases.

Infections caused by viruses are common and can have far-reaching effects on the human body [36, 39]. The intensity, mode of transmission, and symptoms of these viral diseases are all different. Viral infections can be prevented and treated with vaccination, antiviral medication, and supportive care. The influenza virus is an infectious respiratory illness that causes fever, coughing, sore throats, and muscle aches. Acquired immunodeficiency syndromes (AIDS) is a disease that can develop if HIV is allowed to continue weakening the immune system. It can have far-reaching effects on one's health. Numerous viruses, including rhinoviruses, can be the cause of the common cold symptoms, which include a cough, a slight fever, a runny or stuffy nose, and mucus production. The new coronavirus severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is what caused the 2019 global pandemic, COVID-19, which primarily affects the respiratory system [55]. The severity of the respiratory distress or pneumonia-like symptoms varies. Hepatitis A, B, C, etc. are all capable of causing liver inflammation, with symptoms ranging from those of the common flu to permanent liver damage. Herpes simplex virus (HSV) can cause painful blisters or sores on the lips or vaginal area, and it can also cause genital herpes [60]. The varicella-zoster virus, which causes chickenpox, is an infectious disease that most frequently affects children and results with an itchy rash and fever. The measles virus causes a high body temperature, a characteristic red rash, and potentially fatal consequences such as pneumonia and encephalitis [52]. The rubella virus causes a minor rash and fever, but its potential to cause birth defects is serious, especially in pregnant women [7]. High fever, bleeding, and organ failure are hallmarks of the Ebola virus disease, which almost usually results in death. Zika virus infection is worrying because of its link to birth abnormalities, even though it may only cause minor symptoms in adults [63]. Rabies is a fatal virus that is spread through animal bites and can have devastating effects on the central nervous system if treatment is delayed [21]. Variola virus (which caused smallpox) has been eradicated thanks to the widespread immunization campaigns, the sickness it produced was extremely dangerous and even lethal [64]. The human body is home to numerous helpful bacteria, and it is important to remember that not all microbes are hazardous.

When bacteria and other microbes develop the ability to resist the drugs intended to combat them, a worldwide health crisis is created [11, 12, 25, 44]. There are far-reaching ramifications to this issue, as well as several serious difficulties. Antibiotic usage in healthcare and agriculture, better diagnostics, increased public knowledge, and research into new antibiotics and alternative treatments are all necessary to combat antibiotic resistance. Actions including reducing inappropriate antibiotic use, increasing vaccination, and creating responsible antibiotic stewardship are necessary to address this critical global health concern. Due to the problem of antimicrobial resistance, plants have emerged as the most promising sources for novel antimicrobials [22, 45–47] and anti-pesticidal agents [23, 27, 33–35, 57, 58, 65]. Throughout human history, countless plants have been harvested from the wild and used for their medical value [6, 33–35]. Phytotherapy, or herbal medicine, has long been an integral part of conventional medical practices across cultural contexts [1, 2, 38]. Herbal medicine is unique because of the strong antibacterial qualities it contains [41]. Herbal remedies have been used for centuries to combat infections caused by bacteria, fungi, viruses, and other microorganisms. This chapter explores the antimicrobial activities of herbal medicine, shedding light on their challenges, opportunities, and future prospects.

2 The Looming Threat of Antimicrobial Resistance: A Global Health Crisis and Multifaceted Challenge

Antimicrobial resistance, commonly called AMR, presents a mounting challenge that jeopardizes our ability to combat bacterial, fungal, and viral infections effectively. This predicament has evolved into a global health crisis, stemming from the capacity of microorganisms such as bacteria, fungi, and viruses to develop resistance to drugs designed to eradicate them. Table 1 summarizes vital information about antibiotic resistance.

2.1 The Complex Nature of Antimicrobial Resistance

AMR encompasses a broad spectrum, encompassing resistance to antibiotics, antifungals, and antiviral medications, with antibiotics being most closely associated with this issue. Resistance can emerge through various mechanisms, including

Table 1 Overview of antibiotic resistance

Aspect	Note about AMR
Complex nature of AMR	AMR includes resistance to antibiotics, antifungals, and antiviral drugs, with antibiotics being most closely associated. Resistance can develop through genetic mutations, gene transfer, and misuse of drugs, leading to a reduction in the efficiency in the use for the treatment of diseases
Public health implications	AMR could lead to prolonged, severe infections, and increased healthcare costs
Global impact of AMR	AMR affects both developed and developing nations, crossing international borders. The economic burden includes rising healthcare costs, reduced productivity, and expenses for developing new antimicrobials for effective use in the treatment of diseases caused by microbial agents
Possible contributing factors to AMR	Inadequate infection control, poor sanitation, and antibiotic use in animal agriculture are contributing to AMR
Strategies for addressing AMR	Combatting AMR requires research into new antibiotics and alternative treatments, educating the local patent dealer and the society as a whole on how this products are utilized
International initiatives	Global organizations and national action plans, such as WHO and the global action plan on AMR, focus on surveillance, responsible use, and research into alternative treatments to address AMR and bringing awareness of the importance and aftermath of this product through media aid
The role of research	Research is essential to understand AMR better and develop innovative solutions. Advancements in diagnostics, therapies, and vaccines are crucial to addressing to challenges posed by antimicrobial resistance
A global effort to address AMR	Addressing AMR requires a global effort involving medical experts, researchers, policymakers, and the public. Public awareness, responsible antibiotic use, and international collaboration are essential to ensure the continued effectiveness of antimicrobial drugs in treating diseases

genetic mutations, horizontal gene transfer, and the inappropriate or excessive utilization of antimicrobial drugs. Infections become increasingly challenging to treat when they involve resilient microorganisms capable of withstanding one or more drugs.

