Exercise caution with some herbs	Avoid herbs like black cohosh, pennyroyal, and blue cohosh, which can induce preterm labor or miscarriage.
Regulation and quality	Quality of herbal products varies; use products from reputable sources to ensure safety and purity.
Dosage and duration	Adhere to recommended dosages and usage durations for safe herbal product use during pregnancy.
Potential benefits	Some herbs may offer advantages for common pregnancy discomforts, but use cautiously and under supervision.
Herbal treatments for common pregnancy symptoms	Examples of herbal treatments for common discomforts.
Individual variability	Response to herbs varies between individuals, emphasizing the need for personalized guidance.
Alternative therapies	In some cases, alternative therapies like acupuncture or aromatherapy can provide relief without potential risks.

3 The Herbal Approach to Pregnancy Care: Tradition, Safety, and Well-Being

The use of herbal plants in traditional medicine has a long-standing history, spanning centuries, and this practice extends to the realm of pregnancy care. Incorporating herbal remedies into pregnancy-related healthcare is a venerable tradition observed across diverse cultures worldwide. These remarkable botanicals, possessing a multitude of therapeutic properties, provide pregnant women with natural solutions to alleviate various discomforts and enhance overall well-being, all while minimizing potential risks associated with pharmaceutical medications. When employed judiciously and under the guidance of knowledgeable practitioners, herbal medicine during pregnancy can serve as a valuable and holistic approach to maintaining a healthy pregnancy and addressing common maternal and fetal health concerns.

Pregnancy is a unique and transformative phase in a woman's life, characterized by physiological, emotional, and hormonal changes. Many expectant mothers contend with a range of common discomforts, including morning sickness, heartburn, insomnia, anxiety, and swollen ankles. Herbal medicine offers a diverse array of herbal remedies that can be harnessed to safely and effectively manage these symptoms [81, 82]. One of the most renowned herbs for alleviating pregnancy-related nausea and vomiting is ginger (Zingiber officinale), with a history of use spanning centuries, and its efficacy in curbing morning sickness is supported by modern scientific research. Ginger can be consumed as tea, capsules, or candied ginger.

Another commonly used herb during pregnancy is chamomile (*Matricaria chamomilla*). Chamomile tea is a soothing and gentle remedy for anxiety, insomnia, and digestive discomfort, rendering it a valuable herb for expectant mothers. The calming effects of chamomile can help reduce stress and promote better sleep, which is especially beneficial during pregnancy when sleep disruptions are expected.

Beyond managing specific discomforts, herbal medicine during pregnancy encompasses herbs recognized for their uterine toning and nourishing properties. For example, raspberry leaf (*Rubus idaeus*) is a well-regarded herb for strengthening uterine muscles and preparing the body for labor when consumed as tea in the second and third trimesters. Nettle (*Urtica dioica*), celebrated for its rich nutritional profile, provides essential vitamins and minerals, including iron and folic acid, crucial for both the developing fetus and the expectant mother's health. Nettle tea is often recommended to combat anemia, improve circulation, and alleviate swelling, which are common concerns during pregnancy.

Herbal medicine also addresses the emotional and psychological aspects of pregnancy. Herbs like St. John's Wort (*Hypericum perforatum*) and lavender (*Lavandula angustifolia*) can offer relief from anxiety and mood swings. St. John's Wort, known for its antidepressant and anti-anxiety properties, can be safely used in moderation. Lavender essential oil, when diluted and applied topically or diffused, can help soothe nerves and promote relaxation.

However, it is essential to underscore the need for caution when considering herbal remedies during pregnancy. Safety is paramount, as certain herbs may be contraindicated during pregnancy due to potential adverse effects. Pregnant women should consult a qualified herbalist, naturopathic doctor, or midwife experienced in herbal medicine to select appropriate herbs and dosages tailored to their unique needs. Additionally, expectant mothers should be aware of herbs to avoid during pregnancy. Herbs such as black cohosh (*Actaea racemosa*), pennyroyal (*Mentha pulegium*), and tansy (*Tanacetum vulgare*) have been associated with adverse pregnancy outcomes and should be strictly avoided. Herbs that stimulate uterine contractions, like blue and black cohosh, should not be used without proper supervision during pregnancy.

Regulation and quality control of herbal products are crucial considerations when incorporating herbal medicine during pregnancy. Pregnant women should obtain herbs from reputable suppliers to ensure their purity, free from contaminants, and that they have been responsibly harvested and processed. Choosing organically grown herbs whenever possible is essential to minimize exposure to pesticides and other potentially harmful chemicals.

It is essential to emphasize that herbal medicine should not replace standard prenatal care, including regular check-ups with healthcare providers, ultrasound scans, and appropriate screenings. Instead, it should complement conventional medical care by addressing specific concerns and promoting overall well-being, providing a holistic approach to pregnancy care.

The importance of informed and cautious herbal medicine use during pregnancy cannot be overstated. Each pregnancy is unique, and what may be safe and beneficial for one expectant mother may not be suitable for another. This underlines the necessity of individualized care and guidance from a qualified herbalist or healthcare practitioner. Such an approach ensures that the chosen herbs are appropriate for the expectant mother's health and pregnancy. Herbal medicine offers a holistic and natural approach to supporting maternal and fetal health during pregnancy. When used with caution and under the guidance of experienced practitioners, herbal remedies can relieve common discomforts, nurture the mother's overall well-being, and even prepare the body for labor and delivery. However, pregnant women need to approach herbal medicine with a discerning eye, seeking professional guidance to ensure the safety and efficacy of their chosen herbs [98]. With the right approach, herbal medicine can be a valuable and harmonious addition to a healthy and happy pregnancy journey. Numerous studies have indicated that pregnant women have a range of options for consuming herbal medicines (HMs) during pregnancy. These options include unprocessed herbal mixtures, herbal extracts, finished and branded herbal medicines, as well as nutritional supplements containing specific HMs, vitamins, and minerals [57]. In Table 3, you can find a list of medicinal plants commonly used during pregnancy and their intended purposes.

Pregnant women across the globe are increasingly turning to herbal remedies as they seek natural solutions to common discomforts associated with pregnancy. Among the most widely embraced herbal options are ginger, chamomile, peppermint, Echinacea, cranberry, Vaccinium, and garlic. These herbal choices transcend geographical boundaries, recognized for their potential to alleviate typical pregnancy-related ailments.

For instance, ginger is highly regarded for its ability to combat morning sickness, while chamomile and peppermint are sought after for their calming properties. Cranberry and Echinacea are known for their respective benefits in promoting urinary health and bolstering the immune system. Garlic is appreciated for its versatile medicinal properties.

Regional preferences for specific herbal remedies may vary. In Eastern and Western Europe, uva ursi has traditionally been employed for its purported urinary tract benefits. Conversely, in Eastern European nations, herbal options like motherwort, centaurium erythraea, and lovage have taken precedence in the repertoire of pregnant women. These regional variations are deeply rooted in historical practices and cultural traditions.

Understanding the popularity and regional disparities in herbal choices among pregnant women is of paramount importance for both healthcare professionals and expectant mothers. It facilitates informed decision-making, underscoring the significance of effectiveness and safety. This global perspective serves as an invaluable resource for promoting the well-being of both mothers and their unborn children as herbal medicine continues to play a role in pregnancy care.

In Sweden, expectant mothers often incorporate dietary supplements such as Floradix® IRON + HERBS, ginseng, and valerian into their routines [35]. The decision to use herbal medicines during pregnancy can yield benefits for both the

Table 3 Different medicinal plants used by pregnant women in their different physiological conditions of pregnancy

Physiological condition	Medicinal plants	Scientific names
Cold and flu	Echinacea	*Echinacea purpurea*
	Elderberry	*Sambucus nigra*
Pain (Gastralgia and other types of pain)	Chamomile	*Matricaria chamomilla*
	Peppermint	*Mentha × piperita*
	Lavender	*Lavandula angustifolia*
Gastrointestinal disorders, constipation, flatulence	Fennel	*Foeniculum vulgare*
	Dandelion	*Taraxacum officinale*
Anxiety, stress	Valerian	*Valeriana officinalis*
	Lemon balm	*Melissa officinalis*
Urinary tract infection	Cranberry	*Vaccinium macrocarpon*
	Uva Ursi	*Arctostaphylos uva-ursi*
Fetal health promotion	Raspberry leaf	*Rubus idaeus*
	Nettle leaf	*Urtica dioica*
Labor preparation, facilitation, and induction	Black cohosh	*Actaea racemosa*
	Blue cohosh	*Caulophyllum thalictroides*
Milk production and secretion	Fenugreek	*Trigonella foenum-graecum*
	Blessed thistle	*Cnicus benedictus*
Nausea and vomiting	Ginger	*Zingiber officinale*
Stress and anxiety	*Matricaria chamomilla* (chamomile)	*Matricaria chamomilla*
Digestive discomfort	Peppermint	Mentha × piperita
Immune support	Echinacea	*Echinacea purpurea*
Uterine tonic for late pregnancy	*Rubus idaeus* (raspberry leaf)	*Rubus idaeus*
Sleep and relaxation	*Lavandula angustifolia* (lavender)	*Lavandula angustifolia*
Nutrient support	*Urtica dioica* (stinging nettle)	*Urtica dioica*
Preparing for labor	*Rubus idaeus* (red raspberry leaf)	*Rubus idaeus*

mother and the unborn child, and they are occasionally employed to manage specific health issues. Some of the most frequently mentioned uses of medicinal plants during pregnancy include addressing concerns like nausea and vomiting, urinary tract infections (UTIs), childbirth preparation and comfort, common colds and flu, digestive issues, pain management, improving fetal outcomes, preventing abortion, managing anxiety, maintaining general health, and alleviating swelling [33, 57].

4 Global Perspectives on Herbal Medicine Use During Pregnancy: Practices, Prevalence, and Safety Considerations

The utilization of HMs is not confined to specific nations; however, certain HM practices are more prevalent in particular regions. For instance, expectant mothers in India and Ghana display a higher tendency to use HMs for the prevention of abortions and to enhance the health of their unborn children, compared to their counterparts in more industrialized regions [5, 15].

These practices are often rooted in a variety of factors, some of which are directly related to the well-being of the fetus. For example, the prevention of newborn hyperbilirubinemia, protection of the unborn child from injury, promotion of increased prenatal weight, and support for optimal brain development are among the commonly cited reasons [23, 105]. Surprisingly, certain indications also strongly influence societal perceptions of pregnant women. In places like Lesotho and Zimbabwe, it is customary for pregnant women to use HMs, and adherence to cultural standards often mandates this practice [72, 94, 95, 103].

The use of regional medicinal plants for prenatal care is widespread in developing nations, especially in Africa and Asia [68, 96, 97, 112]. These medicinal herbs are consumed in various forms, including decoctions, medications, and soups. For example, in South Africa, Zulu women in their final trimester frequently consume a concoction known as "Isihlambezo." This mixture, which comprises several medicinal herbs, is believed to promote a favorable pregnancy and facilitate uncomplicated labor [17]. Some of the most commonly used ingredients in this mixture include *Agapanthus africanus* (L.) Hoffmanns, *Pentanisia prunelloides* (Klotzsch ex Eckl. & Zeyh.), *Clivia miniata* (Lindl.) Verschaff. Walp., and *Gunnera perpensa* L. [17].

The specific formulations employed often depend on several factors, including the preferences of the expectant mother, the traditional healer's recommendations, and the woman's current health status. It's worth noting that the uterine toning effects of these herbal mixtures are activated upon consumption, but excessive doses leading to heightened vaginal stimulation may result in adverse effects. For example, the "Isihlambezo" mixture has been linked to low newborn birth weights, embryonic meconium spotting (a potential sign of prenatal distress and oxygen deprivation), and uterine breach [17].

Malawi, situated in southeastern Africa, is renowned for its picturesque landscapes, diverse cultural heritage, and the long-standing practice of utilizing herbal medicine and medicinal plants. Traditional healers and local communities in Malawi have relied on the healing properties of indigenous plants to address a wide array of health concerns. This practice is deeply ingrained in Malawian culture and operates in tandem with modern medical approaches.

The realm of Malawian herbal medicine encompasses a plethora of plant species, each possessing distinctive therapeutic attributes. Notably, the Moringa tree (*Moringa oleifera*) stands as a symbol of nutrition and offers a potential solution to combat malnutrition, a prevailing challenge in the nation. Additionally, Malawi's abundant flora includes plants like *Artemisia annua*, known for their antimalarial properties, providing a natural alternative in the fight against this prevalent disease. In Malawi, the “Mwanamphepo” mixture is commonly used to induce labor and consists of various herbs, including *Ampelocissus obtusata* (Welw. ex Baker) Planch., *Cyphostemma hildebrandtii*, and *Cissus verticillata*, often consumed with oatmeal just before childbirth (Maliwichi-Nyirenda and Maliwichi 2010).

Medicinal plants are integral to the Malawian healthcare landscape. The country boasts a diverse array of plant species renowned for their medicinal applications. For example, Senna (*Cassia abbreviata*) is employed for its laxative qualities, while the African potato (*Hypoxis hemerocallidea*) is sought after for its potential to address a spectrum of health issues.

This exploration of herbal medicine and medicinal plants in Malawi seeks to shed light on the profound interplay between the nation’s rich biodiversity and its healthcare traditions. We delve into the cultural significance, traditional healing methodologies, and the potential integration of these herbal therapies into the broader healthcare framework. Furthermore, we address the vital issue of sustainability concerning medicinal plants and their role in delivering accessible and cost-effective healthcare solutions to the people of Malawi.

In Korea, the herbal combination “Anjeonicheon-tang,” which includes therapeutic plants like Atractylodes macrocephala Koidzumi white rhizoma, *Glycyrrhiza glabra* L., and Panax ginseng C.A.Mey, is used to address pregnancy-related symptoms, particularly hyperemesis gravidarum. In Taiwan, a tea known as “An-Tai-Yin,” composed of medicinal plants aimed at inducing labor, is commonly consumed by expectant mothers [20]. However, mothers who consumed An-Tai-Yin were found to have an increased risk of connective tissue, joint, and ocular abnormalities in their babies [20].

Research conducted by Pallivalapila et al. [102] suggests that the first and third trimesters witnessed the highest prenatal use of herbal medicines. During the first trimester, herbal remedies were often used to manage early pregnancy symptoms like morning sickness, nausea, and gastrointestinal issues. In contrast, the third trimester use aimed at aiding in childbirth and preparing the cervix for delivery [79, 97]. Nevertheless, it was not uncommon for women to use herbal medicines throughout their entire pregnancy with the goal of promoting both maternal and fetal health. Notably, no consistent trends have been observed by scholars [110], and some women continued using these herbal remedies until they felt better [77].

According to Kennedy et al. [58], married women with higher levels of education were more inclined to use complementary and alternative medicine (CAM) that included herbal medicines during pregnancy (Forster et al. 2006; [2, 57, 58]). This demographic of herbal medicine consumers was typically middle class, Caucasian, non-smoking males over the age of 30 who had prior experience with herbal remedies. On the other hand, in Eastern European countries, pregnant women under the age of 20 were more likely to use herbal medicines [57].

In contrast, in Africa and Asia, women who incorporated herbal medicines during childbirth tended to be under the age of 30, possess lower socioeconomic status, lack a high school diploma, and reside in remote areas with limited access to public healthcare facilities [54, 113]. These pregnant women often sought advice from friends, family, traditional birth attendants, local plant vendors, and herbalists before deciding to use herbal medicines [54, 57, 113].

Media coverage played a role in influencing the decision to use herbal medicines during pregnancy in industrialized nations, as reported by Hall et al. [33]. In Eastern Europe, pregnant women typically followed their doctor's recommendations regarding herbal medicine use [57].

The practice of using both herbal medicines and traditional remedies during pregnancy is common worldwide [36, 79, 110, 111]. It is worth noting that when herbal medicines are used in conjunction with conventional drugs, they can either enhance or diminish the effects or side effects of these medications. However, many pregnant women refrain from disclosing their herbal medicine usage to healthcare providers due to the stigma attached to this practice.

Overall, a significant proportion of pregnant women turn to herbal medicines and traditional remedies for support during pregnancy, labor, and postpartum, with the prevalence of herbal medicine use varying based on demographic factors such as geographical location, cultural background, and educational level. This highlights the urgent need for research into the efficacy and safety of herbal medicines and traditional plant remedies in pregnant individuals, and potentially, in humans. Table 4 summarizes the global Perspectives on Herbal Medicine Use During Pregnancy: Practices, Prevalence, and Safety Considerations.

5 Herbal Medicine in Pregnancy: Nurturing Maternal and Fetal Health

The utilization of herbal plants in traditional medicine has a rich historical tradition that spans centuries and extends its influence to prenatal care. Across diverse cultures globally, the incorporation of herbs into pregnancy-related healthcare has been a time-honored practice. These botanical wonders, with their diverse therapeutic attributes, offer expectant mothers natural remedies to alleviate a variety of discomforts and enhance overall well-being, all while mitigating potential risks associated with pharmaceutical medications.

When used judiciously and under the guidance of knowledgeable practitioners, herbal medicine during pregnancy can be a valuable and holistic approach to fostering a healthy gestation period and addressing common maternal and fetal health concerns. Pregnancy is a remarkable and transformative phase marked by physiological, emotional, and hormonal changes. Many expectant mothers grapple with a range of discomforts, including morning sickness, heartburn, insomnia, anxiety, and swollen ankles. Herbal medicine provides a spectrum of botanical solutions that can effectively manage these symptoms safely.