2.2 Implications for Public Health

AMR leads to protracted and severe infections, amplified mortality rates, and escalated healthcare costs. This could be due to diminished availability of effective antibiotics compounds, and the difficulty in treating common diseases caused by microbial agents. Surgical procedures, cancer treatments, and organ transplants become fraught with more significant risks due to the indispensability of antibiotics in averting postoperative infections.

2.3 Global Impact

AMR transcends national boundaries, affecting both developed and developing nations. Its transnational nature enables resistant microorganisms to traverse international borders and disseminate globally. This issue confers a substantial economic burden through elevated healthcare costs, reduced labor productivity, and the outlays associated with developing novel treatments. According to Prestinaci et al. [53], AMR is a grave global public health concern, particularly concerning antibacterial resistance. The authors also reported that the first WHO Global report on AMR, published in 2014, emphasized the extensive impact of antibacterial resistance, its economic and health consequences, and risk factors, and highlighted antibiotic-resistant pathogens, including *Staphylococcus aureus*, *Klebsiella pneumoniae*, non-typhoidal *Salmonella*, and *Mycobacterium* tuberculosis.

2.4 Contributing Factors to Antimicrobial Resistance

The burgeoning issue of antibiotic resistance is aggravated by the appropriate use of antibiotics in clinical settings and their unwarranted agricultural deployment, especially in poultry science and animal husbandry. Substandard infection prevention and control measures in healthcare settings especially in developing countries facilitate the dispersion of resistant microorganisms. Furthermore, inadequate sanitation and hygiene in communities augment the proliferation of antibiotic-resistant microbes, particularly bacteria.

2.5 Strategies for Addressing Antimicrobial Resistance

Effectively combating antibiotic resistance mandates the research and development of novel antibiotics and alternative treatment modalities. AMR can be partly mitigated through judicious antibiotic administration, advancing precise diagnostic techniques, and establishing robust surveillance systems. Vaccination initiatives, aimed at diminishing the impact of infectious diseases, indirectly curtail the demand for antibiotics. Encouraging prudent antibiotic stewardship practices in healthcare settings diminishes superfluous antibiotic use. According to Uchil et al. [59], the strategies to combat this problem involve rational drug use, regulation of over-the-counter availability, enhanced hygiene, infection control, and the development of innovative drugs and vaccines, necessitating a multidisciplinary, collaborative, and regulatory approach.

2.6 International Initiatives

To combat AMR, global organizations and initiatives, such as the WHO and other agencies saddled action plans on AMR, need to encourage research and development in the field. Furthermore, setting up action plans at the national and even state levels focusing mainly on surveillance, responsible antibiotic use, and exploring alternative treatments to combat this issue could yield the desired result.

2.7 The Significance of Research in the Field

Research is imperative for a deeper comprehension of AMR and the formulation of innovative strategies to combat it. Breakthroughs in diagnostics, therapeutic interventions, and vaccines are pivotal in tackling the AMR problem. According to Masterton [49], surveillance studies play a crucial role in detecting emerging pathogens, identifying trends in pathogen incidence, and understanding antibiotic resistance, contributing significantly to the fight against AMR. The author further stated that monitoring pathogen susceptibility and antimicrobial use aids in developing effective strategies to combat AMR and informs clinical decision-making.

2.8 The Menace of Antibiotic Resistance: Impact and Implications on Global Health

Antibiotic resistance threatens the historical value of these medical marvels, with multidrug resistance emerging due to overuse and limited development of new antibiotics [3]. Antibiotic resistance poses a multifaceted threat to our ability to combat bacterial infections, with far-reaching implications. Comprehensive efforts, spanning healthcare, agriculture, and the environment, are needed to combat resistance, and promising alternatives like probiotics, antibodies, and vaccinations offer potential preventive and supplementary treatments in this fight [3]. Table 2 summarizes the menace of antibiotic resistance. In light of these consequences, it is essential to prioritize efforts to combat antibiotic resistance, a critical issue that imperils global health and warrants a concerted, worldwide response.

Therefore, AMR is a complex and pressing challenge requiring a unified global endeavor. The involvement of medical experts, researchers, policymakers, and the general populace is essential to ensure the continued effectiveness of antibiotics and other antimicrobial agents for treating infectious agents.

3 Herbal Medicine: An Overview of Practices and Philosophies

Herbal medicine, or phytotherapy or botanical medicine uses plants and plant-derived compounds for their therapeutic properties. It encompasses a wide range of herbal remedies and approaches to healthcare [4, 5, 20, 40, 42]. Table 3 summarizes the diverse world of herbal medicine classification. Furthermore, herbal medicine is a diverse field encompassing various traditions, plants, preparations,

Table 2 Menace of antibiotic resistance

Consequence	Description
Reduced treatment options	Antibiotic resistance diminishes the efficacy of medications, reducing the available treatments for bacterial infections and potentially turning curable diseases into life-threatening ones
Increased mortality	Antibiotic-resistant microbes particularly bacteria could lead to higher mortality rates in common diseases due to delayed or ineffective treatments, posing risks of severe disease conditions and fatalities
Prolonged illness	Treating antibiotic-resistant infections often demands more intensive interventions, resulting in extended diseases, higher medical costs, and longer hospital stays
Cross-resistance	Bacteria can develop resistance to single drugs and entire classes of antibiotics, thereby intensifying the shortage of effective treatment options
Financial strain	Antibiotic resistance places a significant financial burden on healthcare systems, contributing to increased costs due to extended treatments and possibly prolonged hospitalizations
Public health hazards	Uncontrolled transmission of antibiotic-resistant microbes particularly bacteria in communities and healthcare settings could pose a severe public health risk with rapid dissemination and challenging containment
Impact on surgical procedures and cancer treatment	Antibiotics are crucial for various surgical and cancer treatments, and antibiotic resistance could pose risks to these critical medical interventions
Agricultural use	The use of antibiotics in agriculture to promote livestock growth and disease prevention fosters the development of antibiotic-resistant microorganisms, particularly bacteria, thereby jeopardizing food safety and human health
Global transmission	Antibiotic-resistant microbes particularly bacteria disregard national borders and can spread worldwide, necessitating international collaboration to address the challenge

and philosophies. This section also offers a holistic and natural approach to health and wellness, often complementing conventional medical practices. The choice of herbal remedies and approaches depends on individual health needs, cultural contexts, and personal preferences [13–19, 43].