One of the most renowned herbs for alleviating pregnancy-related nausea and vomiting is ginger (*Zingiber officinale*). With a history of use spanning centuries, modern scientific research substantiates ginger's efficacy in curbing morning

Table 4 Global perspectives on herbal medicine use during pregnancy: practices, prevalence, and safety considerations

Topic	Key findings
Regional variation in HM practices	Herbal medicine (HM) practices during pregnancy vary across regions. In India and Ghana, there's a higher tendency to use HMs for pregnancy health compared to industrialized regions. Cultural factors often influence this choice.
Prevalent reasons for HM use	Reasons for using HMs during pregnancy include preventing newborn hyperbilirubinemia, protecting the unborn child from injury, promoting increased prenatal weight, and supporting optimal brain development.
HM use in developing nations	Developing nations, particularly in Africa and Asia, widely use regional medicinal plants for prenatal care. These medicinal herbs are consumed in various forms, but some formulations may have adverse effects.
Country-specific HM practices	Specific examples include South African Zulu women using "Isihlambezo," Korean "Anjeonicheon-tang" for hyperemesis gravidarum, and Taiwanese "An-Tai-Yin" to induce labor (with reported risks to babies).
Trimester-specific HM use	HM use peaks during the first and third trimesters. In the first trimester, it's used to manage early pregnancy symptoms, while the third trimester use aims to aid in childbirth and prepare the cervix for delivery.
Demographic variations	Demographic factors like education and age influence HM use. Higher education levels correlate with increased CAM usage, while in Eastern Europe, younger women are more likely to use HMs.
Socioeconomic and cultural factors	In Africa and Asia, women with lower socioeconomic status, lacking a high school diploma, and residing in remote areas tend to use HMs. Societal perceptions and cultural practices often influence HM use.
Media influence	Media coverage affects HM use in industrialized nations. In Eastern Europe, pregnant women typically follow their doctor's recommendations regarding herbal medicine use.
HM use alongside conventional medicine	Many pregnant women use both herbal medicines and conventional remedies worldwide. The combined use can enhance or diminish the effects of conventional drugs, but there's a stigma associated with HM use.
Need for further research	The prevalence and safety of herbal medicines and traditional plant remedies during pregnancy call for further research and exploration, taking into account regional, cultural, and demographic differences.

sickness. It can be incorporated into one's diet in various forms, such as ginger tea, capsules, or candied ginger.

Chamomile (*Matricaria chamomilla*) is another herb frequently employed during pregnancy. Chamomile tea is a soothing and gentle remedy for anxiety, insomnia, and digestive discomfort, making it a valuable herbal option for expectant mothers.

Its calming effects can help reduce stress and facilitate improved sleep, which is especially valuable during pregnancy when sleep disruptions are common.

However, it is crucial to exercise caution when considering herbal remedies during pregnancy, with safety being of utmost importance. Some herbs can be contraindicated due to their potential to induce adverse effects. Pregnant women should consult with qualified herbalists, naturopathic doctors, or experienced midwives to ensure the selection of appropriate herbs and determine suitable dosages tailored to their specific needs.

In addition to professional consultation, expectant mothers should familiarize themselves with herbs that must be avoided during pregnancy. Herbs like black cohosh (*Actaea racemosa*), pennyroyal (*Mentha pulegium*), and tansy (*Tanacetum vulgare*) have been associated with adverse pregnancy outcomes and should be categorically avoided. Furthermore, herbs known to stimulate uterine contractions, such as blue and black cohosh, should not be used without appropriate supervision during pregnancy.

The regulation and quality control of herbal products are paramount considerations when incorporating herbal medicine during pregnancy. Pregnant women should source their herbs from reputable suppliers to ensure that these botanicals are free from contaminants and have been harvested and processed responsibly. Opting for organically grown herbs whenever possible is essential to minimize pesticide exposure and potential exposure to other harmful chemicals.

It is essential to reiterate that herbal medicine should not replace standard prenatal care. Regular check-ups with healthcare providers, ultrasound scans, and appropriate screenings are non-negotiable components of comprehensive pregnancy care. Herbal medicine should complement conventional medical practices by addressing specific concerns and enhancing overall well-being.

When approached with prudence, herbal medicine during pregnancy offers a holistic and natural methodology for supporting maternal and fetal health throughout this unique journey. When carefully selected and monitored under the guidance of experienced practitioners, these herbal remedies can effectively alleviate common discomforts, nurture maternal well-being, and prepare the body for labor and delivery. Pregnant women, however, need to approach herbal medicine with a discerning eye, seeking professional guidance to ensure the safety and efficacy of their chosen herbs. With a thoughtful and informed approach, herbal medicine can be an invaluable and harmonious addition to a healthy and joyful pregnancy experience.

6 Raspberry Leaves in Pregnancy: A Natural Supportive Remedy

Various herbal plants play a role in pregnancy support, particularly tonic herbs that are deemed safe for regular consumption during pregnancy. These herbs serve a dual purpose: they are non-toxic and not highly therapeutic, making them suitable for expectant mothers, while also nourishing the mother and fortifying the cervix in preparation for a smooth childbirth. Among the herbs falling into this category, we find raspberry leaves (*Rubus idaeus*), partridge berries (*Mitchella repens*), and stinging nettles (*Urtica dioica*).

Raspberry leaves have a long history of use by pregnant women in China, Europe, and North America. Both fresh and dried raspberry leaves can be steeped in hot water to create a flavorful tea with high nutritional value, believed to promote the well-being of the pregnant woman's cervix. Additionally, women at risk of miscarriage have been encouraged for centuries to incorporate raspberry leaf tea into their daily routines throughout pregnancy, as it is believed to aid in carrying the pregnancy to full term. This recommendation underscores the significance of proper nourishment in reducing the likelihood of pregnancy and childbirth complications, such as miscarriage, postpartum bleeding, and premature or delayed labor [3].

Raspberry leaves are a rich source of essential nutrients, including vitamins A, B complex, C, E, as well as minerals like calcium, iron, phosphate, and potassium [4]. Furthermore, they contain magnesium and iron [10]. The herb's bitterness, invigorating properties, and soothing effects can be attributed to its tannins, polypeptides, and antioxidants. Of particular importance is the alkaloid fragarine, discovered in 1941, which is known to inhibit uterine contractions [12]. Some reports suggest that fragarine strengthens the muscles of the uterus and pelvis, potentially easing the process of childbirth. While animal studies have shown that raspberry leaf can both stimulate and relax the uterus, human research in this regard has been limited. However, a recent observational study involving raspberry leaf tea in women of reproductive age indicated a reduced risk of preterm or delayed labor and a decreased need for medical intervention during labor. Notably, the plant has not been linked to adverse pregnancy outcomes, and there is no evidence to suggest it is toxic or teratogenic. While raspberry leaf tea has been promoted for use throughout pregnancy, its significant impact on the endometrium is sometimes recommended only in the third trimester [25]. Additionally, chewing on small fragments of raspberry leaf tea ice cubes may provide a moist tongue, which, in turn, could facilitate uterine contractions.

7 Herbal Remedies for Pregnancy: Efficacy and Safety

Approximately 25% of pregnancies end prematurely, and the causes can vary, including the mother's immune system rejecting the embryo, having an incompetent cervix, or carrying a nonviable fetus. Miscarriage is a distressing issue, and women at risk of losing their pregnancies often face limited options. Early pregnancy symptoms, like spotting and cramps, typically lead to bed rest until the threat either subsides or results in a miscarriage [119].

However, two North American native plants, black haw (*Viburnum prunifolium*) and false unicorn (*Chamaelirium luteum*), offer potential for miscarriage prevention.

Black Haw: Historically, Eclectic Physicians used both black haw and its close relative, cramp bark (*Viburnum opulus*), for similar purposes, such as preventing and treating abortion, preparing for labor, and alleviating false labor and postpartum symptoms [118]. Black haw has been found effective when used in small, gradual amounts as a preventative measure or in larger doses for imminent situations, according to Eclectic practices [120]. As a result of widespread use in both alternative and conventional medicine, we now have a better understanding of the pharmacological effects of black haw. Its active compounds, salicin and scopoletin, act as efficient uterine antispasmodics, soothing and relaxing uterine muscles. In modern Chinese therapy, black haw is employed to safeguard pregnancies that might otherwise end in abortion due to cervical laxity or uterine instability. It remains unclear whether the herb's efficacy varies depending on its form, whether consumed as a pill, tea, or extract. Although clinical studies are limited, black haw and cramp bark are generally considered safe for use throughout pregnancy [116]. However, due to the potential risk of syncope (fainting), it is advisable for pregnant or nursing women to avoid high doses or regular usage of black haw. There is also anecdotal evidence suggesting that cramp root might be a viable alternative.

False Unicorn: False unicorn, commonly used in herbal preparations to enhance fertility, reduce the risk of abortion, and prepare the body for childbirth, is associated with various benefits. This herb is particularly known for its ability to address uterine incontinence and strengthen a cervix that has loosened due to recurrent pregnancies. It is believed that taking false unicorn before pregnancy may enhance a woman's fecundity [101]. In certain situations, women turn to false unicorn to either prevent miscarriage or alleviate the symptoms of an impending loss, such as bleeding and cramps [65].

While there is limited rigorous scientific testing on the safety of false unicorn during pregnancy, it is generally considered safe by most herbalists. Some women have used false unicorn even after the onset of abortion, taking frequent doses to successfully carry their pregnancies to full term. There is some indication that the plant may lead to increased levels of human chorionic gonadotropin in the blood, potentially averting abortion. Additionally, cases have been reported where false unicorn and other herbs effectively halted excessive bleeding associated with abortion.

Despite the absence of clinical studies regarding the pharmacological effects of false unicorn, it is commonly believed to possess qualities that restore ovarian and uterine health while acting as an emmenagogue. Contrary to popular belief, it does not stimulate the uterus during pregnancy, but it may contribute to hormone regulation and strengthen the liver and intestinal system [19, 78, 80]. False unicorn can be consumed in various forms, including as a drink, extract, or pill. The specific active components in these different forms are not well documented due to limited research on the plant's mechanisms. Given its acrid flavor, false unicorn is typically preferred in pill or extract form rather than being brewed into a beverage.

Labor Induction: In North America, women often turn to various herbs for labor induction, as highlighted by the research of Moshi and Mhame [71]. Some commonly used herbs for this purpose include blue cohosh (*Caulophyllum thalictroides*), black cohosh (*Cimicifuga racemosa*), and even beetroot (*Trillium erectum*).

Blue Cohosh, a plant native to North America, holds a long history of use by Native Americans and Eclectic Physicians for its medicinal properties, particularly the roots and tubers. It was employed to hasten labor in cases where it had stalled due to maternal frailty, exhaustion, or a lack of reproductive energy [56, 94, 95]. During the 1800s, it gained popularity in both Western and African-American traditional medicine as a means of inducing childbirth and increasing menstruation flow. In modern herbal medicine, blue cohosh is highly regarded for its uterus-stimulating, antispasmodic, and emmenagogue properties [39, 91, 100]. This plant owes its oxytocic effects to flavonoids such as caulosaponin and caulophyllosaponin, making it one of the most potent natural labor inducers. It is often blended with other herbs, particularly black cohosh, in a 1:1 ratio to expedite labor. However, it's important to note that some of blue cohosh's active components are not water soluble, making it more effective as a preparation rather than a tea.

Recent concerns regarding the safety of blue cohosh have emerged. There have been reports of increased fetal distress, as evidenced by meconium-stained amniotic fluid or fetal arrhythmia, and elevated fetal heart rates associated with its use. Some case reports highlight severe health issues in newborns whose mothers used blue cohosh, particularly when used alongside black cohosh. One study [49] described a case where a woman took an unknown quantity of blue and black cohosh to induce labor, resulting in the newborn exhibiting symptoms of illness, necessitating hospitalization and medical intervention for convulsions, renal injury, and artificial respiration. This has raised concerns about the safety of blue cohosh.

Blue cohosh contains compounds like caulosaponin, which researchers believe may contribute to these health problems by constricting cardiac blood vessels and inducing harmful myocardial responses. Some experts have argued that our understanding of these plants' dangers is based on studies conducted on individual components in animals, often using unrealistically high doses. The toxic impact of caulosaponin in animal studies was observed at levels far exceeding what a human would typically consume and could be fatal.

Furthermore, there have been documented cases of nausea, severe gastrointestinal discomfort, and other adverse reactions associated with blue cohosh use. Additionally, blue cohosh contains at least ten alkaloids, including the teratogenic-methylcytosine and extremely embryotoxic sparteine. There's also concern regarding anagyrine, a substance found in the plant's roots, which has been linked to congenital disabilities, such as twisted calf syndrome. Although there are no direct evidence of such issues in humans, a case report connected a similar genetic malformation in a human to the consumption of anagyrine-contaminated goat's milk. However, teratogenic effects of anagyrine have not been observed in studies involving rat embryos.

Given the growing body of evidence pointing to potential risks, it's advisable to exercise caution when considering the use of blue cohosh. The continued use as a labor induction method in North America suggests a need for further research and education on its safety [29, 92] (▶ Chap. 59, "Research Needs of Medicinal Plants Used in the Management and Treatment of Some Diseases Caused by Microorganisms"). Conversely, black cohosh, another plant with labor-inducing potential, has a lower reputation outside North America. While no poisonous, carcinogenic, or teratogenic traits have been established, some European authorities recommend against its use during pregnancy and breastfeeding [50, 107]. Extremely high doses of black cohosh may lead to unpleasant side effects, including intense pain, vertigo, nausea, and vomiting. It is more common to use blue cohosh, but midwives often recommend a combination of these plants to expedite labor. Black cohosh is believed to complement the effects of blue cohosh by regulating the frequency and intensity of uterine contractions. Its purported properties include being antispasmodic, calming, vasorelaxant, and hypotensive.

Beetroot, a plant historically used by Native Americans in North America, particularly its rhizomes, has been employed for centuries to aid in childbirth and reduce postpartum hemorrhage. The term “beth” in beetroot likely stems from “birth” [119]. This maroon-flowered plant was commonly used by early American colonies, Shakers, and Eclectic Physicians to treat conditions such as vaginal bleeding and heavy menstrual flow [13]. While scientific investigations into beetroot’s pharmacological effects are lacking, ample evidence suggests its efficacy in inducing uterine contractions. It is known for its properties as an antihemorrhagic and emmenagogue for the genitourinary system, and it also possesses expectorant, astringent, and antimicrobial qualities [87, 89, 90].

In modern herbal medicine, beetroot, often consumed as a drink or extract, is a common choice for stimulating labor that has stalled. Laboratory tests have shown that saponin glycosides present in beetroot and its close relative, *Trillium grandiflorum*, have significant antifungal properties. However, the glycosides in beetroot have not been thoroughly examined regarding their chemistry and toxicity. Clinical studies on beetroot are highly unlikely due to its limited recognition, even though they could provide valuable insights into its phytochemistry and pharmacology. While more research is needed, beetroot may be considered a potentially safer option for inducing labor compared to other alternatives [22].

8 The Efficacy and Safety of Herbal Medicine in Pregnant Women

Historically, people have traditionally relied on the wisdom and experience of their elders to ascertain the safety and effectiveness of specific medicinal plants. Over the past two to three decades, extensive preclinical and clinical research has been conducted to shed light on the efficacy and safety of various therapeutic plants and herbal combinations. Some of these studies have involved in vivo and in vitro assessments to evaluate their potential embryotoxicity.

For instance, ginsenosides, the active components in ginseng, had direct teratogenic effects on rat fetuses, as determined in an in vitro investigation [18]. This study further inferred that these herbal medicines, due to their oxytocic activity, might lead to uterine hyperstimulation, potentially resulting in fetal ischemia and premature birth, based on their findings using an isolated rat uterus model.

In another study by Mahmoudian et al. [66], the impact of valerian (*V. officinalis* L.) preparation on the development and functioning of mouse embryonic brain cells was explored. This research revealed that the use of valerian during the second trimester significantly reduced the levels of zinc in the embryonic brain, a critical component crucial for normal brain development [85, 93]. As a result, it is advisable for pregnant women to exercise caution when considering the use of valerian products.

Furthermore, research involving thermopsis lanceolata R.Br., an expectorant, indicated that pregnant rodents exposed to this herbal medicine had offspring with reduced body weights and craniocaudal dimensions by the time they reached 20 days of age [59]. While the pups did not experience an impact on their postnatal survival rate, their sensory, motor, and emotional-motor behaviors were altered. Consequently, the use of thermopsis or any product containing it for therapeutic purposes is discouraged due to these findings.

9 Interactions Between Medications and Herbal Supplements

9.1 Use of Homeopathic Medicines During Pregnancy and the Risk of Epilepsy

Women who experience frequent seizures may become pregnant, but the scientific research on herbal remedies for epilepsy is somewhat limited. Some herbal medicines (HMs) might increase the risk of seizures, cause unwanted side effects, or interact with conventional antiepileptic drugs (AEDs). An exception is a medication derived from the *Cannabis sativa* L. species that has received FDA approval for the treatment of certain types of epileptic seizures. Specifically, cannabidiol extracted from *Cannabis sativa* has shown promise in the management of certain forms of epilepsy. Interestingly, while these cannabis preparations have been available in several other countries for some time, the United States has only recently gained access to them. These products come in various forms, with some containing additional compounds like tetrahydrocannabinol.