4 Antimicrobial Properties of Herbal Medicine

Herbal medicine, an ancient practice, has been employed for centuries to address various health conditions. Many herbs possess antimicrobial properties, making them valuable allies against bacterial [28–30], fungal, and viral infections [41]. While herbal medicine can serve as an alternative or complement to conventional antibiotics and antifungal drugs, it's essential to understand its applications in combating infections. This section discusses the various aspects of antimicrobial activities of herbal medicine.

Table 3 Exploring the diverse world of herbal medicine

Herbal medicine categories	Description
Traditional herbal medicine	Ayurvedic medicine (originated from India): Utilizing medicinal plants to enhance overall human health Traditional Chinese medicine: Combining herbal remedies with acupuncture, cupping, and therapies to enhance good health
Western herbalism	Native American herbalism: Indigenous Americans use native medicinal plants for therapeutic purposes Herbalism in Europe: Draws from herbal practices rooted in Greece, Rome, etc. Physiomedicalism: This blends traditional herbal therapy with early modern European medical practices
Modern herbal treatment	Modern Western herbalism: A holistic approach of integrating traditional knowledge and modern research Clinical herbalism: Collaborative patient-specific treatment plans using medicinal plants. Though not encouraged in clinical practice Homeopathy: The use of highly diluted plant substances to enhance natural healing Phytopharmacology: Scientific study of plant compounds or phytochemicals for the development of therapeutic agents
Herbal remedies by plant part	Leaves and flowers, roots and rhizomes, stem bark, seed, and nuts, etc. have shown that they can be used to inhibit the growth of microorganisms
Herbal preparations	Tinctures: Medicinal plant extracts preserved with alcohol Teas: Brewed from dried medicinal plants Infusions and decoctions: Herbal teas are prepared through infusion in boiling water Powders: A ground medicinal plant used in capsules or topically Salves and ointments: Topical herbal applications mixed with bases like beeswax Essential oils: Concentrated plant extracts for topical use and aromatherapy
Effects and qualities of herbal products	Antioxidants: Plants high in antioxidants, e.g., green tea, offer protection against oxidative stress Anti-inflammatory: Turmeric, ginger, etc. possess anti-inflammatory properties Antimicrobial: Herbs like garlic, paw paw, cashew, and lime have antimicrobial properties
Methods for herbal medicine practice	Herbal detoxification: Medicinal plant supporting natural detox processes Herbal tonics: Used for long-term health and vitality Herbal first aid: Herbs like aloe Vera, rosemary etc. for minor injuries and wounds
Herbal medicine systems and philosophies	Holistic herbalism: Focuses on addressing underlying causes of diseases Bioregional herbalism: Emphasizes local medicinal plant use Eclectic herbalism: Draws from diverse herbal traditions and systems

4.1 Types of Antimicrobial Herbal Medicine and Medicinal Plants

A diverse array of antimicrobial herbal medicines and medicinal plants offers unique natural remedies for addressing microbial infections [10, 24, 31, 32]. This section shows some prominent categories of antimicrobial herbal medicine and their associated medicinal plants:

4.1.1 Antimicrobial Medicinal Plants

The microbes under consideration here are viruses, bacteria, fungi, and parasites. Authors have variously reported that plant possess antimicrobial activities including *Anacardium occidentale* [28], *Carica papaya L* [29], *Vernonia amygdalina L.*, and *Ocimum gratissimum L* [30], *Myristica fragrans* [31], *Buchholzia coriacea* [32], *Tetrapleura tetraptera* [10], *Cymbopogon citratus*, *Zingiber officinale* [24], *Medicago sativa, Pimenta dioica, Aloe barbadensis, Aloe vera, Malus sylvestris, Withania somniferum, Euphorbia tirucalli, Momordica charantia, Berberis vulgaris, Ocimum basilicum, Laurus nobilis, Piper betel, Piper nigrum, Vaccinium spp., Arctium lappa, Carum carvi, Rhamnus purshiana, Anacardium pulsatilla, Matricaria chamomilla, Larrea tridentate, Capsicum annuum, Syzygium aromaticum, Erythroxylum coca, Coriandrum sativum, Vaccinium spp., Anethum graveolens, Echinaceae angustifolia, Eucalyptus globulus, Vicia faba, Garcinia hanburyi, Allium sativum, Panax notoginseng, Hydrastis canadensis, Citrus paradise, Camellia sinensis, Peganum harmala, Cannabis sativa, Lawsonia inermis, Humulus lupulus, Armoracia rusticana, Hyssopus officinalis, Rabdosia trichocarpa, Lantana camara, Lawsonia, Santolina chamaecyparissus, Millettia thonningii, Melissa officinalis, Aloysia triphylla, Calendula officinalis, Glycyrrhiza glabra, Thevetia peruviana, Myristica fragrans, Prosopis juliflora, Arnica Montana,* and *Quercus rubra*, among others [8].