However, it's worth noting that cannabis use during pregnancy has been associated with adverse effects on both the mother and the fetus, as pointed out by Gunn et al. [32]. Furthermore, in vitro studies have shown that cannabidiol inhibits several cytochrome enzymes, including CYP3A4, CYP3A5, and CYP2D6, while inducing CYP1A1 [52]. Additionally, these studies have demonstrated that cannabidiol activates the UDP-glucuronosyltransferases UGT1A9 and UGT2B7, as highlighted by Yamaori et al. [121–123]. These complex interactions could affect the processing of AEDs and may lead to treatment failures or adverse effects, altering the levels of these medications in the bloodstream. Notably, antiepileptic drugs such as clobazam, rufinamide, topiramate, zonisamide, and eslicarbazepine have been found to interact with cannabidiol, as reported by Gaston et al. [30].

While some herbal medicines are used during pregnancy, there is less scientific evidence to support their use compared to their application in treating epileptic patients. Additionally, the pharmacokinetics of various antiepileptic drugs are intricate, and they may interact with other drugs or herbal medicines in ways that can influence the course of treatment. Herbal medicines commonly used by individuals with epilepsy include St. John's Wort (*Hypericum perforatum* L.), *Ginkgo biloba* L., *Borago officinalis* L., *Valeriana officinalis* L., and *Cannabis sativa* L., as indicated by Liu et al. [63].

9.2 Pregnancy-Related Hypertension and the Use of Herbal Medicine

Pregnancy can lead to various forms of hypertension, including chronic, prenatal, preeclamptic, and chronic hypertension with concurrent preeclampsia, as noted by Lai et al. [61]. Pregnancy-related hypertension is one of the major causes of maternal and fetal illness and mortality during pregnancy, as highlighted by Mustafa et al. [74]. Preeclampsia, characterized by the onset of hypertension and proteinuria after 20 weeks of pregnancy, is on the rise, particularly among older women and those with underlying medical conditions [74, 115]. Townsend et al. [115] further emphasize that preeclampsia poses a significant risk for preterm birth and maternal mortality. Moreover, it can have detrimental effects on various bodily systems, including the renal, liver, neurological, cardiovascular, and nervous systems (e.g., eclampsia, cerebral blood clots, and bleeding, acute fatty liver of pregnancy, hepatic periportal inflammation, glomerular endotheliosis, and acute kidney injury).

Managing pregnancy-related hypertension is essential to reduce the risk of complications, including renal damage. One of the antihypertensive medications used for cases of mild to severe hypertension is labetalol [21]. It is important to avoid angiotensin-converting enzyme inhibitors during pregnancy, and alternative medications like methyldopa and nifedipine are recommended [21].

In 2017, the American College of Obstetricians and Gynecologists (ACOG) released updated recommendations for the management of sudden-onset significant hypertension during pregnancy based on the best available data [21]. Sublingual nifedipine with immediate release is the first-line treatment for pregnant women with abrupt-onset hypertension. In cases where immediate treatment is needed, hydralazine or labetalol administered intravenously are also options [21]. Most pregnant women are prescribed either nifedipine or labetalol.

The metabolic pathways of these medications differ. Nifedipine is metabolized in the body into pyridine and nifedipine carboxylic acid, primarily through the enzyme CYP3A4 [124]. Labetalol, on the other hand, undergoes significant metabolic changes in the human liver and intestines. According to Jeong et al. [51], glucuronidation, mainly mediated by enzymes UGT1A1 and UGT2B7, plays a central role in the elimination of labetalol. This process results in the formation of two inactive drug substances known as alcoholic glucuronide and o-phenyl glucuronide.

It's important to be aware that the use of herbal medicines by pregnant women, whether under medical supervision or not, can potentially alter the way these drugs are metabolized.

9.3 Using HM During Pregnancy and Asthma

Asthma is a respiratory condition that impacts the bronchial airways of the lungs, and it is estimated to affect approximately 4–8% of pregnant women [73, 76, 86]. Inadequate management of asthma during pregnancy has been associated with adverse outcomes for both the mother and the infant. These maternal outcomes may include conditions such as hypertension, gestational diabetes, preterm delivery, and even maternal mortality. Similarly, infants of mothers with poorly controlled asthma may experience fetal malformations, illness, and, in severe cases, even mortality. Multiple studies have provided evidence supporting these associations [11, 69].

Research conducted by Al Ghobain et al. [9] and McLaughlin et al. [69] underscores the importance of effectively managing asthma during the perinatal period, showing that this leads to better outcomes for both mothers and their children. Consequently, the US Department of Health and Human Services (HHS) recommends giving high priority to pregnancy-specific asthma treatment. The primary focus of such treatment is to keep the airways open, reduce the need for short-acting inhaled beta2-agonists, and minimize the risk of severe exacerbations, which helps protect both the mother and her infant from experiencing low oxygen levels.

Standard daily asthma management during pregnancy often involves a combination of medications. This includes the use of a long-acting beta-agonist like salmeterol or formoterol, a leukotriene receptor antagonist such as montelukast or zafirlukast, and a short-acting beta2-agonist like albuterol. In some cases, systemic corticosteroids like prednisone, prednisolone, or methylprednisolone may be prescribed. Additionally, healthcare providers may recommend the use of methylxanthines like theophylline or 5-lipoxygenase inhibitors like omalizumab or cromolyn as part of the treatment regimen [75, 76].

10 Conclusion

Pregnant women and their healthcare providers must make informed decisions regarding the use of pharmaceuticals or natural remedies. However, the safety and efficacy of many plant-based treatments during pregnancy remain poorly documented, often relying on anecdotal evidence. In some cases, herbal remedies might offer alternatives to invasive medical procedures, potentially reducing complications associated with malnutrition. Natural remedies like black haw and false unicorn could help save fetuses that might otherwise be lost. Compared to hospital inductions, herbal labor induction methods may provide pregnant women with a greater sense of control during childbirth.

The herbal remedies discussed here deserve increased attention for their potential to assist expectant mothers and their caregivers in achieving safe, healthy pregnancies and satisfying birthing experiences. Nevertheless, natural treatments should be approached with a degree of skepticism. Recommendations for any medication, whether natural or synthetic, should be founded on comprehensive laboratory research and clinical trials.

The combination of herbal medicines (HMs) or other natural products with conventional medications during pregnancy raises growing concerns, particularly due to our limited knowledge of potential interactions and associated risks. Many pregnant women use HMs without consulting their healthcare providers, despite the documented positive outcomes HMs can have on maternal and infant health before, during, and after pregnancy. The common assumption that HMs are inherently safe can lead to unintended consequences.

Both pregnant women and medical professionals would benefit from enhanced education and a shift away from the misconception that HMs are universally harmless. There is a real risk of interactions between HMs and traditional over-the-counter medications. For example, pregnant women taking aspirin and HMs with antiplatelet properties face an elevated risk of hemorrhage, which can, in severe cases, lead to fatal consequences. The lack of research in this area is a significant concern, as little is known about the effects of HMs on fetal development and the potential adverse reactions when combined with conventional medications.

Moreover, the potential for medication interactions can significantly compromise the management of certain medical conditions during pregnancy, such as hypertension, asthma, and seizures. The reluctance to conduct research during pregnancy makes it challenging to determine the optimal medication dosage for a woman in her third trimester, especially when she is concurrently using HMs that may interfere with the effectiveness of conventional treatments. Equally concerning is the lack of study into the embryotoxic effects of HMs. Clinical pharmacologists, scientists, and healthcare providers should strive to better understand the results of experimental and clinical research concerning the harmful effects of HMs on fetal development.

Acknowledgments We would like to extend our sincere appreciation and gratitude to the Department of Agronomy at the School of Agriculture at Lovely Professional University, Punjab, 144411, India.

Abstract

Rheumatoid disorder is a chronic inflammatory disorder of the joints that causes discomfort, inflexibility, swelling, deformity, and sometimes disability. Its cause remains a mystery. The severity of irreversible joint degradation may be mitigated with early diagnosis and therapy with disease-modifying anti-rheumatic drugs, as recommended by the American Academy of Rheumatology. Although effective treatments were quickly identified, harmful side effects often undermine their effectiveness. Herbal treatments are gaining in popularity and effectiveness for several forms of arthritis. According to a recent US poll, 90% of people with rheumatoid arthritis use complementary therapy, like herbal medications. The evidence for herbal treatments for four prevalent arthritic conditions back pain, fibromyalgia, osteoarthritis, and rheumatoid arthritis is briefly reviewed in this chapter. Some plants commonly used for the prevention or therapy of rheumatoid disorder are *Zingiber officinale*, *Piper methysticum*, *Ephedra* sp., *Oenothera biennis*, *Panax ginseng*, *Ginkgo biloba*, *Allium sativum*, *Ganoderma lucidum*, *Tripterygium wilfordii*, *Uncaria tomentosa*, *Boswellia serrata*, *Tinospora cordifolia*, *Tinospora cordifolia*, *Tribulus terrestris, Curcuma longa*, *Caesalpinia sappan*, *Clematis mandshurica*, *Rosmarinus officinalis, Elaeagnus angustifolia, Crocus sativus*, *Camellia sinensis*, *Matricaria chamomilla*, *Punica granatum*, *Cinnamomum cassia*, *Centella asiatica*, *Phyllanthus amarus*, *Psidium guajava*, *Moringa oleifera*, *Nigella sativa*, *Cannabis sativa*, *Andrographis paniculata*, *Artemisia annua*, and *Piper betle*. The possibility of treating rheumatic diseases using these plants as well as the chemical components that have this impact will be discussed in silico, in vitro, in vivo, and in clinical terms.

WT	Wild type

1 Introduction

Rheumatic illnesses include fibromyalgia, osteoarthritis, and rheumatoid arthritis (Fig. 1). Rheumatic disorders are associated with decreased productivity, substantial disability, and diminished quality of life [1]. Conventional treatment for rheumatic

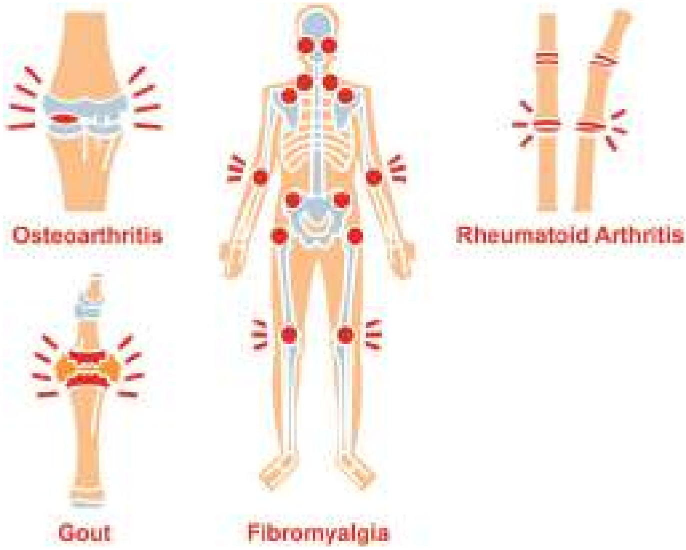

Fig. 1 Rheumatic disorders

disorders usually uses disease-modifying anti-rheumatic drugs (DMARDs), non-steroidal anti-inflammatory drugs (NSAIDs), and biologics. Some individuals may not react well to these conventional therapies. Thus, people with rheumatic illnesses usually seek alternative and complementary treatments (CAM) [2–4].

According to the World Health Organization, complementary and alternative medicine includes a wide variety of healthcare practices that are not integrated into the mainstream healthcare system and are not part of the country's tradition [5]. Under the guise of complementary and alternative medicine, a range of methods may be utilized to prevent or treat illnesses. Five groups can be used to categorize complementary and alternative medical practices, such as acupuncture, homoeopathy, herbal remedies, dietary ingredients, or additions derived from nature [6]. Around 60–90% of rheumatoid arthritis patients have employed complementary and alternative therapy, according to prior studies [7].

Prevention techniques for rheumatoid arthritis are classified as primary, secondary, or tertiary interventions. The objective of primary prevention is to prevent the onset of illness by removing particular risk factors and boosting an individual's resistance to the condition. The purpose of secondary prevention is to slow the development of a disease from its latent or asymptomatic phase to its symptomatic phase. Hence, a secondary preventive intervention aims to thwart the processes of disease development before they manifest as a disease. Cancer screening programmes such as mammography and colonoscopies are examples of this strategy. Tertiary prevention has the purpose to postpone or mitigate the effects of a disease that has already taken hold. Here is where the majority of rheumatic illnesses are being treated, with rheumatologists seeking to avoid the progression of the disease to a disability or early death when a patient presents with clinically evident disease (swollen joints in RA, or skin rash in SLE) [5].

The therapeutic objectives for rheumatoid arthritis are to lessen symptoms, stop the disease's progression, and improve quality of life. The conditions considered include analgesic relief, inflammation reduction, articular structure protection, function maintenance, and systemic involvement control before starting rheumatoid arthritis treatment [8].

This chapter examines various traditional herbs from China, India, and other Asian nations that are used as arthritis treatments. It also will go into greater detail about in silico, in vitro, in vivo, and clinical trial research on arthritis-curing plants. The data are gotten by searching the keyword (clinical study, herbal medicine, in silico, in vitro, in vivo, rheumatoid) at Google Scholar, PubMed, and other Internet sources.

2 Herbal Medicine

Herbal medicine is generally defined as a raw material or a preparation derived from plants with a therapeutic or medicinal effect that benefits human health. Herbal medicine is composed of raw materials or materials that have gone through further processing from one or more plant species. Below are some plants that have benefits as herbal medicine.

2.1 *Zingiber officinale*

Zingiber officinale (ginger) belongs to the Zingiberaceae family and has numerous advantages because of its compounds. In in silico studies, their bioactive compounds 8-gingerol, 6-gingerol, and zingerone had the potential to be inhibitors of several rheumatoid arthritis proteins [10]. These compounds carried out molecular binding on several rheumatoid arthritis protein targets, namely, cyclooxygenase-2 (COX-2), interleukin-1β (IL-1β), macrophage colony-stimulating factor (MCSF), matrix metalloproteinases-9 (MMP-9), and tumour necrosis factor-alpha (TNF-α) proteins (Fig. 2) [2]. An in vitro experiment utilizing the aqueous extract of ginger at 125 g/ml revealed that its anti-inflammatory activity was higher than diclofenac (58% vs. 52%) at the same concentration. In another study, prostaglandin-E2 (PGE2), IL-6, and IL-8 were inhibited by the 1 g/ml of ginger ethanol extract on the mRNA expression of inducible nitric oxide synthase (iNOS) and COX-2 in Caco-2 adenocarcinoma cells [11]. Rats were induced by I/R and fed once per day for 3 days in a row before the application of 6-gingerol (1, Fig. 5) from *Zingiber officinale* Roscoe extract. When administered orally at 25 and 50 mg/kg BW, the interleukin-1 and 6 and TNF-α were found to be at lower levels, as was the neutrophil count [12]. Expression of IL-12 and TGF-α in the central nervous system and serum was shown to decrease when ginger essential oil was given to experimental autoimmune encephalomyelitis (EAE) mice at 200 and 300 mg/kg [13]. In different clinical trial, it was discovered that ginger, either by itself or in combination with *Echinacea* extract (15 patients over 60 years old, 25 mg of ginger, and 5 mg of *Echinacea* extract for 30 days), considerably reduced knee discomfort [9].

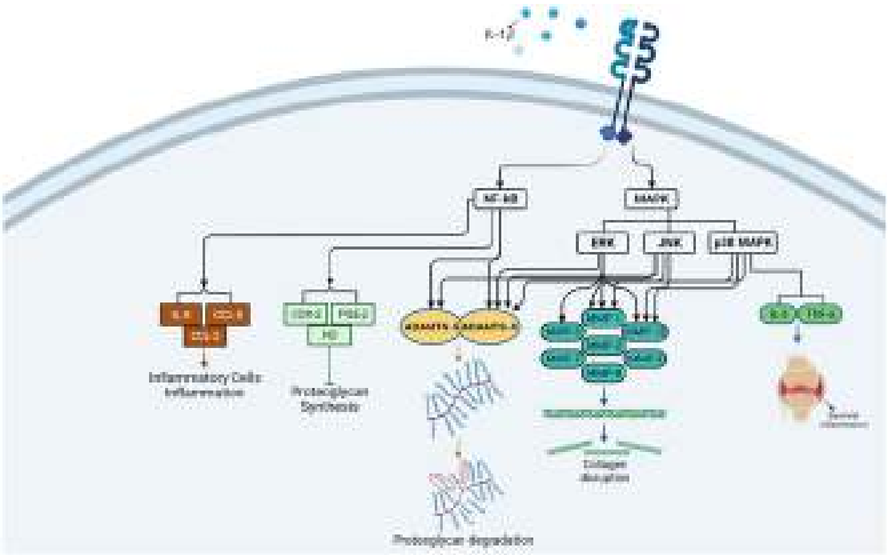

Fig. 2 Mechanism of rheumatic arthritis that is influenced by several protein targets [9]

2.2 *Piper methysticum*

Piper methysticum (kava) is a plant originating from Papua, Indonesia. Their bioactive compounds include alkaloids, flavonoids, tannins, saponins, anthraquinones, and essential oils. Based on the outcomes of molecular docking of the side chain with the morpholine ring occupying the polar domain and ring, one of the compounds from this plant showed action in suppressing iNOS protein is known as protein data bank (PDB) ID: 3E67 [10]. In in vitro investigation of nitric oxide (NO) inhibitory generation, this extract had an inhibition rate of 84.0% at a dose of 10 mM (IC_{50} 14 6.4 M) with the least amount of cytotoxicity (Fig. 3). In addition, the kavain (2, Fig. 5) in this extract significantly reduced TNF-α production induced by *E. coli* lipopolysaccharide (LPS) in primary macrophages of WT mice. In in vivo evaluation, this compound also has a significant anti-inflammatory effect on mice-induced CAIA (collagen antibody-induced arthritis) [14].