Furthermore, Cowan [8] in a review study reported that *Aegle marmelos*, *Taraxacum officinale*, *Coriandrum sativum*, *Panax notoginseng*, *Armoracia rusticana*, *Lantana camara*, *Humulus lupulus*, *Santolina chamaecyparissus*, *Myristica fragrans*, *Prosopis juliflora*, *Arnica Montana*, *Laurus nobilis*, *Piper nigrum*, *Arctium lappa*, *Carum carvi*, *Rhamnus purshiana*, *Citrus paradisi*, *Camellia sinensis*, and *Peganum harmala* among others possess antifungi properties. Cowan [8] in a review study reported that *Arctium lappa, Carum carvi, Rhamnus purshiana, Matricaria chamomilla*, *Eucalyptus globulus*, *Cannabis sativa*, *Hyssopus officinalis*, and *Melissa officinalis* possess antiviral properties. Also, Cowan [8] in a review study reported that *Matricaria chamomilla*, *Hydrastis canadensis*, *Camellia sinensis*, *Lantana camara*, *Millettia thonningii*, *Aloysia triphylla*, *Thevetia peruviana*, *Myristica fragrans*, *Prosopis juliflora*, and *Arnica Montana* among others possess antiparasitic properties. Studies have attributed the antimicrobial potential of these plants to their phytochemical constituents [33–35].

4.1.2 Broad-Spectrum Antimicrobial Agents

Some medicinal plants have demonstrated potentials toward broad-spectrum antimicrobial agents. This is because of the ability to inhibit both gram-positive and negative microbes. Some of these plants include *Anacardium occidentale* [28], *Carica papaya* L [29], *Vernonia amygdalina L.* and *Ocimum gratissimum L* [30], *Myristica fragrans* [31], *Buchholzia coriacea* [32], *Tetrapleura tetraptera* [10], *Cymbopogon citratus*, and *Zingiber officinale* [24]. These antimicrobial medicinal plants exemplify the vast spectrum of natural treatments effective against microbes. When using medicinal plant extracts or parts for therapeutic purposes, seeking guidance on the correct dosage and approach from a healthcare professional or herbalist through consultation is crucial.

4.2 Mechanisms of Action

Antimicrobial agents, antifungals, and antiviral medications deploy various mechanisms to combat microbial infections effectively. These mechanisms are indispensable for identifying and eradicating harmful microbes, particularly bacteria. The diverse mechanisms of action are employed by antimicrobials, especially bacteria.

4.2.1 Protein Synthesis Inhibition

Antibiotics such as tetracyclines and macrolides focus on bacterial ribosomes responsible for protein synthesis. These antibiotics impede bacterial protein production by interfering with this process, inhibiting growth and replication. Also, antibiotics like macrolides, tetracyclines, aminoglycosides, and oxazolidinones target bacterial ribosomal subunits, inhibiting protein production. Amikacin, for example, permanently binds to 16S rRNA and the RNA-binding S12 protein, altering the ribosome's structure and disrupting mRNA codon reading, thereby obstructing tRNA anticodon engagement [61].

4.2.2 Nucleic Acid Synthesis Inhibition

Antimicrobials, including fluoroquinolones, block bacterial DNA replication and transcription, a process known as nucleic acid synthesis inhibition. This disruption hampers bacterial proliferation, leading to cell death. Also, antibiotics like ciprofloxacin target the enzyme DNA gyrase, essential for bacterial DNA synthesis, replication, repair, and transcription. By blocking topoisomerase IV and type II topoisomerase, these antibiotics prevent cell division [61].

4.2.3 Cell Wall Biosynthesis

Bifunctional enzymes involved in bacterial cell wall construction are targeted by bactericidal antibiotics such as penicillin, cephalosporins, and vancomycin [61]. They inhibit enzyme processes by binding to peptide substrates of the peptidoglycan layer [61]. For instance, vancomycin interferes with gram-positive bacteria's cell wall synthesis by binding to D-Ala-D-Ala moieties and preventing the growth of N-acetylglucosamine/N-acetylmuramic acid peptide strands that make up the cell wall's backbone [61].

4.2.4 Destruction of Bacterial Cell Wall

Many antibiotics, like penicillins and cephalosporins, target bacteria by disrupting cell wall synthesis, a vital process in bacterial growth. The absence of cell walls compromises structural integrity, rendering bacteria vulnerable to damage and eventual cell death. Antibiotics like polymyxins modify the structural makeup of lipopolysaccharides in the bacterial outer membrane. Polymyxin B, for example, attaches to the lipid component of lipopolysaccharides, causing structural changes that lead to osmotic imbalance and bacterial death. It also disrupts the integrity of the cytoplasmic membrane, leading to molecular leakage and inhibiting cellular respiration [61].

4.2.5 Interference with Metabolic Pathways

Certain antimicrobials, like sulfonamides, can mimic essential metabolic substrates of microorganisms. This interference disrupts microbial metabolism, hindering the production of critical metabolites and impeding their growth.

4.2.6 Targeting Specific Enzymes

Antifungal drugs, such as azoles, target specific enzymes essential for fungal cell membrane synthesis [56]. Inhibiting these enzymes disrupts fungal cell membranes.

4.2.7 Inhibition of Viral Replication

Antiviral drugs interfere at various stages of the viral replication cycle. Some hinder viral DNA or RNA synthesis, while others prevent viral entry into host cells [50]. Nucleoside analogs, for instance, induce chain termination during viral replication.

4.2.8 Enhancement of the Immune Response

Many antiviral medications, especially those used for retroviruses like HIV, enhance the immune response [9]. This may involve boosting immune cell activity, such as CD4+ T cells, to control viral replication [9].

4.2.9 Interference with Parasitic Metabolism

Antiparasitic drugs disrupt various metabolic pathways specific to parasites, often targeting unique enzymes. For example, antimalarial drugs inhibit heme-detoxification in *Plasmodium* species [54].