2.3 *Ephedra* Sp.

A herb known as *Ephedra* is frequently used in traditional medicine to treat fever, headaches, cough, and shortness of breath. *Ephedra alte* contains β-sitosterol (3, Fig. 5) and androstan-3-one efficiently inhibited inflammation and reduced oxidative stress by inhibiting five target proteins such as IL-6, toll-like receptor-4 (TLR4) hybrid, TNF-α, TLRs, and IL-1β. Fresh chicken egg albumin denaturation

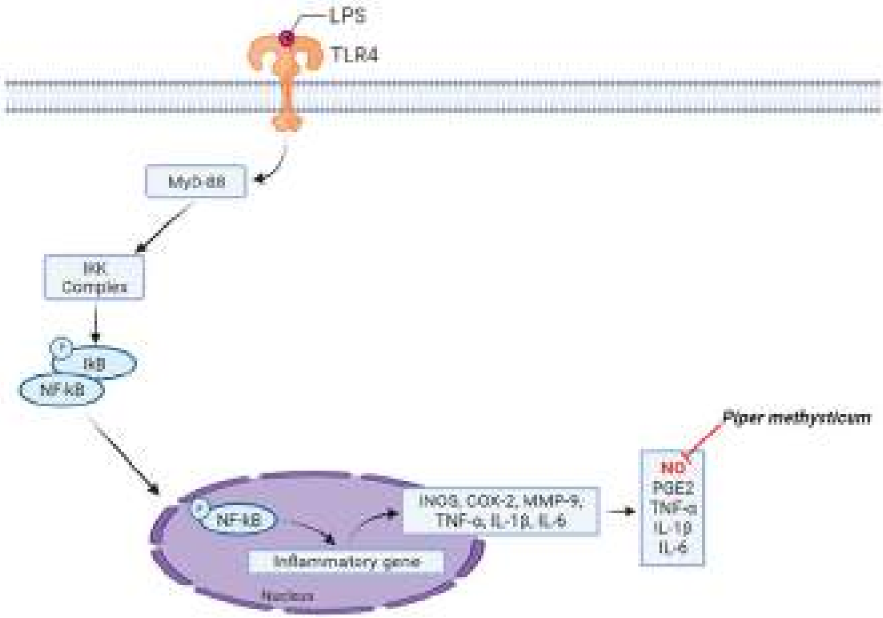

Fig. 3 Mechanism of *Piper methysticum* in inhibiting NO in RAW 264.7 cells

and membrane stabilization were performed on ethanol, ethyl acetate, n-butanol, and aqueous extracts of *Ephedra gerardiana* at 6400 μg/mL in vitro experiments involving bovine serum albumin (BSA) inhibition tests. Their aqueous extract exhibited the greatest inhibitory impact (98.5%). Then n-butanol and ethyl acetate inhibited 92.1 and 85.7%, respectively. Meanwhile, the ethanol extract with the same concentration showed an inhibitory effect of 99.1%. All extracts showed better inhibitory effect results compared to aspirin (80.5%) [15]. In other species, extracts of *Ephedra alata* and *Ephedra fragilis* inhibited NO in RAW cells 264.7 by 62% and 70% at 50 mg/mL, respectively [16]. ESP-B4 (an acidic hetero-polysaccharide) derived from *Ephedra sinica* also demonstrated reduced LPS-induced cytokine production. Moreover, pre-treatment with ESP-B4 greatly reduced the phosphorylation of mitogen-activated protein kinases (MAPKs) brought on by LPS [17]. *Ephedra gerardiana* at 200 mg/kg reduced leg volume and diameter in formaldehyde-induced rats [18]. To cure rheumatoid arthritis, it has been demonstrated that the ESP-B4 from *Ephedra sinica* inhibited the TLR4 signaling pathway, which reduces the production of inflammatory agents and cytokines [17]. This plant activity in rats given Freund's complete adjuvant was examined (FCA). Rat foot oedema can be reduced and haematological and biochemical alterations were greatly improved by this extract. Moreover, in all extracts-treated mice, the overproduction of pro-inflammatory cytokine was markedly reduced. Nonetheless, there was a significant rise in IL-4 and 10 [18].

2.4 *Oenothera biennis*

NO, TNF-α, IL-1, and thromboxane B2 (TXB2) production can be reduced by the sterol components found in *Oenothera biennis* oil or evening primrose oil (EPO). Sterols do not, however, lower PGE2 [19]. TNF-α, IL-6, and IL-1 were significantly inhibited by this extract in peritoneal macrophages (PMs), and extracellular signal-regulated ERK signaling, P38 of MAPK, and LPS-activated NF-kappaB (NF-kB) were also inhibited by *Oenothera biennis* L. [19]. A study of the arthritic group's response to EPO revealed a substantial decrease in body weight and an increase in the ankle, plasma angiopoietin-1, and TNF-α [20]. In arthritic rats, EPO increased platelet count, white blood cell count, and high ankle diameter. EPO therapy significantly reduced the levels of inflammatory biomarkers in arthritic animals, including rheumatoid factor, TNF-α, IL-1β, and IL-6. As measured by disease activity score-28 (DAS28), IL-17, tacrolimus (TAC), rheumatoid factor (RF), and C-reactive protein (CRP) values after 3 months in clinical studies on 90 rheumatoid arthritis patients who received EPO 500 mg/TDS, the results might lessen DAS28 score and severity of rheumatoid arthritis patients [21].

2.5 *Panax ginseng*

With binding affinities of −7.58 and −7.89 kcal/mol for NF-kB protein, the ginsenoside (4, Fig. 5) derived from *Panax ginseng* has an anti-inflammation medicinal agent. Moreover, it reduced the reactive oxygen species (ROS) in anti-inflammatory experiments utilizing an in vitro model of NF-kB in RAW 264.7 macrophages activated by LPS [22]. It boosted the expression of early and late-stage differentiation markers (alkaline phosphatase, collagen type-I, and osteocalcin) during osteoblast differentiation on MC3T3-E1 cells that were exposed to H_2O_2. It also decreased the overexpression of pro-inflammatory cytokines such as IL-1, NO expression, and ROS generation [23]. Ginsenoside also suppresses osteoclastogenesis in human CD14+ cells [24]. In IL-1-stimulated chondrocytes, ginsenoside Rg3 increased the expression of aggrecan and collagen type 2 (COL-II), two chondroprotective proteins, while decreasing MMP-1 and MMP-13 [25]. A mouse model of osteoarthritis was used to demonstrate that ginsenoside Rg5 dramatically ameliorated osteoarthritis symptoms by decreasing cartilage breakdown and cell death. Whereas other research demonstrated that 15 mg/kg of ginsenoside-Rg5 orally for 1 month lowered levels of IL-1, TNF-α, NO, and iNOS by 67, 54, 32, and 49%, respectively [26]. Ginsenoside Rg1 administration to osteoarthritis mice attenuated cartilage degradation and lowered the loss of type II collagen and MMP-13 levels [27]. In the joints of collagen-induced arthritis (CIA) mice treated with *Panax ginseng*, pro-inflammatory cytokines including IL-17, IL-6, TNF-α, and IL-1 were significantly reduced [28]. Fifty-two postmenopausal women with a diagnosis of degenerative arthritis of the hand and symptoms of oedema and pain in the hands had therapy with 3 g red ginseng daily for 12 weeks, then both blood oestradiol and endometrial thickness were unaffected by ginseng [28, 29]. It had considerably elevated serum OC concentrations and a dramatically decreased DPD/OC ratio, which represents bone resorption and bone formation. Twelve weeks of treatment greatly alleviated knee arthritis symptoms [30].

2.6 *Ginkgo biloba*

Ginkgo biloba is a plant from the Ginkgoaceae family and is classified as a phytopharmaceutical or medicine. It had a potential effect as an anti-inflammatory based on its ability to bind to each target protein (such as COX-2, iNOS, TNF-α, TLR-4, and IL-1β) by forming H-bonds and hydrophobic interactions [31]. In addition, *Ginkgo biloba* extract inhibited IL-1-induced chemokine synthesis, as evidenced by a decrease in THP-1 cell motility to the cell culture medium and a decrease in IL-1-stimulated iNOS expression and NO release [32]. The presence of bilobalide in *Ginkgo biloba* extract had a crucial role in suppressing the synthesis of iNOS, COX-2, and MMP-13 in ATDC5 chondrocytes stimulated by IL-1, decreasing the activity of ECM-degrading enzymes, and increasing the expression of cartilage anabolic protein [33–35]. The ginkgolide C inhibited the release of pro-apoptotic factors and stimulates the release of anti-apoptotic proteins that are produced by H_2O_2. This substance inhibited the production of MMP-3 and MMP-13, ADAMTS, and iNOS. ECM breakdowns via inhibiting Cox-2 and SOX-9 [36].

In mice models of osteoarthritis produced by ACLT, ginkgolide C had been shown to suppress joint discomfort, cartilage degradation, and aberrant subchondral bone remodeling [37]. Moreover, bilobalide inhibited the development of aberrant osteophytes in the subchondral bone and stopped the degeneration of cartilage after trauma [38]. The ginkgolide B reduced blood levels of IL-1, IL-6, MCP-1, TNF-a, MMP-3, and MMP-13 and increases IL-10 [34]. In clinical studies, *Ginkgo biloba* extract treatment for 6 weeks in 51 OA patients had much greater benefits than glucosamine/chondroitin [39, 40].

2.7 *Allium sativum*

Allium sativum is commonly used as a medicinal plant. Based on its bioactive constituents (S-allyl cysteine, polyphenols, and flavonoids), this plant has anti-inflammatory properties. In in silico testing, the presence of the pyridoxamine from *Allium sativum* inhibited all receptors except NT5C2-1497 against the four target proteins (XO, ADA, GDA, and NT5C2-1498). It indicated that the substance has the potential to be employed as an anti-gout agent [37]. Meanwhile, in a study using *Allium sativum* methanol extract, it was shown that the extract had the highest inhibition value at 100 μg/ml of 88.5% in denaturation protein egg albumin and 61.2% in bovine serum albumin [41]. This plant also showed regulation of the IL-17 gene which significantly did not influence cell proliferation and lymphocyte proliferation (T CD4+ and CD8+) [42]. In a mouse model of arthritis, treatment with

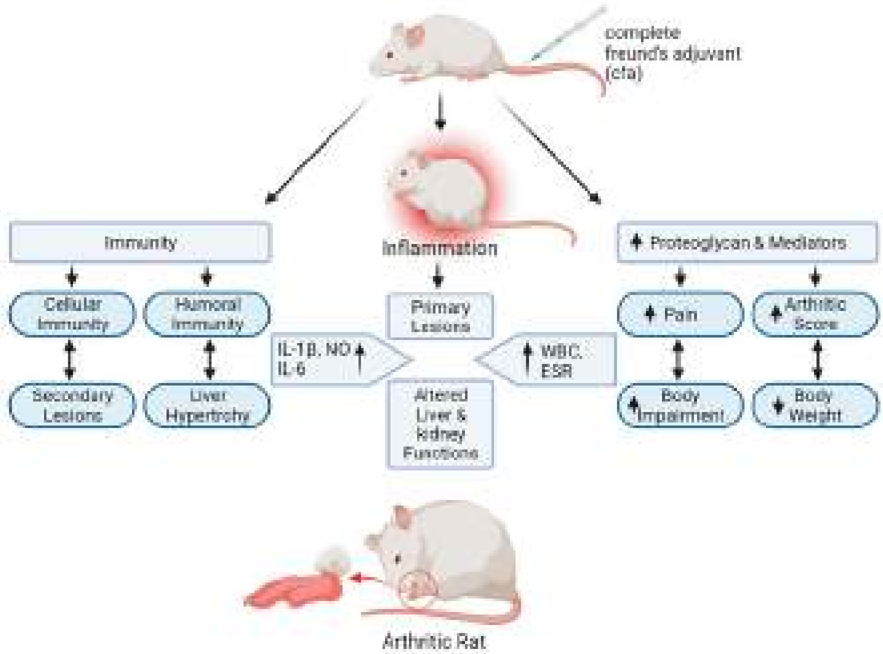

Fig. 4 Mechanism and pathway of CFA-induced arthritis [44]

100 M diallyl trisulfide suppressed the production of pro-inflammatory cytokines and regulated immunological activity by restoring the balance between Th17 and Treg cells [39]. In addition, administration of diallyl disulfide (20 and 50 mg/kg) in a CFA rat model of rheumatoid arthritis (Fig. 4) induced a significant decrease in leg volume and oedema formation; this compound also reduced inflammation, decreased white blood cell count, and increased RBC count in CFA-induced mice [40]. Seventy women with rheumatoid arthritis were separated into two groups for a clinical experiment, with one group receiving 1000 mg of garlic and the other receiving a placebo for 8 weeks. The results showed that serum C-reactive protein decreased significantly, pain intensity also decreased decreases, and the number of swollen joints also decreased [43].

2.8 *Ganoderma lucidum*

Ganoderma lucidum is a medical mushroom that contains triterpenoids, β-glucan, sterols, coumarins, mannitol, organic germanium, vitamins, flavonoids, and minerals. In silico sterol from this plant was directly bound actively to p38 and p65 to suppress their activation [45]. Furthermore, sterol has a crucial role in reducing inflammation in macrophages, as it may greatly reduce LPS-induced cell polarization and the production and expression of mRNA from pro-inflammatory mediators such as NO, TNF-α, IL-1, and 6 [46, 47]. *Ganoderma lucidum* extract's oil can prevent CIA-induced cartilage degradation in knee synovial membrane inflammation. The GLS oil group demonstrated a significant drop in knee eosinophils, and this oil lowered IL-6 mRNA expression. *Ganoderma lucidum* at 250 mg/kg BW was effective as an anti-inflammatory drug [48]. Clinically, this plant had an analgesic effect for patients with active rheumatoid arthritis, which is generally safe and well tolerated due to demonstrated activities, including significant antioxidant, anti-inflammatory, or immunomodulating properties [49].

2.9 *Tripterygium wilfordii*

Tripterygium wilfordii (thunder god vine) is commonly used in TCM to treat inflammatory conditions such as rheumatoid arthritis and autoimmune. Based on the structure of the CD2 protein, the triptolide derivative (5R)-5-hydroxy triptolide (LLDT-8) from this plant received the greatest docking score. This compound effectively blocked immune and inflammatory signaling pathways [46]. Another compound of tripterygium glycoside showed an anti-arthritis effect in rheumatoid arthritis therapy by initiating apoptosis in affected synovial lymphocytes or fibroblasts to prevent their proliferation, restrain Th17 cell differentiation, and inhibit angiogenesis [47]. Their alkaloids also had an anti-arthritis effect and significantly reduced leg swelling and suppress articular cartilage degeneration in CIA-induced mice. In addition, it was found that levels of IL-6, IL-8, NF-kB, and TNF-α in CIA serum mice decreased significantly [50]. Clinically, tripterygium glycosides significantly influenced the duration of morning stiffness (DMS), the number of painful joints (TJC), the number of swollen joints (SJC), the visual analog scale (VAS), the protein C-reactive (CRP), the erythrocyte sedimentation rate (ESR), and the rheumatoid factor (RF) in rheumatoid arthritis patients [51]. *Tripterygium wilfordii* extract at a single dose had a significant efficiency compared to MTX, while their combination gave a good significance than a single dose of MTX [52].

2.10 *Uncaria tomentosa*

The cat's claw plant (*Uncaria tomentosa*) is found in the peat forests of West Kalimantan, Indonesia. Some of the empirical benefits of this plant are used for ulcers, rheumatism, cirrhosis, gonorrhea, and female genital tract cancer. It contains alkaloids, flavonoids, polyphenols, triterpenoids, steroids, saponins, and tannins. This plant reduced osteoclast differentiation induced by RANKL without affecting cell viability [53]. Also, injection of this extract reduced ecto-nucleoside triphosphate diphosphohydrolase activity in mice models of CFA-induced arthritis but does not affect ecto-nucleoside triphosphate diphosphohydrolase and elevated erythrocyte adenosine deaminase activities in healthy animals [54]. In a separate study, administration of *Uncaria tomentosa* extracts decreased the RANKL/OPG ratio, an essential gene involved in osteoclast differentiation, reducing TRAP-positive cells lining alveolar bone and raising bone-specific alkaline phosphatase (BAP) and anabolic bone markers in plasma rat arthritic models [53]. Clinically, this plant was given to patients with advanced cancer for 8 weeks to improve their quality of life and reduce fatigue and inflammation that occurs [55]. During hemorrhagic cystitis (HC) in rats, quinovic acid glycoside was demonstrated to reduce oedema, bleeding, IL-1β levels, and neutrophil migration, exhibiting a protective impact on CH-induced urothelial damage, control of visceral discomfort, and reduction of IL-1 levels [56].

2.11 *Boswellia serrata*

Boswellia serrata (salai/salai guggul) is one of the components of the ancient and most famous herb in traditional Indian medicine, Ayurveda. This plant is beneficial for the treatment of arthritis, as well as diarrhoea, dysentery, ringworm, boils, and fever, according to empirical evidence (antipyretic). This plant is pharmacologically effective as an anti-atherosclerotic, analgesic, anti-inflammatory, and anti-arthritic. Boswellic acid (5, Fig. 5) and curcumin from this plant had the potential effect for anti-rheumatism as indicated by the high binding energy, which is between −8.66 and −9.67 [57]. The dry extract of this plant (0.1 μg/ml) showed pro-angiogenic activity, whereas the hydro enzymatic extract did not show any effect on the migratory capacity of endothelial cells [58]. Treatment of this extract for 21 days to CIA-induced Wistar rats altered numerous parameters, including MPO, LPO, GSH, and NO at doses 100 and 200 mg/kg BW. Furthermore, it resulted in a considerable reduction in numerous inflammatory mediators and a rise in IL-10 levels [59]. The injection of this extract at 180 mg/kg BW resulted in a rise in the rat's body weight and a decrease in knee diameter, leg thickness, ankle diameter, foot volume, and arthritis index, but the impact was less than that of the conventional cyclophosphamide medication. Clinically, a 12-day study of curcumin complex or its combination with boswellic acid improved pain-related symptoms in individuals with degenerative hypertrophic knee osteoarthritis. Curamin®, which contains *Curcuma longa* and *Boswellia serrata* extracts, improved the treatment of osteoarthritis due to the synergistic impact of curcumin and boswellic acid [60]. Similar to ibuprofen, the combination of *E. angustifolia* and *Boswellia thurifera* relieved pain and enhanced function in knee osteoarthritis patients [61]. Comparing methylsulfonylmethane (MSM) 5 g and boswellic acid (BA) 7.2 mg in 60 patients with knee arthritis revealed a statistically significant difference between the experimental group and the placebo group in the number of patients using anti-inflammatory medicines [62].

2.12 *Tinospora cordifolia*

Tinospora cordifolia (gurjo) is a traditional medicinal herb having anti-inflammatory properties that use to treat rheumatism, gout, bruising, fever, and stimulating hunger.

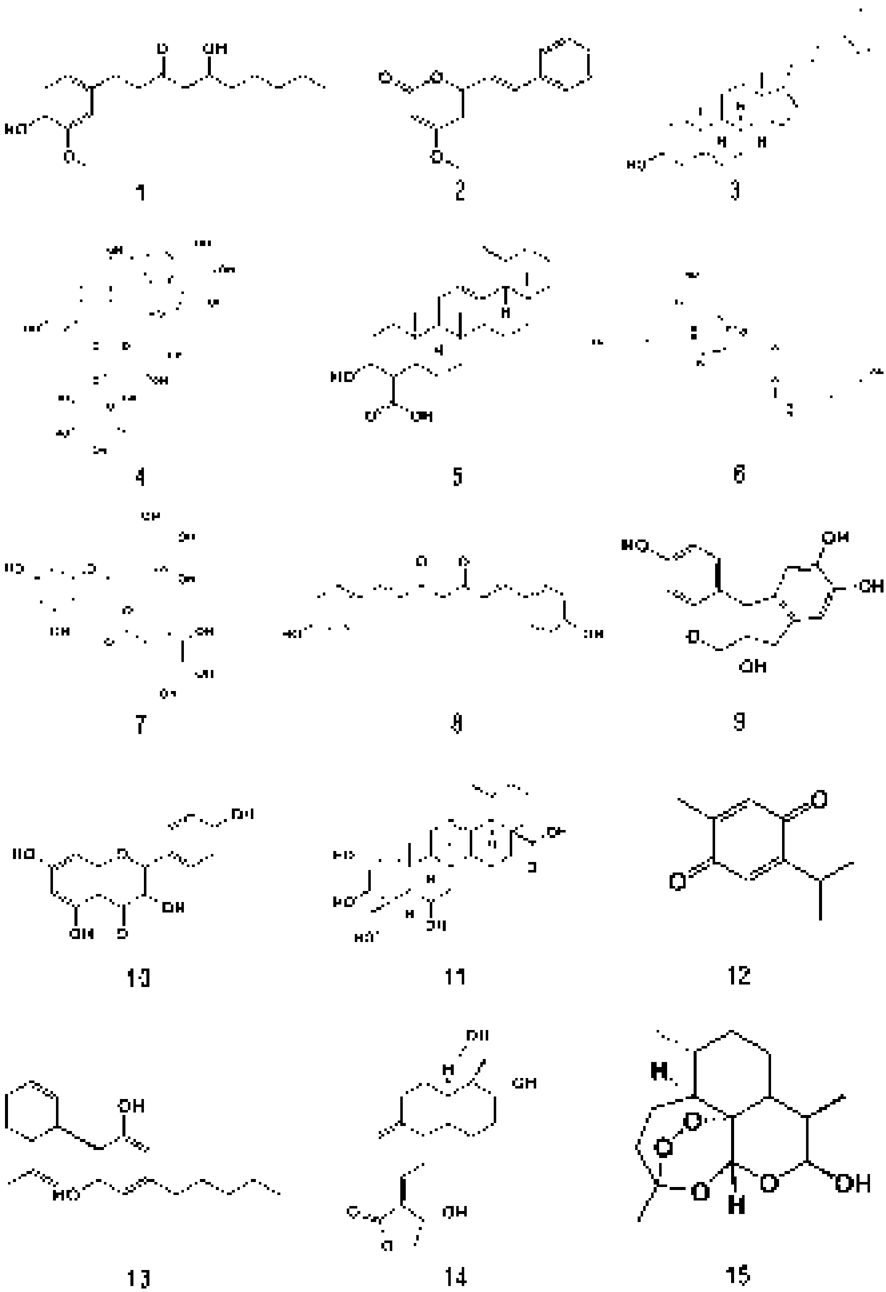

Fig. 5 Structure of chemical compounds that have the potential for anti-rheumatoid disorders therapy

It contains alkaloids, saponins, glycosides, tannins, polyphenols, flavonoids, picroretin, berberine, tinocrisposide, and columbin. This plant contains a tyramine-Fe molecule that forms a complicated binding with COX-2 (COX 2-tyramine Fe) [63]. Their extract increased the expression of genes that regulate osteoblastogenesis and mineralization, such as type I collagen, alkaline phosphatase, bone sialoprotein, osteopontin, osteonectin, osteomodulin, and osteocalcin, and has a positive effect on osteogenesis and bone formation [64]. Oral treatment of 50 mg/kg of *Tinospora cordifolia* extract to ovariectomized rats for 21 days prevented bone loss and suppressed osteoclast development [64]. This plant suppressed TNF-α and IL-1 and reduces NO generation in RAW cells 264.7 [65]. The chloroform extracts of this plant downregulated pro-inflammatory biomarkers in THP-1 macrophages by inhibiting NF-B nuclear translocation in THP cells [66]. Their extract considerably lowered levels of pro-inflammatory like IL-1, 6, and 17 in rat models of RA-induced arthritis. Hence, it may be inferred that the extract inhibited bone destruction by altering the ratio of mediators in bone remodeling (RANKL and MMP-9) that support anti-osteoclastic activity [67].

2.13 *Withania somnifera*

Withania somnifera (ashwagandha) is one of the endemic plants from India and is believed to improve physical and mental health as well as prevent various diseases, such as antimicrobial, immunostimulant, anti-inflammatory, anti-arthritis, antioxidant, and anti-diabetic. Their activity conducted cannot be separated from the role of the active compounds contained in this plant. Withanolide B present in the *Withania somnifera* had an excellent inhibition value of −7.8 kcal/mol for rheumatoid arthritis by targeting TNF-α through in silico analysis [68]. The ethanol extract of this plant inhibited 5-LOX (65%) in vitro with an IC_{50} of 0.92 mg/mL [69]. While their chloroform and water extracts were able to control the expression of TNF, IL-1, and IL-6 by reducing the production of iNOS and by downregulating NF and activator proteins. These extracts did not affect the expression of TNF-α. Moreover, the extract inhibited the migration of activated microglia by reducing MMP expression [70]. The alcoholic extract of this plant significantly decreased the diameter of the right leg's tarsal joint. In addition, the histology findings revealed that the joint membranes of mice administered this extract did not exhibit an inflammatory reaction [71]. Ashwagandha at a dose of 200 mg/kg has shown to minimize pannus production in rheumatoid arthritis joints [72]. Their extracts showed dose-dependent relief of disease severity based on reduced lipid peroxidation and ceruloplasmin, which lowered some serum levels of TNF-α, IL-1β, COX-1, and COX-2 [73]. Ashwagandha at 300 mg/kgBB increased the secretion of IL-10, lowered pro-inflammatory cytokines, and inhibited NF-kB activity [74]. The anti-inflammatory effect in adult zebrafish of comparable size and weight was determined by extracting fresh leaves of this plant with methanol and water. Due to phenolic acids and flavonoids, this extract can block TNF-α channels in zebrafish [75]. In collagen-induced rheumatic rats, administering root powder at 600 mg/kg body weight reduced the severity of arthritis by enhancing functional recovery of motor activity and radiological scores [76]. In a separate trial, this plant extract delayed morphine's analgesic impact. Moreover, it may inhibit hyperalgesia in the tail-flick test [77]. The anti-inflammatory effect of this root aqueous extract was investigated by measuring TNF-α, IL-1, 6, and 10 levels in rats with collagen-induced arthritis. Oral treatment of 300 mg/kg of their aqueous root extract reduced ROS and normalized MMP-8 levels in collagen-induced arthritic mice [74]. Clinically, the consumption of 500–1000 mg ashwagandha tablets by 77 patients for 8–12 weeks resulted in managing arthritis symptoms in these patients [78].

2.14 *Tribulus terrestris*

Tribulus terrestris is a member of the family Zygophyllaceae. This plant has been utilized in TCM and Ayurveda for centuries. Its pharmacological properties included anti-inflammatory, analgesic, hepatoprotective, and anti-cariogenic. Its action cannot be separated from the existence of active chemicals such as flavonoids, steroids, saponins, and alkaloids in this plant. Tribulusamide D and N trans-caffeoyl tyramine in the ethanol extract of *Tribulus terrestris* possessed anti-inflammatory activity, as indicated by the ability of the compounds to inhibit NO induced by LPS and PGE2 by reducing iNOS which can be induced and expression of COX-2. Tribulusamide D (6, Fig. 5) decreased the production of LPS-induced inflammatory cytokines, including IL-6, IL-10, and TNF-α, in RAW 264.7 macrophage-induced LPS [79]. These extracts were capable of repairing LPS and inducing excessive NO release and transcription of inflammatory cytokine genes. This plant inhibited LPS-induced increases in intracellular iNOS and NF-kB, which are responsible for cellular NO and cytokine production, respectively [80]. In vivo anti-arthritis action was proven by a substantial decrease in pro-inflammatory cytokines in an arthritic rat model treated with the extract at a dose of 200 and 300 mg/kg orally for 21 days [81]. In addition, this extract inhibited NO synthase 2, COX-2, TNF-α, and IL-6 in animals with MIA-induced OA [82].

2.15 *Curcuma longa*

Curcuma longa or turmeric is a plant that comes from the Zingiberaceae family. Traditionally, turmeric is often used as a treatment such as an antioxidant, antibacterial, anti-inflammatory, and antiviral. This plant includes important components such as curcumin, resin, curcuminoid, curcumin diglucoside, curcumin monoglucoside, sophoricoside, and epigallocatechin gallate (7, Fig. 5). Molecular docking scores and energy-energy ligand-protein interactions demonstrated that turmeric reduced TNF-α and IL-1 via strong molecular interactions [83]. The bisdemethoxycurcumin (8, Fig. 5) exhibited potent anti-inflammatory activity in conjunction with the suppression of NO, xanthine oxidase, and lipoxygenase. This chemical also inhibited the LPS-induced synthesis of COX-2, iNOS, IL-6, and TNF in RAW macrophages [84]. Turmeronol strongly inhibited the LPS-induced synthesis of PGE2 and NO, as well as the mRNA expression of the corresponding synthetic enzymes. Furthermore, this compound effectively reduced the LPS-induced mRNA and protein elevation of IL-1, IL-6, and TNF-α. Turmeronol derivates suppressed NF-kB nuclear translocation in a manner comparable to that of the NF-B inhibitor pyrrolidine dithiocarbamate, but not that of curcumin (another NF-kB inhibitor) [85]. Curcumin lowered inflammatory activity 6 h after zymosan-induced arthritis in rats. Curcumin at 1 mg/kg was more efficacious than prednisone in the first 6 h following arthritis onset. It did not have the same anti-inflammatory impact as prednisone after 12, 24, and 48 h. It was more effective than prednisone at decreasing inflammatory infiltration after 48 h, independent of the prednisone dosage employed [86]. Clinically, treatment of theracurmin containing curcumin 180 mg/day orally every day for 8 weeks considerably reduced reliance on celecoxib to the point where no adverse effects are noticed [87]. Compared to placebo, treatment with curcuminoids was linked with considerably higher decreases in WOMAC, VAS, and LPFI ratings. Curcuminoids are a safe and effective alternative therapy for OA [88]. *Curcuma longa* inhibited inflammation and had therapeutic benefits, such as a drop in VAS/WOMAC score level [89].

2.16 *Caesalpinia sappan*

Caesalpinia sappan known as secang is a member of the Caesalpiniaceae family. This plant is utilized in several nations, particularly in Southeast Asia. In Indonesia, secang is historically used as an immune-boosting and immune-maintenance herbal beverage. The part of this plant often used as herbal medicine is bark because it contains active compounds and is used in treating various diseases such as inflammation, diarrhoea, anti-osteoporosis, and other conditions. Phytochemical compounds in secang include brazilin, sappanone, cassane, and caesalpiniaphenol. Cassane cured rheumatoid arthritis via the TCR, TLR, VEGF, and osteoclast differentiation pathways, which are strongly associated with antigen recognition, inflammation, angiogenesis, and osteoclastogenesis [90, 91]. 3,7-dihydroxy-4H-chromen-4-one and 4-hydroxy-3,5-dimethoxybenzaldehyde exhibited potent inhibition of NO with IC_{50} values of 14.5 and 21.5 μM [92]. In CIA rats, brazilin (9, Fig. 5) at 10 mg/kg BW decreased the severity of acute foot oedema. Bone mineral density was considerably lower in CIA rats and appeared to rise proportionally with the administration of methotrexate and brazilin. The microstructural analysis demonstrates that brazilin reduced joint degradation, surface erosion, and enhanced bone growth. Brazilin significantly lowered blood levels of inflammatory cytokines in rats with CIA [93]. Sappanchalcone prevents chronic disease progression, leg oedema, arthritis severity, radiography, and histomorphometric alterations. Serum levels of pro-inflammatory cytokines were considerably lowered [94].

2.17 *Clematis mandshurica*

Clematis mandshurica roots are commonly used to treat inflammatory disorders such as gout, arthritis, and tetanus. This plant is traditionally used to relieve pain and fever in Korea. It contains hederagenin which inhibited the protein expression of iNOS, COX-2, and NF-kB at doses of 10, 30, and 100 μM triggered by LPS and generated NO, PGE2, TNF-α, IL-1β, and IL-6 on RAW 264.7 cells [95]. Feruloyl and iso-feruloyl derivatives at 50 mM exhibited a moderate inhibitory effect ranging from 29.3% to 38.7%, whereas the 3-carboxy-indole derivative exhibited a strong inhibitory effect with an IC_{50} of 7.7 to 12.4 mM [96]. The 5-O-isoferuloyl-2-deoxy-D-ribono lactone (5-IRL) stimulated inducible mRNA expression of COX-2 and iNOS [97]. This plant extract lowered arthritis scores relative to the control group in CIA-induced rats. Normal rats treated with this plant had no adverse effects on gut microbiota and SCFA metabolism [100]. This root extract at 0.25, 0.5, and 1 mg/mL inhibited protein expression LPS caused by iNOS, COX-2, NF-kB, and MAPKs (ERK, JNK, and p38) as well as the generation of TNF-α, IL-1β, IL-6, NO, and PGE2 [98]. The anti-oedema activity of hederagenin was demonstrated by the dependent reduction of LPS-induced mRNA levels of iNOS and COX-2 and the results of the carrageenan-induced rat hind limb oedema test. In addition, 30 mg/kg of hederagenin prevented carrageenan-induced increases in skin thickness, inflammatory cell infiltration, and mast cell degranulation [95]. Clematichinenoside significantly reduced leg swelling in AIA mice. It also increased levels of IL-10 and TGF-β1 released from ConA-activated PP lymphocytes, while decreased levels of IL-17 A and TNF-α [99].