Furthermore, the choice of antimicrobial treatment depends on the specific microbial pathogen, its susceptibility to various drugs, and the infection site. A thorough understanding of these mechanisms of action is crucial for devising effective treatment strategies and preventing microbial resistance.

4.3 Broad-Spectrum Antimicrobial Efficacy

Broad-spectrum antimicrobial efficacy is of paramount importance in microbiology and medicine as it signifies the remarkable ability of specific antimicrobial agents, including antibiotics and medicinal plants, to effectively combat a wide range of infectious agents, such as bacteria, fungi, and viruses. This broad-spectrum capability is invaluable in the management of infectious diseases, providing an efficient means to address various illnesses caused by diverse agents. The essential aspects of broad-spectrum antimicrobial efficacy are outlined in Table 4, making it a cornerstone of medical science for combatting a wide array of pathogens responsible for bacterial, fungal, and viral infections.

4.4 Herbal Medicine Formulations

Herbal medicine formulations encompass a wide range of preparations that utilize medicinal plants for health improvement, treatment of various ailments, and addressing medical issues. These formulations have a long history of use across diverse cultures, with their continued popularity driven by the perception of their natural and holistic qualities. Table 5 summarizes the various herbal medicine formulations and uses [4, 15–17, 19]. Herbal medicine formulations offer diverse

Table 4 Aspects of broad-spectrum antimicrobial efficacy

Specific	Activities
Versatility in pathogen eradication	Broad-spectrum antimicrobial agents effectively combat a wide range of microorganisms, and they could be effective in treating patients with mixed infections
Bacterial infections	Broad-spectrum antibiotics address diverse bacteria, including gram-positive and gram-negative types, targeting pathogens such as *Staphylococcus aureus, Escherichia coli*, and *Streptococcus pneumoniae*. Ciprofloxacin and amoxicillin-clavulanate are notable examples
Fungal infections	Broad-spectrum antifungal agents tackle various fungal species, such as yeasts (e.g., *Candida*) and molds (e.g., *Aspergillus*). Common examples of antifungal agents are fluconazole and voriconazole
Viral infections	Broad-spectrum antiviral drugs are vital for treating viral infections, especially when dealing with novel or poorly understood viruses
Complex infections	Complex infections, involving various pathogens (bacteria, fungi, and viruses), benefit from broad-spectrum antimicrobials that address multiple causal agents concurrently
Risks of broad-spectrum usage	Misuse or overuse of broad-spectrum antimicrobials can lead to issues, including antimicrobial resistance, disruption of the body's normal microbiota, and other potential adverse effects
Combination therapy	Combining complementary broad-spectrum antimicrobials can enhance treatment efficacy in complex infections or resistance concerns
Diagnostic dilemmas	The early use of broad-spectrum antimicrobials can pose diagnostic challenges, hindering the identification of the specific pathogen and complicating the selection of targeted therapies
Future of antimicrobial therapy	Broad-spectrum antimicrobials remain crucial in the ongoing battle against infectious diseases, adapting to evolving pathogens and new threats

Table 5 Herbal medicine formulations and their common uses

Formulation	Description	Common uses
Tinctures	Concentrated liquid herbal extracts are preserved with alcohol	Precise dosing, extended shelf life
Teas (infusions/ decoctions)	Herbal teas are produced by steeping dried/fresh medicinal plants in hot water, either as infusions or decoctions	Gentle and calming effects, easy to prepare
Powders	Fine powders are made by grinding dried medicinal plant material, suitable for direct ingestion or mixing into foods	Convenient and versatile for various uses
Ointments and salves	Topical remedies are made by combining medicinal plants in oils (e.g., olive, palm kernel oil, or coconut) with beeswax	Treating skin conditions, cuts, burns, etc.
Capsules	Encased dried or powdered medicinal plant in gelatin or vegetarian capsules, convenient for controlled dosages	Tasteless and easy herbal consumption
Essential oils	Highly concentrated plant extracts capture aromatic and therapeutic qualities for topical or inhalation	Aromatherapy, various therapeutic applications
Syrups	Herbal infusions combined with sweeteners such as honey for flavor enhancement	Palatable herbal remedies, soothing for coughs
Poultices	Herbal pastes are produced by mashing fresh or dried medicinal plants for topical application to localized concerns	Treating muscle discomfort, insect stings, etc.
Compresses	Cloths soaked in herbal infusions or decoctions are applied to affected areas for pain relief or skin issues	Reducing inflammation and alleviating pain
Herbal baths	Herbal additions to bathwater for skin absorption of herbal benefits are believed to aid various conditions	Relaxation, muscle relief, and stress reduction

options, allowing individuals to choose the most suitable approach to address their health needs. However, it’s crucial to exercise caution, particularly when combining herbal medicines with conventional medications or during pregnancy. Consulting a qualified herbalist or healthcare practitioner is advisable to ensure the safe and effective use of herbal medicine formulations [13, 15].

4.5 The Synergistic Antimicrobial Effects of Herbal Medicine and Medicinal Plants

The synergistic antimicrobial effects of herbal medicine and medicinal plants offer a promising approach to treating various infectious diseases [11, 12]. Combining medicinal plants with complementary mechanisms of action, broad-spectrum activity, and increased efficacy can achieve a holistic treatment approach, reducing the risk of resistance development. Table 6 summarizes the synergistic antimicrobial effects of herbal medicine and medicinal plants.