2.18 *Rosmarinus officinalis*

Rosmarinus officinalis often known as rosemary is a member of the Lamiaceae family. This plant is utilized as traditional medicine like anti-diabetic, anti-inflammatory, and antioxidant. This plant contains carnosic acid, carnosol, and rosmarinic acid. Carnosic acid suppressed the expression of pro-inflammatory cytokines, including TNF-α, IL-1β, IL-6, IL-8, IL-17, and MMP-3, and downregulated the creation of RANKL. Moreover, it suppressed osteoclastogenesis and bone resorption [100]. The 70% ethanol extract of this plant exhibited oxidative damage and an enzymatic antioxidant defence system and anti-inflammatory effects [101]. In rats with arthritis, the aqueous extract of this plant reduced oxidative damage and enhanced antioxidant capacity by boosting GSH levels. Also, this extract decreased leg oedema, the number of leukocytes recruited in the femorotibial joint cavity, and the weight of lymph nodes and delayed the formation of subsequent diseases [102]. At 60 mg/kg, the methanol extract of this plant exerted a potentially effective anti-arthritic by controlling inflammation in an adjuvant-induced experimental model [103].

2.19 *Elaeagnus angustifolia*

Elaeagnus angustifolia or oleaster is a plant that comes from the Elaeagnaceae family. Kaempferol (10, Fig. 5) contained in this plant significantly inhibited IL-1-β-induced protein production from inflammatory mediators such as inducible iNOS and COX-2. It also inhibited general matrix-degrading enzymes (MMP-1, MMP-3, MMP-13, and a disintegrin), MMP with a thrombospondin-5 motif produced by IL-1β, hence preventing collagen II degradations [104]. The extract at a dose of 32 mg/kgBW significantly reduced serum concentrations of MMP-3 and MMP-13 [105] and at 1000 mg/kg effectively decreased leg oedema swelling [106]. In a randomized clinical trial conducted on 90 female osteoarthritis patients, this extract at 15 g/day for 8 weeks reduced serum levels of TNF-α and MMP-1 [107]. In addition, kaempferol reduced osteoarthritis symptoms with an efficacy comparable to that of ibuprofen [108].

2.20 *Crocus sativus*

Crocus sativus known as saffron is a member of the Iridaceae family and a traditional remedy for chronic disorders such as asthma, arthritis, and respiratory problems. Active chemicals found in saffron include phenolic and carotenoid compounds. The extract of this plant exhibited anti-inflammatory properties such as NO and IL-6 by murine RAW 264,7 cells. This extract possessed anti-osteoclastogenic properties by a full suppression of tartrate-resistant acid phosphatase (TRAP)-positive osteoclast production and a reduction in the expression of key osteoclast-related genes [109]. The extract administered orally at 25, 50, and 100 mg/kg BW to rats with arthritis for 47 days decreased TNF-a and IL-1 levels in CSE-2 and 3-group rats compared to rheumatic mice [110]. Dosages of 200–2000 mg/kg of saffron ethanol extract exhibited an anti-inflammatory effect of 18.2–27.8% against mice treated with 49.5% DEX (15 mg/kg) [111]. Histological scores of joint inflammation, bone erosion, chondrocyte mortality, cartilage surface erosion, and bone erosion in CIA mice treated with 40 mg/kg crocin were equal to those of normal mice. The protein expression levels of MMP-1, MMP-3, and MMP-13 in CIA mice treated with 40 mg/kg crocin were lowered to normal levels. In addition, crocin inhibited the expression of TNF-a, IL-17, IL-6, and CXCL8 in CIA rats' blood and ankle tissue [112, 113].

2.21 *Camellia sinensis*

Green tea also known as *Camellia sinensis* is one of the herbal plants frequently utilized in traditional medicine such as losing weight, lowering cholesterol, and overcoming an inflammation. This plant has several active compounds including flavones, flavonols, flavanones, catechins, and isoflavones. Epigallocatechin gallate in this plant had a bond to TNF-α of −90.90 and to the IL-1 target protein of

−120.75 [83]. This compound showed anti-rheumatoid arthritis efficacy by killing synovial fibroblast cells (66.1%), downregulating TNF-α (93.33%), IL-6 (87.97%), and inhibiting p-STAT3 (77.75%) [114]. A dose of 400 mg/kg/BB of *Camellia sinensis* extract had anti-arthritis effectiveness of 60% and boosted levels of superoxide dismutase, catalase, and glutathione by 34%, 59%, and 50% [115]. At 400 mg/kg/BB, this extract effectively reduced TNF-α, IL-1, and IL-6 levels in the joint tissue of rats. Compared to the arthritic and infected group, the therapy of this extract exhibited substantial reductions in cartilage degradation and pannus development, and there was no evidence of inflammation in the small intestine [116]. Clinically, administration of this extract for 4 weeks resulted in a significant difference in the average VAS pain score, total WOMAC, and WOMAC physical function between the green tea and control groups [117].

2.22 *Matricaria chamomilla*

Matricaria chamomilla (camomile) is a member of the Asteraceae family and used for treating stomach discomfort and sleeplessness, as well as for anti-inflammatory, antibacterial, and sedative effects. The compounds from this plant had comparable scores in the active site by the free binding energy ($\Delta G = 54.19$ kcal/mol) [118]. The extract at 400 mg/kg BW decreased blood calcium, phosphate ion, and magnesium levels by 54.01%, 27.73%, and 20%, respectively. In addition, this dose also decreased creatinine and alkaline phosphatase levels by 29.41% and 27.82%, respectively [118, 119]. Compared to diclofenac and placebo, chamomile oil greatly reduced the patient's requirement for acetaminophen. Nevertheless, there were no statistically significant changes in the WOMAC questionnaire's domains, and no adverse effects were reported by patients taking chamomile oil [120].

2.23 *Punica granatum*

Punica granatum is used as an anti-inflammatory, antibiotic, antibacterial, etc. It contains flavonoids, polyphenols, alkaloids, anthocyanins, tannins, etc. The ellagic acid derived from the *Punica granatum* could bind to NF-kB protein; however, the various binding efficiencies are examined based on the energy gained for binding and the number of hydrogen bonds generated. The calculated bond-free energy of the NF-kB-EA complex was 7.1 kcal/mol with two hydrogen bonds [121]. The 70% ethanol extract of this plant decreased IL-1-inducible, iNOS, COX-2, and MMP-13 protein production in primary mouse chondrocytes (PRC) [122]. At a dose of 50 mg/kg, the butanol fraction increased RBC and Hb while decreasing WBC and ESR [123]. The injection of 500 and 750 mg/kg of this ethanol extract for 4 weeks resulted in a reduction in paw volume; a rise in latency time and levels of ALT, AST, and ALP; and a substantial drop in RF and MDA activity compared to the rheumatism control group. The extract reduced the levels of IL-1 and TNF in rats with arthritis. Histological analysis revealed that therapy with the extract reversed greatly the histological alterations produced by arthritis [124]. Rosmarinic acid considerably decreased the severity of rheumatism, leg volume, joint diameter, white blood cell count, and erythrocyte sedimentation rate. Moreover, it dramatically boosted body mass, haemoglobin, and red blood cells [125]. In a mouse model of osteoarthritis caused by collagenase type II, POMx (150 mg/kg) reduced knee-associated inflammation and nociception and corrected alterations in the weight-bearing ratio of experimental mice [122]. In clinical studies, 250 mg of pomegranate enhanced disease activity and multiple blood indicators of inflammation and oxidative stress in individuals with rheumatoid arthritis [126]. Pomegranate juice enhanced physical function and stiffness, as well as it is antioxidant and MMP-13 inhibiting capabilities in osteoarthritis patients [127]. Women with knee OA who took 500 mg of pomegranate peel twice a day for 8 weeks saw a reduction in pain and an improvement in symptoms [128].

2.24 *Cinnamomum cassia*

Cinnamomum cassia is a plant that belongs to the Lauraceae family and is traditionally used to treat gastritis, blood circulation abnormalities, dyspepsia, and inflammatory conditions. This plant contains several active compounds such as cinnamic aldehyde, coumarin, tannin, methyl dihydromelilotoside derivative, hierochin B, balanophonin, quercetin, and luteolin that were able to interact with JAK2, mPEGS-1, COX-2, IL-1β, and PPARγ target proteins [129]. This plant possessed antipyretic, anti-inflammatory, antibacterial, anti-diabetic, and anticancer properties. The ethyl acetate fraction of this plant inhibited carrageenan-induced leg swelling in rheumatoid arthritis and LPS-induced NO generation in murine immune cells [130]. Cinnamaldehyde from this plant dramatically reduced synovial inflammation in rats with arthritis. It was related to the inhibition of IL-1β. This compound was also capable of reducing HIF-1α activity by preventing succinate build-up in the cytoplasm. This reduction inhibits IL-1β synthesis because HIF-1α promotes the expression of NLRP3, which is important in the assembly and processing of IL-1β by the inflammation. In addition, cinnamaldehyde suppressed the expression of the GPR91 succinate receptor, hence inhibiting HIF-1α activation even more [131]. Cinnamomi lactone inhibited MMP-3, IL-1β, and MMP-1 gene expression in FLS cells [132]. Stems of this plant considerably lowered MDA levels and joint swelling, accompanied by a rise in GSH levels. This extract dramatically decreased joint swelling, IL-1, and TNF levels in rats with arthritis caused by CFA. The expression of TNF-α receptors was reduced in mice treated with indomethacin or *Cinnamomum cassia* stem extract [133].

2.25 *Centella asiatica*

Centella asiatica is a plant that is often used in wound healing and contains saponins, asiaticoside, asiatic acid, and carotenoids. The 2000 g/ml of *C. asiatica* extract inhibited protein denaturation and membrane stabilization in the greatest percentages of 89.76% and 94.97%, respectively [134]. Madecassoside and madecassic acid (11, Fig. 5) directly inhibited the release of pro-inflammatory cytokines and IL-10 from CD4+ CD25+ T cells [135]. The extract dramatically reduced mechanical allodynia and hyperalgesia, spontaneous pain, and motor changes. Their efficacy was greater than or equivalent to that of the reference medication, triamcinolone acetonide (100 μg intramuscularly). The histological study of MIA+14G1862-treated rats revealed the improvement of several morphological parameters, with significantly positive effects on joint space and fibrin deposition [135]. The methanol fraction of *Centella asiatica* (150 and 250 mg/kg) considerably mitigated the severity of CIA and decreased synovial inflammation, cartilage erosion, and bone erosion, as demonstrated by histological and radiological data. The increase in plasma levels of TNF-α, IL-1, IL-6, IL-12, and NO in CIA mice was significantly attenuated by treatment with *Centella asiatica*. Serum levels of anti-collagen type-II antibodies were significantly lower in the treatment group than in the rheumatic group in rats given *Centella asiatica* (150 and 250 mg/kg) [136].

2.26 *Phyllanthus amarus*

Phyllanthus amarus is a medicinal plant that is often used to treat pain and includes the Phyllanthaceae family. Based on its pharmacological activity, this plant is often used to treat diabetes, malaria, analgesics, arthritis, and hypertension. This plant contains compounds such as filantin, hypophylantine, filantenol, nirantin, and Quercetin. In a cartilage explant model, *P. amarus* extract (PAE) and its major components, including phyllanthin and hypophyllanthin, were evaluated. Following 4 days of incubation, the DMMB binding assay and zymography were used to assess the release of sulfated glycosaminoglycans (sGAGs) and MMP-2 activity, respectively, in a culture medium. The chondroprotective potential of PAE and its major components against IL-1β-induced degradation of cartilage explants was demonstrated by decreased levels of sGAGs and MMP-2 activity in culture media, which were consistent with increased uronic acid and proteoglycan content in explants, compared to IL-1β treatment [137]. Phyllanthin considerably inhibited the compound's response to LPS-stimulated prostaglandin overproduction via a mechanism connected to the modification impact of COX-2 protein and gene expression. Moreover, phyllanthin dramatically prevented the release of mRNA and the production of IL-1ß and TNF-α. In a concentration-dependent way, phyllanthin also dramatically downregulated IκBα, NF-kB (p65), and IKKα/β phosphorylation and inhibited JNK, ERK, p38MAPK, and Akt activation [138]. In addition, the extract suppressed the synthesis of pro-inflammatory (TNF-α, IL-1β, PGE2) and the expression of COX-2 protein in LPS-stimulated U937 human macrophages. Pre-treatment of this plant also substantially inhibited the pro-inflammatory marker mRNA transcription in U937 macrophages [139].

Phyllanthus amarus extract was able to modulate the development of physical parameters (e.g. weight loss, increase in body temperature, reduction in hind limb volume, and severity of arthritis), bone mineral density, haematological and biochemical disturbances, serum cytokine production, and levels of MMPs together with their inhibitors in synovial fluid. Examination of the knee joint's histopathology demonstrated that the extract efficiently lowered synovitis, pannus development, bone resorption, and cartilage disintegration [140]. The extracts and leaves of two *Phyllanthus amarus* and *Phyllanthus fraternus* elevated the threshold for mechanical withdrawal (mechanical hyperalgesia) to return to the original reaction. The percentage of maximal achievable effectiveness and the percentage of suppression of hyperalgesia further demonstrate the efficiency of *Phyllanthus* extract [141]. In 40 OA patients, *Phyllanthus amarus* extract nanoparticles administered through phonophoresis showed a substantial rise in the visual analog scale (VAS) and 6-MWT following therapy in both groups. The phonophoresis (PP) group had a more substantial reduction in VAS pain levels and an increase in 6-MWT than the ultrasonic therapy (UT) group [142].

2.27 *Psidium guajava*

Psidium guajava is a plant that is known for its many benefits in Indonesia. The phytochemical analysis of guava leaves revealed the presence of flavonoids, saponins, tannins, phenols, carotenoids, and quercetin. In addition, epicatechin-3-O-gallate shows tremendous promise as a selective anti-inflammatory COX-2 inhibitor due to its strong bond strength and stability, as well as its low bond energy when bound to the target protein (6-COX) [143]. Guava leaf extract significantly inhibited LPS-induced production of NO and PGE2 in RAW264.7 macrophages by inhibiting the expression and activity of iNOS and COX-2 which was partially induced by the downregulation of ERK1/2 activation [144]. The ethanol extract of this leaf considerably suppressed leg oedema in the chronic phase, as measured by an increase in oedema beginning on day 20. The most beneficial dose of EEPG for lowering arthritis scores was 250 mg/kg. Histopathological analysis revealed that the knee's synovial membrane and cartilage have been repaired [145]. Extract of this leaf was also capable of reducing the number of lymphocytes and leukocytes. The group that received extract dosages of 250 and 750 mg/kg BW showed a substantial reduction in leukocytes both before and after treatment. Following administration of 250, 500, and 750 mg/kg BW of ethanol extract of *P. guajava* leaf, the number of lymphocytes was also reduced. This leaf extract at 750 mg/kg BW suppressed leukocytes and lymphocytes most effectively [146]. In the 12th week of the clinical experiment, knee pain and stiffness (a subgroup of the JKOM score) were considerably lower in the guava group than in the placebo group. Utilizing a visual analog scale (VAS) to measure knee pain, a significant correlation was seen between treatment effect and test length, with the guava group having a lower VAS score after 12 weeks than the placebo group. In conclusion, continual use of guava leaf extract can alleviate knee discomfort, indicating a possible preventative benefit against OA symptoms [147].

2.28 *Moringa oleifera*

Moringa oleifera or commonly known by the local name “moringa” is a type of plant that has various benefits. One of the potentials possessed by moringa based on phytochemical analysis (flavonoids, saponins, and polyphenols) is as an anti-inflammatory. The moringa extract inhibited the production of inflammatory cytokines (IL-1β, TNF-α, and IL-6) and the degradation of cytoplasmic IB- and nuclear translocation of p65 protein, resulting in reduced NF-kB transactivation. The moringa extract also inhibited NFk-B activation in RAW 264.7 cells, hence reducing the levels of pro-inflammatory mediators like NO, IL-1β, TNF-α, and IL-6 [148]. In vivo investigation of moringa leaf extract at 250 and 500 mg/kg in rats with arthritis showed higher inhibitory action against inflammatory leg oedema with fewer toxicity and adverse effects than the indomethacin-treated group [149]. Oral treatment of *Moringa oleifera* (25, 50, and 100 mg/kgBW) in rats induced with CFA significantly reduced joint inflammation as evidenced by reductions in joint diameter, rheumatic scores, and inflammatory cell infiltration [150]. Oral administration of *Moringa oleifera* at doses between 250 and 500 mg/kg lowered the rheumatic index and sole oedema. It is believed that moringa can reduce serum pro-inflammatory cytokines when administered [151].