Table 6 Synergistic antimicrobial effects of herbal medicine and medicinal plants

Point	Summary
Enhanced efficacy	Combining medicinal plants enhances antimicrobial effectiveness through synergistic effects
Broad-spectrum action	Certain medicinal plant combinations combat various infectious agents simultaneously, offering a holistic approach
Preventing antibiotic resistance	Herbal synergies can hinder pathogen resistance compared to single antimicrobial agents
Complementary mechanisms	Combining medicinal plants provides multiple modes of action, making it harder for pathogens to develop resistance
Improved tolerance	Herbal mixtures reduce adverse effects associated with high doses of a single medicinal plant, thereby enhancing patient tolerance
Enhanced bioavailability	Some medicinal plants boost the body's ability to absorb antimicrobial compounds effectively when used together
Personalized therapies	Herbal practitioners tailor treatments to individual health needs using synergistic medicinal plant combinations
Traditional wisdom	Traditional medicine systems like Ayurveda and TCM offer valuable knowledge for modern herbal therapy
Use with caution	Careful medicinal plant selection, proper dosages, and guidance from experienced herbalists are crucial for safe treatment
Validation and research	More research is required to bridge traditional and evidence-based medicine to assess herbal combinations' effectiveness

4.6 Safety and Side Effects

Herbal remedies are generally safe at low concentrations for plants that are not toxic to humans. However, caution is advised, this is because some individuals may exhibit sensitivity or allergies to certain medicinal plants. Pregnant or breastfeeding women require special attention when using herbal remedies.

4.7 Precautions

During the use of herbal remedies and medicinal plants, it is crucial to prioritize safety for the patient's well-being and to ensure the treatment's effectiveness. Table 7 summarizes essential safety measures when using herbal medicine and medicinal plants.

4.8 Future Prospects of Herbal Medicine in Antimicrobial Treatment

The future of herbal medicine in antimicrobial treatment is promising and holds the potential to address significant contemporary healthcare challenges. Herbal therapy offers a sustainable, holistic, and potentially more effective approach to combating infectious diseases than synthetic pharmaceuticals. This is particularly relevant as society becomes increasingly aware of the limitations and drawbacks of synthetic drugs. Table 8 summarizes the future prospects of herbal medicine in antimicrobial treatment.

Table 7 Essential safety measures when using herbal medicine and medicinal plants

Safety measure	Summary
Consult a qualified healthcare provider	Seek guidance from a healthcare provider or herbalist before herbal treatment, especially with health issues, pregnancy, or medication use
Adhere to recommended dosages	Follow recommended dosages and preparation methods to avoid adverse effects
Recognize allergies and sensitivities	Be aware of allergies and sensitivities; conduct patch tests when applying herbal remedies to the skin
Quality and source of herbal remedies	Use herbal medicine or medicinal plants from reputable suppliers to ensure quality and authenticity
Educate yourself	It's good to learn about potential side effects, interactions, and contraindications to make informed decisions
Avoid self-diagnosis	It's good to complement rather than replace conventional treatments for serious medical conditions
Start with lower dosages	It is advisable to begin with lower dosages when trying new herbal remedies, monitor effects, and adjust as needed
Maintain records	It is advisable to keep a record of herbal medicine uses including dosages and their effects
Medicinal plant-drug interactions	It is advisable to be mindful of interactions with pharmaceuticals, as medicinal plants may affect medication efficacy or cause reactions
Consider age and health status	It is advisable to tailor herbal therapies based on age and health status; some medicinal plants may not be suitable for certain age groups
Check expiration dates and store properly	It is advisable to verify herbal remedies' expiration dates and store them in a cool, dry place to maintain potency and avoid spoilage
Herbal combinations	Always ensure compatibility and prevent adverse interactions when using combinations of herbs
Seek professional guidance	Always consult with qualified herbalists or healthcare providers for any doubts or concerns about herbal therapy

4.9 Ethical and Sustainable Practices of Herbal Medicine in Antimicrobial Treatment

During the use of herbal medicine and medicinal plants for antimicrobial treatment, ethical and sustainable practices are essential. These practices could ensure responsible and environmentally friendly use of medicinal plants while respecting cultural and ethical considerations. Table 9 summarizes the aspects of ethical and sustainable practices in herbal medicine for antimicrobial treatment.

5 Factors Affecting the Antimicrobial Properties of Herbal Medicine

The effectiveness of herbal medicine in combatting microbial illnesses is influenced by many factors. To successfully apply herbal medicine in healthcare, it is crucial to understand these elements. The primary factors that contribute to the antibacterial

Table 8 Future prospects of herbal medicine in antimicrobial treatment

Prospect	Prospects
Combating antibiotic resistance	Herbal medicine may provide alternative treatments with diverse bioactive compounds, reducing the risk of contributing to antibiotic resistance
Synergistic methods	Research into synergistic medicinal plant combinations can lead to more effective antimicrobial medications by understanding how different herbs interact
Scientific validation and standardization	Extensive scientific research and standardization of herbal medicine could enhance the credibility and reliability of herbal treatments, validating their safety and effectiveness
Identification and isolation of bioactive compounds	The isolation of specific bioactive compounds from medicinal plants can create innovative medications, enhancing the therapeutic effects of herbal therapy
Personalized medicine	The integration of herbal medicine into modern healthcare could allow personalized treatment plans based on an individual's health profile, optimizing herbal antibacterial treatments
Combination therapies	Herbal medicine could complement traditional antimicrobial therapies, thereby potentially reducing synthetic drug dosages, and minimizing adverse effects and resistance development
Green and sustainable healthcare	Herbal medicine aligns with environmentally friendly healthcare as it involves sustainable cultivation and gathering of medicinal plants
Cultural integration	The integration of herbal medicine with modern practices could bridge traditional wisdom and contemporary science, thereby enhancing patient outcomes through collaboration
Educational initiatives	Increasing education and awareness about evidence-based herbal medicine use could empower healthcare providers and the public to make informed choices
Global collaboration	Collaborative efforts between countries and cultures could facilitate the exchange of knowledge about herbal remedies, thereby enhancing the understanding of antimicrobial properties
Regulatory frameworks	The development of effective regulatory frameworks for herbal medicine products could ensure their safety and efficacy while considering their unique characteristics in antimicrobial treatment

effects of herbal medicine are summarized in Table 10. The various factors, from plant characteristics to processing and application methods, influence the antimicrobial properties of herbal medicine. During herbal medicine use in the treatment of microbial infections, it is essential to consider these elements to ensure the proper production and administration of herbal preparations.

Table 9 Aspects of ethical and sustainable practices in herbal medicine for antimicrobial treatment

Practice	Aspects of ethical and sustainable practices in herbal medicine
Ethical sourcing	Medicinal plants should be sourced from ethical suppliers who follow fair trade practices and ensure proper compensation for local communities involved in cultivation and harvesting. Ethical sourcing could promote social justice and community well-being
Biodiversity conservation	Herbal practitioners and growers should prioritize the conservation of plant biodiversity by using sustainable cultivation and harvesting methods, preventing the overexploitation of plant species
Sustainable cultivation and harvesting	Medicinal plants should be grown and harvested using sustainable practices to prevent habitat destruction and depletion of plant populations
Traditional knowledge respect	Ethical herbal medicine should acknowledge and respect the traditional knowledge of indigenous communities and traditional healers. This could be achieved through fair collaboration, consultation with these communities, and respecting their intellectual property rights
Environmental impact consideration	Herbal medicine production should consider the environmental impact of cultivation and processing
Labeling and certification	Herbal medicine products and medicinal plants should be accurately labeled, indicating the botanical name, part of the plant used, and cultivation or harvesting methods
No overharvesting of endangered species	Ethical practices should ensure that endangered or threatened plant species are not overharvested, and alternatives are sought to prevent their extinction
Waste reduction	Sustainable herbal medicine production minimizes waste and utilizes plant parts efficiently to reduce environmental impact
Research on cultivation techniques	Ethical herbal medicine involves research and development to improve cultivation techniques and ensure the long-term availability of medicinal plants
Fair compensation for herbal practitioners	Practitioners of herbal medicine should be made to receive fair compensation for their expertise and efforts, reflecting the value of their knowledge and skills
Traditional healers collaboration	Collaboration between traditional healers and modern healthcare practitioners respects and integrates the wisdom and experience of both to enhance patient outcomes
Education and public awareness	Raising public awareness about evidence-based use of herbal medicine is essential for promoting ethical and sustainable practices. Education could help consumers make informed choices
Regulatory compliance	Compliance with local and international regulations and standards could ensure that herbal medicines meet safety and quality requirements
Scientific validation	All herbal remedies need to undergo scientific validation to assess their effectiveness and safety, thereby bridging the gap between traditional wisdom and evidence-based medicine

Table 10 Factors affecting the antimicrobial properties of herbal medicine

Factor	Effects
Antimicrobial compound levels	Levels of antimicrobial compounds tend to vary among plant species and varieties, affecting their efficacy against specific microbes
Plant part used	The portion of the plant used (leaves, roots, bark, etc.) influences the type and quantity of antimicrobial chemicals present
Geographical origin	Environmental factors like soil, climate, and altitude could impact the chemical makeup of plants, resulting in varying antimicrobial capabilities
Timing of harvest	The plant's developmental stage during harvesting can affect the concentration of active chemicals
Processing and preparation	The processing and preparation methods, such as drying or extraction, can alter the antimicrobial properties of medicinal plants
Storage conditions	Storage conditions, including light, heat, and moisture exposure, can affect herbal products' shelf life and efficacy
Plant maturity	The age of the plant influences the presence and concentration of antimicrobial compounds, thereby impacting on its efficacy
Chemical composition	The specific phytochemicals in medicinal plants, including alkaloids, flavonoids, terpenes, polyphenols etc., determine their antimicrobial qualities
Synergistic effects	Combinations of medicinal plants can create synergistic effects, thereby enhancing antibacterial activity
Dosage and concentration	The appropriate dosage and concentration of herbal remedies affect their efficacy against microbes
Administration method	The manner of administering herbal medication, such as inhalation, topical application, or ingestion, could impact effectiveness of the remedies
Microorganism strain susceptibility	The specific microbial strain and its susceptibility to herbal compounds can influence the effectiveness of herbal therapies
Host factors	Factors related to the host, including age, overall health, and immune function, can affect the efficacy of herbal medicines
Quality control and standardization	Strict quality control methods are required to ensure the consistency and quality of herbal products, thereby influencing their antimicrobial properties
Scientific validation	The extent of scientific research and validation of antimicrobial agents from herbal medicine or medicinal plants can determine its acceptance in modern medicine
Cultural and traditional knowledge	Traditional wisdom and knowledge of herbal use for specific infections play a vital role in herbal medicine's efficacy

6 Benefits of Herbal Medicine in Antimicrobial Treatment

Herbal medicine has maintained its popularity and is increasingly gaining attention in contemporary medical practice due to its numerous benefits in antimicrobial therapy. The benefits of herbal medicine in antimicrobial treatment are summarized in Table 11. While herbal medicine offers numerous benefits in antimicrobial