2.29 *Nigella sativa*

Nigella sativa (black cumin) is one of the herbal plants that are frequently employed as a traditional medicine due to the presence of its active constituents. One of the pharmacological activities of this plant is as an anti-inflammatory. This plant produces thymoquinone (12, Fig. 5) which acts as an anti-inflammatory and anti-proliferative in osteoarthritis. This compound inhibited apoptosis-regulated signaling kinase 1 (ASK1) in response to TNF-induced activation of phospho-p38 and phospho-JNK. Moreover, TNF-α promotes ASK1 phosphorylation at the Thr845 site in RA-FLS selectively [152]. Application of this plant oil (1.82 mL/kg) to arthritic rats dramatically decreased the onset of arthritis by 56%. The oil possessed anti-inflammatory, anti-rheumatic, and analgesic properties [153]. Thymoquinone derivative considerably lowered the total leukocyte count, inflammatory clinical score, and blood urea and serum creatinine levels [154]. Clinically, therapy with *Nigella sativa* caused an increase in the number of swollen joints, as compared to the initial and placebo groups. This plant treatment led to a drop in CD8 + and a rise in the proportion of CD4+ CD25+ T cells and the CD4+/CD8+ ratio. In the NS group, a significant negative connection was identified between CD8+ change and CD4+ CD25+ T cell change [155]. *Nigella sativa* lowered the DAS28 score considerably compared to the placebo group. Serum levels of IL-10, TNF-, MDA, SOD, catalase, TAC, and NO did not alter significantly from the placebo group [156].

2.30 *Cannabis sativa*

Cannabis sativa is a plant that comes from the Cannabidaceae family and is often used as an antidepressant, for fatigue, and mental disorders. The active compounds of this plant include cannabinoids, tryptophan, and cannabidiol (13, Fig. 5). Tryptophan had an inhibition value of −5.6 against TNF-α protein compared to ascorbic acid and linoleic acid [157]. Cannabidiol contributed to the reduction of cell viability, proliferation, and RASF IL-6/IL-8 production. Moreover, pre-treatment with TNF enhanced intracellular calcium and absorption of cationic PoPo3 viability dyes in RASF [158]. *Cannabis sativa* oil decreases the survival rate of MH7A cells and induces apoptotic cell death in a dose- and time-dependent manner. In MH7A cells treated with HO, lipid accumulation and intracellular ROS increase. Then co-treatment with the antioxidant tyrone substantially negated the harmful impact of H_2O_2 on MH7A cells. The result was that ROS levels decreased, cell viability was restored, and apoptotic cell death was significantly decreased [159]. Cannabidiol increased the amount of early apoptotic B cells at the expense of viable cells and decreased the production of TNF and IL-10 when independently stimulating T cells. CBD boosted IL-10 synthesis in PBMC when B cells were triggered by T cells but decreased TNF levels when T cells were activated independently. CBD inhibited IL-10 production in PBMC/rheumatoid synovial fibroblast co-cultures when B cells were stimulated independently of T cells [160]. In a dose-dependent manner, administration of cannabidiol in a rat model of OA decreased joint oedema, limb posture score as a spontaneous pain rating, immune cell infiltration, and synovial membrane thickening. Immunohistochemical study of bone marrow (CGRP, OX42) and dorsal root ganglia (TNF-α) demonstrated a dose-dependent decrease of pro-inflammatory biomarkers, with 6.2 and 62 mg/day being effective levels [160]. Cannabidiol resulted in improvement in patient-reported outcome measures, including pain on the visual analog scale; arm, shoulder, and hand disabilities; and single-assessment numerical evaluation scores, compared to the control group in a clinical trial involving 10 patients with arthritis of the thumb. Physical metrics associated with a range of motion, grip, and pinch strength were found to be comparable [161, 162].

2.31 *Andrographis paniculata*

Andrographis paniculata popularly known as sambiloto is one of the nine most extensively used medicinal herbs in Indonesia, as well as other nations. This plant demonstrated antithrombotic, antiviral, immunosuppressive, and anti-inflammatory properties. Andrographolide is one of the primary active chemicals in this plant. This compound dose-dependently inhibited IL-1β and IL-6 release from TNF-α-stimulated RA-SFs [163]. It was effective at alleviating arthritis symptoms by reducing neutrophil infiltration and necrosis in the ankle joint, relieving systemic inflammation, accelerating LPS-activated neutrophil apoptosis, and inhibiting extracellular-dependent autophagy-dependent neutrophil formation [164]. Andrographolide (14, Fig. 5) was also capable of dose-dependently suppressing

MMP-1, 3, and 9 inhibited by these substances [165]. In in vivo experiments, andrographolide reduced blood levels of anti-CII, TNFα, IL-1β, and IL-6 to considerably reduce the severity of arthritis and joint destruction [163]. By directly targeting NF-κB, andrographolide inhibited the inducible activation of iNOS and COX-2 as indicated by immunoblot analysis [166]. Compared to mice administered dexamethasone, animals treated with andrographolide had a reduction in leg oedema, cell cytotoxicity, and NO generation [167]. Moreover, the administration of this molecule enhanced the anti-rheumatic efficacy of MTX. Combining AD and MTX decreased inflammatory symptoms in CFA mice additively. The hepatoprotective effect of AD and MTX combination treatment was characterized by an improvement in blood indicators, potentially related to antioxidant activity, and verified by histological alterations in the liver. Moreover, combination treatment substantially decreased blood levels of TNF-α, IL-6, and IL-1β [168]. On days 28, 56, and 84, individuals treated with 300 and 600 mg/day of paractin experienced significantly less discomfort than the control group. Compared to the placebo group, stiffness, physical function, and tiredness scores improved significantly in both paractin-treated groups [169].

2.32 *Artemisia annua*

Artemisia annua is a medicinal plant originating from sub-tropical regions such as China. This plant has several properties including being antimalarial, anti-inflammatory, and effective in treating autoimmune diseases. These benefits and properties cannot be separated from the role of their active compounds such as artemisinin, alkaloids, saponins, sterols, triterpenes, tannins, and coumarins. In RAW 264.7 cells, casticin and chrysosplenol D decreased the LPS-induced production of IL-1β, IL-6, and MCP-1, limited cell motility, and lowered the LPS-induced phosphorylation of IB and c-JUN. In addition, it was a JNK SP600125 inhibitor that prevents the inhibition of cytokine release by chrysosplenol D. Application of casticin and chrysosplenol D inhibited ear oedema produced by croton oil and dexamethasone in rats [170]. The dihydroartemisinin (15, Fig. 5) contained in *Artemisia annua* extract was able to inhibit bone loss in ovariectomized rats so that osteoclast formation will also be inhibited [157, 171, 172]. The clinical administration of *Artemisia annua* extract treatment at 150 and 300 mg twice a day orally for 12 weeks resulted in a substantial decrease in pain ratings and joint swelling [10].

2.33 *Piper betle*

Betel leaf (*Piper betle*) is one of the plants used in traditional medicine by the community. Betel leaves contain secondary metabolites including flavonoids, tannins, saponins, and alkaloids. Moreover, betel leaves have the potential for different therapeutic properties, including anti-inflammatory properties. The 4-allyl-1,2-diacetoxybenzene exhibited stronger interactions with less binding energy to RA targets than MMP-1(−6,4 kcal/mol), TGF(−6,9 kcal/mol), and IL-1(−5,4 kcal/mol) [173]. Betel leaf methanol extract (PBME) was able to suppress protein denaturation more efficiently than normal ibuprofen, with an IC_{50} concentration of 20.5 μg/ml compared to 17.5 μg/ml for ibuprofen [173]. Moreover, the recovery of rat joint injury demonstrates the anti-arthritic action of PBME (250 and 500 mg/kg BW). The reduction of leg oedema and rheumatic scores, backed by radiographic and histological alterations, demonstrates that combined treatment with allylpyrocatechol (APC) and MTX dramatically improved arthritic parameters. This combination inhibited the production of pro-inflammatory cytokines, such as TNF-α and IL-6. In addition, the APC-MTX combination reduced cachexia, splenomegaly, and oxidative stress associated with these conditions [174]. The use of lower (200 mg/kg) and higher (400 mg/kg) dosages of *Piper betle* extract showed a dose-dependent reduction in SGPT, SGOT, and ALP, leg volume, foot diameter, and increased body weight as compared to the rheumatism control group. Serum rheumatoid factor was significantly decreased in all treated animals. In addition, the anti-arthritic effect was validated by histology of the synovial joints of treated rats, which revealed decreased constriction of the inter-tarsal joint gaps. The acquired findings are comparable to the standard [175–179].

Medicinal plants have activity as anti-rheumatoid disorders through various mechanisms depending on their secondary metabolites. Table 1 summarizes the mechanism of anti-rheumatoid from the selected plants in this chapter of the book. Some are through the inhibition of PGE2, IL-6, IL-8, and iNOS, etc. In more detail the mechanism of action of medicinal plants as anti-rheumatoid disorders can be seen in Table 1.

3 Conclusion

Arthritis disorders are associated with reduced productivity, substantial disability, and decreased quality of life. Conventional therapies include disease-modifying anti-rheumatic drugs (DMARDs) and non-steroidal anti-inflammatory drugs (NSAIDs).

Table 1 The mechanisms of anti-rheumatoid disorders form the selected plants

Plant	Mechanism
Zingiber officinale	Aqueous extract of ginger at 125 g/ml revealed that its anti-inflammatory activity was higher than diclofenac Ethanol extract of ginger inhibit PGE2, IL-6, IL-8, and iNOS Essential oil of ginger decreasing expression of IL-12 and TGF-α
Piper methysticum	Extract of *Piper methysticum* inhibit nitric oxide (NO) Kavain compound reduce production of TNF-α
Ephedra sp.	β-Ssitosterol and androstan-3-one inhibit IL-6, TLR4, TNF-α, and IL-1β Extract of *Ephedra alata* and *Ephedra fragilis* inhibited NO *Ephedra sinica* inhibit production of cytokine

(continued)

Table 1 (continued)

Plant	Mechanism
Oenothera biennis	*Oenothera biennis* inhibit TNF-α, IL-6, and IL-1 Evening primrose oil inhibit TNF-α and reduce IL-1β, and IL-6
Panax ginseng	*Panax ginseng* reduce of reactive oxygen species (ROS), IL-1, NO expression, and ROS. Ginsenoside compound suppresses osteoclastogenesis and increased the expression of aggrecan and collagen type 2 (COL-II) Ginsenoside decreasing of MMP-1 and MMP-13
Ginkgo biloba	*Ginkgo biloba* extract inhibit IL-1, iNOS, NO, MMP-13 Ginkgolide B reduces IL-1, IL-6, MCP-1, TNF-a, MMP-3, and MMP-13 and increases IL-10
Allium sativum	*Allium sativum* regulate of the IL-17 gene
Ganoderma lucidum	Sterol compound reduce pro-inflammatory mediators such as NO, TNF-α, IL-1, and 6
Tripterygium wilfordii	Compound of tripterygium glycoside prevent their proliferation, restrain Th17 cell differentiation and inhibit angiogenesis Alkaloid compound from *Tripterygium wilfordii* decrease levels of IL-6, IL-8, NF-kB, and TNF-α
Uncaria tomentosa	*Uncaria tomentosa* extracts decreased the RANKL/OPG ratio Quinovic acid glycoside was demonstrated to reduce oedema, bleeding, IL-1β levels, and neutrophil migration
Boswellia serrata	*Boswellia serrata* extract reduce IL-10 levels *Boswellia serrata* extract altered numerous parameters, including MPO, LPO, GSH, and NO
Tinospora cordifolia	*Tinospora cordifolia* suppressed TNF-α and IL-1 and reduces NO generation Chloroform extract *Tinospora cordifolia* downregulated pro-inflammatory biomarkers in THP-1 *Tinospora cordifolia* extract lowered levels of pro-inflammatory like IL-1, 6, and 17
Withania somnifera	Chloroform and water extracts *Withania somnifera* were able to control the expression of TNF, IL-1, and IL-6, COX-1, and COX-2
Tribulus terrestris	Ethanol extract of *Tribulus terrestris* inhibit NO induced by LPS and PGE2 Tribulusamide D compound decreased the production of LPS-induced inflammatory cytokines, including IL-6, IL-10, and TNF-α, in RAW 264.7
Curcuma longa	Bisdemethoxycurcumin compound suppresses NO, xanthine oxidase, and lipoxygenase and inhibits COX-2, iNOS, IL-6, and TNF Turmeronol compound inhibited the LPS-induced synthesis of PGE2, NO, IL-1, IL-6, and TNF-α
Caesalpinia sappan	Cassane compound cured rheumatoid arthritis via the TCR, TLR, VEGF, and osteoclast differentiation pathway 3,7-dihydroxy-4H-chromen-4-one and 4-hydroxy-3,5-dimethoxybenzaldehyde exhibited potent inhibition of NO
Clematis mandshurica	Hederagenin inhibited the protein expression of iNOS, COX-2, and NF-kB Clematichinenoside compound significantly increase level of IL-10 and TGF-β1
Rosmarinus officinalis	Carnosic acid compound suppressed the expression of TNF-α, IL-1β, IL-6, IL-8, IL-17, and MMP-3.

(continued)

Table 1 (continued)

Plant	Mechanism
Elaeagnus angustifolia	Kaempferol compound significantly inhibited IL-1β, MMP-1, MMP-3, MMP-13
Crocus sativus	*Crocus sativus* extract inhibit NO and IL-6 *Crocus sativus* extract decreased TNF-a and IL-1 levels Crocin compound inhibited the expression of TNF-a, IL-17, IL-6, and CXCL8
Camellia sinensis	Epigallocatechin gallate compound killing synovial fibroblast, downregulating TNF-α, IL-6 and inhibiting p-STAT3
Matricaria chamomilla	*Matricaria chamomilla* extract decreased blood calcium, phosphate ion, and magnesium levels
Punica granatum	70% ethanol extract of *Punica granatum* decreased IL-1-inducible, iNOS, COX-2, and MMP-13 Ethanol extract *Punica granatum* reduced the levels of IL-1 and TNF
Cinnamomum cassia	Compound from *Cinnamomum cassia* were able to interact with JAK2, mPEGS-1, COX-2, IL-1β, and PPARγ target proteins Cinnamaldehyde inhibit IL-1β, reducing HIF-1α Cinnamomi lactone inhibited MMP-3, IL-1β, and MMP-1
Centella asiatica	Madecassoside and madecassic acid directly inhibited the release of pro-inflammatory cytokines and IL-10 *Centella asiatica* extract reduce TNF-α, IL-1, IL-6, IL-12, and NO
Phyllanthus amarus	*Phyllanthus amarus* extract decreased levels of sGAGs and MMP-2 Phyllanthin compound reduce IL-1ß and TNF-α
Psidium guajava	Guava leaf extract inhibited LPS-induced production of NO and PGE2
Moringa oleifera	The moringa extract inhibited the production of inflammatory cytokines (IL-1β, TNF-α, and IL-6) The moringa extract also inhibited NFk-B and reducing NO, IL-1β, TNF-α, and IL-6
Nigella sativa	Thymoquinone compound inhibited apoptosis-regulated signaling kinase 1 (ASK1) in response to TNF-induced activation of phospho-p38 and phospho-JNK *Nigella sativa* led to a drop in CD8+ and a rise in the proportion of CD4+ CD25+ T cells and the CD4+/CD8+ ratio
Cannabis sativa	Cannabidiol compound contributed to the reduction of cell viability, proliferation, and RASF IL-6/IL-8 production Cannabidiol decreased the production of TNF and IL-10 Cannabidiol boosted IL-10 synthesis
Andrographis paniculata	Andrographolide compound inhibited IL-1β and IL-6 Andrographolide suppressing MMP-1, 3, and 9 Combination of andrographolide and methotrexate substantially decreased blood levels of TNF-α, IL-6, and IL-1β
Artemisia annua	Casticin and chrysosplenol D compound decrease IL-1β, IL-6, and MCP-1
Piper betle	4-Allyl-1,2-diacetoxybenzene exhibited stronger interactions with MMP-1, TGF, and IL-1 Allylpyrocatechol (APC) and methotrexate (MTX) inhibit the production of pro-inflammatory cytokines, such as TNF-α and IL-6.

However, this therapy has several disadvantages related to gastrointestinal, cardiovascular, and nephrotoxic effects. Therefore, alternative medicine, such as the consumption of herbal medicine, is highly beneficial for complementary therapy. However, more information is required about plants or compounds that potentially be used to treat rheumatic disorders. In this book chapter, we identified 33 plants containing more than 15 compounds for anti-rheumatoid arthritis activity, osteoarthritis, gout, etc. The articles mentioned in the chapter book apply several study designs, including in silico, in vitro, and in vivo techniques. The findings of this review indicate that these plants have an effective mechanism for inhibiting multiple protein targets in rheumatic disorders, including TNF-α, interleukins, NO, iNOS, ROS, MMP, NF-kB, COX-1, COX-2, PGE2, MCSF, and others. Regarding the activity of several plants and compounds on arthritis protein targets, however, additional research is still required so that plants with potential anti-arthritis disorder activity can be identified.

Contents

Abstract

The fact that botanical compounds have been extensively used to cure various diseases and ailments throughout history is well known. Several of these compounds have been reported to be powerful antioxidants, anti-inflammatory agents, and antiapoptotic agents. Furthermore, these mechanisms have also been involved in ocular diseases, such as age-related macular degeneration (AMD), glaucoma, diabetic retinopathy, cataracts, and retinitis pigmentosa. Recent studies have demonstrated that several epidemiological and clinical studies have been performed that have shown the benefit of plant-derived compounds on these ocular pathologies, such as curcumin, lutein, zeaxanthin, ginseng, and many others in recent years. Cell cultures and animal models have shown promising results when these drugs have been used to treat eye diseases in the laboratory. It is important to note that although there appear to be many significant correlations between these botanical compounds, further investigation is necessary to determine their mechanistic pathways. This will facilitate widespread pharmaceutical application and the development of non-invasive alternatives for significant eye diseases to provide non-invasive solutions to those diseases.