Table 11 Benefits of herbal medicine in antimicrobial treatment

Benefit	Description
Broad antimicrobial activity	Herbal medicines have a wide spectrum of antimicrobial actions, effectively targeting bacteria, fungi, viruses, and parasites, making them versatile for treating various infectious diseases
Reduced antibiotic resistance	Herbal treatments, rich in diverse phytochemicals, challenge microorganisms in developing resistance, addressing the concern of drug-resistant strains in conventional medicine
Fewer adverse effects	Herbal medicines are generally better tolerated by the body, leading to fewer side effects, suitable for extended use, and ideal for individuals sensitive to prescription drug side effects
Enhanced immune response	Certain medicinal plants such as *Echinacea purpurea*, *Lycium barbarum*, *Ganoderma lucidum*, *Agaricus blazei*, *Clerodendrum splendens*, *Achyranthes bidentata*, *Morinda citrifolia*, *Dimocarpus longan*, *Abrus cantoniensis*, *Rhizoma gastrodiae*, *Momordica charantia*, *Gynostemma pentaphyllum*, *Astragalus membranaceus* etc. possess immunomodulatory properties, strengthening the immune system's ability to combat diseases
Anti-inflammatory effects	Many herbal remedies inherently have natural anti-inflammatory properties, aiding infection management and reducing associated inflammation and discomfort
Synergistic effects	Traditional medical practices, like Ayurveda and TCM, use herbal combinations that create synergistic effects, thereby enhancing infectious disease treatment
Gentle healing approach	Herbal medicine is often considered a gentler approach, working with the body's natural processes, supporting and encouraging them rather than imposing forceful treatments
Cultural and traditional wisdom	Herbal remedies are deeply rooted in cultural and traditional practices, passed down through generations, making them widely accessible
Cultural inclusivity	Herbal medicine is practiced globally and can be culturally inclusive, offering alternative treatment options that respect diverse communities and belief systems

treatment, it's vital to know that it is not a panacea. The effectiveness of herbal remedies varies, and scientific validation is often necessary to confirm their safety and efficacy [4, 13, 16, 17, 19, 43].

7 Challenges of Herbal Medicine in Antimicrobial Treatment

Despite its potential in antimicrobial treatment, herbal medicine has several significant problems that must be carefully addressed before it can be used safely and effectively to treat microbial illnesses. The disadvantages of herbal medicine as an antimicrobial treatment are summarized in Table 12. The use of herbal medicine to treat infectious diseases shows promise, but there are still many obstacles that must be overcome.

Table 12 Challenges in herbal medicine for antimicrobial treatment

Challenge	Description and effects
Lack of standardization	Herbal remedies often lack standardized formulations, making ensuring consistent quality and efficacy difficult. Variations in active substance concentrations can impact treatment outcomes
Quality control	Ensuring the quality of herbal products is challenging due to susceptibility to contamination, adulteration, and mishandling during manufacturing and distribution, compromising safety and effectiveness
Regulatory concerns	Regulatory frameworks for herbal medicine vary between jurisdictions, potentially subjecting herbal products to less rigorous testing and oversight than pharmaceuticals, raising safety and efficacy concerns
Insufficient scientific validation	Although there is growing evidence supporting herbal remedies' antimicrobial properties, rigorous scientific investigations are needed to establish their efficacy and safety conclusively through robust clinical trials
Medicinal plant-drug interactions	Herbal medicines can interact with pharmaceutical drugs, thereby potentially altering the effectiveness of both treatments. Vigilance is necessary to prevent adverse effects and ensure compatibility with conventional therapies
Lack of dosage guidelines	Determining optimal herbal remedy dosages is challenging due to the absence of standardized recommendations. Reliance on traditional knowledge and expert guidance may not always be readily available
Variability in active compounds	Herbal treatment composition varies based on plant species, geographical origin, harvesting conditions, and processing methods, resulting in inconsistent treatment efficacy among patients
Safety concerns	Herbal medicines are generally considered safer than many synthetic drugs; some medicinal plants can induce adverse effects, allergic reactions, or side effects when misused or in high doses, necessitating safety measures
Mislabeling and misrepresentation	The herbal product market faces issues of mislabeling and misrepresentation, with products often fraudulently claimed to treat conditions or inaccurately labeled, leading to consumer confusion and potential harm
Limited access to qualified practitioners	Limited access to qualified herbalists and healthcare providers with herbal medicine expertise in certain regions may result in improper or unsafe herbal remedy use
Resistance to scientific integration	Resistance to integrating herbal medicine into modern healthcare by some traditional practitioners and advocates can hinder collaboration and the development of evidence-based practices
Cultural and ethical considerations	Use of specific herbs for antimicrobial treatment may raise cultural and ethical questions, particularly concerning sustainable sourcing of rare or endangered plant species, necessitating responsible practices

8 Conclusion

There is a wealth of traditional knowledge and growing scientific backing for the antimicrobial remedies found in herbal therapy. Herbal medicines' antibacterial effects show that nature can provide effective treatments for many different kinds of infections. Herbal medicine is unique among other methods of treatment because of the wide variety of herbal traditions, plant sources, and preparation methods. The classification, characteristics, benefits, and potential of herbal medicine in antimicrobial therapy all indicate a promising and fruitful future. The diverse range of approaches, attitudes, and practices that constitute herbal medicine are all reflected in its comprehensive taxonomy. Therapies can range from the ancient knowledge of Ayurveda and TCM to more modern practices like clinical herbalism and phytopharmacology, allowing individuals to choose treatments depending on their cultural background and personal health needs. Bioactive substances found in plants have been hypothesized to explain herbal medicine's antimicrobial effects. Herbal medicine's effectiveness can be affected by many variables, including the type of plant used, how it was prepared, and how it was given to the patient. The overall efficacy of herbal therapy in treating microbial infections can be improved by understanding and optimizing these parameters. Due to benefits of using herbal medicine, the holistic approach to advocate for it is in line with the current movement toward environmentally friendly and sustainable healthcare practices, which seek to meet the requirements of people from all walks of life and all cultures. There are, however, a number of obstacles that need to be overcome before herbal therapy may realize its full potential. Herbal treatments can only be trusted if they have undergone rigorous standardization, quality control, and scientific validation. The abundance of traditional medicinal knowledge should be recognized and incorporated into modern healthcare systems, and regulatory frameworks should be established to oversee herbal goods. Sustainable practices are also essential to defending the ecosystem and keeping the wide variety of medicinal plants available for future generations.