Keywords

Eye · Glaucoma · Cataracts · Diabetic retinopathy · Macular degeneration · Lutein

Abbreviations

AMD	Age-related macular degeneration
AMPK	AMP-activated protein kinase
AREDS	Age-related eye disease study
CB1	Cannabinoid receptor type 1
CBD	Cannabidiol
CGRP	Calcitonin gene-related peptide
COX-2	Cyclooxygenase-2
DR	Diabetic retinopathy
EGCG	Epigallocatechin gallate
fERG	Flash electroretinogram
GBE	*Ginkgo biloba* extract
GO	Graves' ophthalmopathy
HSP72	Heat shock proteins
HSV	Herpes simplex virus
HUVECs	Human umbilical vein endothelial cells
IGF-I	Insulin growth factor-1
IOP	Intraocular pressure
JNK	c-Jun N-terminal kinase
KRG	Korean red ginseng
LDLs	Low-density lipoproteins
LIRD	Light-induced retinal degeneration
MCP	Monocyte chemoattractant protein
MDA	Malondialdehyde
NF-kappa B	Nuclear factor kappa B
NO	Nitric oxide
NOS	Nitric oxide synthase
NTG	Normal tension glaucoma
PACAP	Pituitary adenylate cyclase-activating peptide
PCG-1alpha	Peroxisome proliferator-activated receptor gamma coactivator 1alpha
POAG	Primary open-angle glaucoma
Rb1	Retinoblastoma protein 1
RCTs	Randomized controlled trials
Rg3	Retinoblastoma protein 3
RGC-5	Retinal ganglion cell
ROS	Reactive oxygen species
RP	Retinitis pigmentosa
RPE	Retinal pigment epithelium

THC	Delta-9-tetrahydrocannabinol
TNF-alpha	Tumor necrosis factor-alpha
UV	Ultraviolet
VF	Visual field
WHO	World Health Organization

1 Introduction

The World Health Organization (WHO) estimates that approximately 34 million blind people live worldwide [10]. The eye has several natural defense mechanisms that it can use to protect itself from injury or infection. Tears, for instance, maintain a moist environment around the eye and physically remove any foreign particles, such as dust or microorganisms, that may have settled there. They also keep the eye from drying out. Moreover, tears have been found to contain several anti-infective substances, such as lysozymes and interferon. The eyelashes and eyelids keep the eye's surface moist while serving as a barrier between the ocular surface and the outside world. On the other hand, these protective mechanisms can become compromised occasionally, leading to eye inflammation. Eye infections are frequently and commonly reported in the South African province known as the Eastern Cape. These infections are brought on by exposure to bacteria, fungi, viruses, and other types of microorganisms. Traditional healers and herbalists recommend plant-based remedies for treating conditions like these [34, 56]. According to the various ancient and modern Chinese pharmacopoeia, numerous herbal treatments have been utilized for a significant amount of time to treat different eye conditions. They effectively treat night blindness, cataracts, floaters, and glaucoma, among other eye conditions. The usefulness of these treatments is deduced from anecdotal evidence and specific clinical results rather than going through the rigorous process of modern systematic scientific research, which would involve testing on animals and participating in clinical trials. In addition, the efficacies have a reputation for having a large amount of variation due to herbal remedies needing to be standardized in terms of their sources, qualities, combinations, or preparation methods [59, 60, 62, 63, 65, 66]. This is because these aspects of herbal remedies can affect their effectiveness. Despite this, the historical treatments documented for a long time are a goldmine for discovering natural products. Herbal extracts and herbal molecules that have been defined offer a superior alternative for the continued research and development of herbal medicines, making it possible to circumvent the challenges posed by variations. Because it has such a high metabolic rate, the eye is constantly damaged by the light's photooxidation. Damage caused by oxidative agents can quickly occur in the tissue cells of the eye. Even though there are several pathological factors associated with ocular diseases, such as age, inflammation, oxidative stress, genetic predisposition, tumorigenesis, diabetes, angiogenesis, and ischemia, it appears that oxidative stress plays a pivotal role in the pathogenesis of ocular diseases. Any of these contributors can cause ocular diseases, but they all work together.

The Aim and Objective of the Chapter

- To analyze the effectiveness of herbal medicines in managing glaucoma symptoms and preventing progression.
- To investigate the potential of herbal remedies in reducing intraocular pressure for glaucoma patients.
- To assess the impact of herbal treatments on retinal health in diabetic retinopathy cases.
- To examine the role of herbal supplements in preventing cataract formation and progression.
- To explore the antioxidant properties of herbal extracts for protecting against age-related macular degeneration.
- To evaluate the safety and efficacy of herbal therapies in alleviating dry eye symptoms.
- To investigate the mechanisms by which herbal medicines can improve visual function in eye diseases.
- To identify potential herbal interventions for reducing ocular inflammation in various eye conditions.
- To examine the impact of herbal supplements on improving ocular blood flow in glaucoma.
- To assess the clinical outcomes of using herbal treatments in conjunction with conventional therapies for eye diseases.
- To determine the neuroprotective effects of specific herbal compounds in glaucoma management.
- To analyze the anti-inflammatory properties of herbal medicines for reducing eye discomfort and redness.
- To investigate the role of herbal remedies in preventing or delaying the onset of cataracts.
- To explore the potential of herbal therapies in addressing oxidative stress in diabetic retinopathy.
- To evaluate the safety and tolerability of herbal supplements as adjunct treatments in ophthalmology.
- To examine the impact of herbal interventions on improving contrast sensitivity in eye diseases.
- To assess the effectiveness of herbal treatments in preventing vision loss associated with age-related eye conditions.
- To investigate the mechanisms of action of herbal compounds in preserving retinal health.
- To explore the synergistic effects of combining herbal and traditional glaucoma medications.

Several different risk factors have been associated with age-related macular degeneration, also known as AMD, including getting older, smoking cigarettes, being exposed to sunlight, and consuming a diet that is high in fat and low in antioxidants, in addition to having specific genetic variants (such as the polymorphism of complement factor H), has been shown to increase the risk of developing cardiovascular disease. There is a correlation between these potential dangers and oxidative pressure, ultimately damaging retinal tissue. This includes damage to retinal pigment epithelium, photoreceptor cells, and choroidal capillaries. Glaucoma causes progressive and irreversible death of retinal ganglion cells, damage to the optic nerve and loss of vision, even without increased intraocular pressure. This is because glaucoma causes pressure to build up inside the eye. Oxidative stress is responsible for cytotoxic effects, a degeneration of the retinal ganglion cells, and damage to the trabecular meshwork, all of which contribute to an obstruction of the flow of an increase in intraocular pressure as well as the production of aqueous humor [44, 58, 68, 69]. The gradual clouding of the lens that occurs because of prolonged exposure to light is the underlying cause of cataracts. This photooxidation is responsible for the breakdown of biological components of the lens, most notably crystallin. Molecules that possess crystalline structures and contain oxidized thiol groups tend to establish disulfide bonds, resulting in the agglomeration of crystals and the consequent onset of cataract formation. Oxidative stress is increased due to diabetes, which leads to damage to capillary cells and the microvasculature of the retina. An impairment in glyceraldehyde-3-phosphate dehydrogenase is another factor that contributes to the pathogenesis of diabetic retinopathy brought on by diabetes. This factor incorrectly activates significant biochemical pathways [46]. The medical condition known as Graves ophthalmopathy, or GO, is characterized by an abnormal eyeball bulging and is partially brought on by hyperthyroidism. It affects anywhere between 25% and 50% of Graves' patients. Roughly 5% of patients being treated have a condition that could harm their vision. Numerous pieces of evidence indicate that the pathogenesis of GO may involve oxidative stress [2]. The acceleration of essential metabolic processes and cellular oxidative metabolism in mitochondria results from excessive thyroid hormone production, resulting in an elevation in the generation of reactive oxygen species (ROS). The presence of an oxidative environment has the potential to induce cellular proliferation in fibroblasts located within the eye, which can lead to eye protrusion. Some research showed that active GO patients had higher levels of 8-hydroxy-20-deoxyguanosine (8-OHdG) in their urine and that GO orbital fibroblasts had higher levels of 8-OHdG, superoxide anions, malondialdehyde (MDA), and hydrogen peroxides. Among the elderly population, blindness ranks as the second most significant fear, following death. Common causes of blindness include ocular diseases like glaucoma, cataracts, and age-related macular degeneration (AMD). The development of cataracts is a significant challenge faced by the elderly population and has a considerable bearing on the cost of medical care. The lens is the component of the eye that is particularly vulnerable to oxidative damage. Cataracts are caused by the exposure of underlying epithelial cells to both exogenous and endogenous reactive oxygen species, in addition to cellular death and degeneration. The phenomenon above results in the cross-linking and aggregation of the crystallin proteins present in the lens, leading to the development of cataracts. The formation of cataracts is one of the age-related processes that is significantly impacted by oxidative stress. Because the type of cataract and its pigmentation are determined by the intensity and form of oxidative stress, this factor makes preventing cataracts more difficult. Dry eye syndrome is a prevalent ocular condition. It can cause eye pain, vision problems, and possible corneal surface damage. The fact that more and more people are going to ophthalmology clinics with symptoms of dry eye syndrome shows how important etiology is. It also shows how important it is to find out what causes dry eyes and stop doing those things. Surgeons should identify and assess preoperative risk factors while taking measures to prevent factors that may exacerbate this condition. Given its established status as a recognized syndrome in periorbital surgery, it is imperative to avoid this condition. The patient will be able to have a more straightforward recovery process if all potential risk factors associated with dry eye syndrome have been identified and considered. This will reduce the likelihood of the patient developing this complication. In 2007, according to the International Dry Eye Work Shop, dry eye disease was a condition that impacted both the tear film and the ocular surface. Symptoms of dry eye disease include pain, blurred vision, unstable tear film, and eye surface damage. Symptoms include a foreign body sensation, burning, itching, blurred vision, pain, and photophobia; scleral injection; ocular discomfort; and blurred vision. Non-healing epithelial defects, corneal thinning, infections, corneal perforation, and permanent vision impairment are some visual complications that can result from all these symptoms.

2 Different Types of Eye Infections

Bacterial eye infections: Microorganisms such as *Haemophilus influenza*, *Staphylococcus aureus*, *Streptococcus pneumonia*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Bacillus cereus*, *Neisseria gonorrhoeae*, *Staphylococcus epidermidis*, *and Chlamydia trachomatis* are responsible for the eye infection [29]. The bacteria *Staphylococcus aureus* and *Staphylococcus epidermidis* are the most common causes of external eye infections. *C. trachomatis* is the pathogen that leads to trachoma. This condition is the primary contributor to ocular morbidity and is the foremost infectious etiology of blindness globally [83]. According to the World Health Organization's estimation, the global population of individuals affected by trachoma is approximately 146 million. Some symptoms associated with bacterial eye infections include irritation, burning, tearing, and typically a mucopurulent or purulent discharge. It is possible to wake up with your eyelids stuck together. This is especially common in the morning. Even though bacterial eye infections are typically considered self-limiting, if they are allowed to go untreated, they can progress into more severe conditions threatening the patient's vision.

Fungal eye infections: *Fusarium oxysporum*, *Aspergillus niger*, *Fusarium solani*, *Candida albicans*, *Aspergillus flavus*, and *Penicillium notatum* are some of the fungal species that can cause infections in the eye [27]. The treatment of these infections poses a significant challenge and has the potential to lead to blindness. Redness, blurred vision, and sensitivity to light are some of the symptoms. Amphotericin B and Natamycin are two antifungal agents that can be applied topically to the eye to treat fungal infections [11, 19].

Viral eye infections: Coxsackieviruses, Herpes simplex virus-1, and adenoviruses are the three most common culprits behind viral infections of the eye [40]. In developed countries, ocular infection caused by HSV-1 is the primary etiology of visual impairment. Herpes simplex type 1 accounts for more than 95% of ocular herpes infections. Currently, 51 human adenovirus serotypes are known, which can be broken down into 6 species (A–F). In particular, the eyes can become infected with species D. Eye infections caused by viruses are highly contagious and are passed on through direct contact, most commonly through the sharing of items that have been in connection with the eye secretions of an infected person. For instance, the virus can be passed on when someone who already has individuals come into contact with contaminated surfaces, such as door handles, after touching their eyes. Additionally, sharing objects in connection with an individual's eyes, such as towels or pillowcases, between two people can also facilitate transmission. Antiviral medications like acyclovir, famciclovir, and valacyclovir can shorten the infection's duration and lessen the severity of the symptoms. Glaucoma is a common form of ocular disease that affects people all over the world. The demise of retinal ganglion cells characterizes glaucoma, the formation of a hollow at the optic nerve head, and, typically, a rise in intraocular pressure (IOP). Although elevated, the etiology of ganglion cell degeneration and optic disc cupping has long been attributed to intraocular pressure (IOP). However, research on low-tension glaucoma has provided evidence that challenges this notion, indicating that IOP may not be a sufficient or necessary factor in developing the disease. The cause of this condition is still unknown. Other mechanisms involving the neurosensory retina have been proposed. Recent research has brought attention to the possible neurotoxic function of glutamate. It has indicated that apoptotic mechanisms could be implicated in the deterioration of ganglion cells [38]. Glaucomatous eyes of dogs, monkeys, and humans have been found to have abnormally high levels of glutamate in the vitreous. Many of its morphological features resemble those of human congenital glaucoma, including an expanded retinal surface, an atypical corneal endothelium exhibiting cellular degeneration, insufficiently differentiated cells with a collapsed trabecular meshwork, and an adhesion of the anterior aspect of the iris to the posterior cornea. It is believed that several stimuli can start or start the process of apoptosis in glaucoma. Therefore, elevated intraocular pressure (IOP) and the accumulation of organelles at the optic nerve head may be able to obstruct axoplasmic flow, thereby impeding the circulation of trophic factors [30]. Mitosis, conjunctival hyperemia, and the inflammatory response in the eye are comprised of the breakdown of the blood-aqueous barrier, resulting in the subsequent leakage of protein into the aqueous humor. The nature, duration, and strength of the noxious stimulus determine the extent of these reactions. Substance P and calcitonin gene-related peptide (CGRP) are two examples of C-fiber neurotransmitters that have been demonstrated to play an essential role in the ocular response to injury. Both neurotransmitters are involved in healing [26]. Recent research has identified pituitary adenylate cyclase-activating peptide (PACAP), a C-fiber neuropeptide that has been shown to play a role in ocular inflammation in rabbits. Any transmitter removed from local nerve fibers will diffuse into the anterior chamber because there is no barrier between the iris, the ciliary body, and the anterior chamber. This is because the anterior chamber is directly connected to the ciliary body. Because of this, research on the release of transmitters benefits significantly from using the eye as a model. Nitric oxide (NO) is a molecule with a short half-life that participates in various biological processes. Recent observations suggest that NO may significantly regulate ocular function in its physiological or pathophysiological aspects. Therefore, the presence of NOS activity in the anterior uvea of rabbits has been demonstrated. At the same time, NOS immunoreactivity has been observed by immunizing nerve fibers in the uvea of rat eyes. Both findings can be found in the literature. It was discovered that administering L-NAME to the rabbit via intravenous injection caused a reduction in the regional blood flow in the uvea. It is interesting to note that the activation of ocular C-fibers in response to a minor injury (infrared irradiation of the iris) appears to involve the participation of nitric oxide (NO).

Ocular injuries – Exposure to industrial chemicals like acid and alkali, radiation energy like ultraviolet light, and physical trauma all contribute to ocular injuries in the workplace. Although injuries to the eye caused by plant saps are uncommon, they can have serious consequences [42].

Conjunctivitis – Conjunctivitis is a medical condition characterized by mucous membrane inflammation that lines the eyelid's inner surface. Various things can cause conjunctivitis, such as viruses, bacteria, allergies, injuries, or other foreign substances. The following are some symptoms: itchiness, watery eyes, bloodshot eyes, pain, and occasionally blurred vision. Depending on what caused conjunctivitis in the first place, there are a few different treatments available. In most cases, antibiotics are prescribed for the treatment of bacterial infections. Eyewashes can also be made from several herbal combinations [9].

3 Major Eye Diseases Share Common Mechanistic Pathways

The most common causes of blindness can be broken down into four categories: age-related macular degeneration (AMD), cataracts, glaucoma, and other retinal diseases such as retinitis pigmentosa (RP) and diabetic retinopathy (DR) [74]. According to the findings of an epidemiologic study that the Eye Diseases Prevalence Research Group carried out, it is estimated that by the year 2020, there will be 30.1 million people in the United States with cataracts. Furthermore, it was estimated that 4.1 million individuals aged 40 and above in the United States would have diabetic retinopathy [15]. Approximately 2.95 million individuals in the United States would receive a diagnosis of age-related macular degeneration (AMD), and about 2.2 million individuals would receive a diagnosis of glaucoma. It is interesting to note that all these diseases are linked to aging and that the mechanisms that underlie their respective etiologies and pathophysiologies are similar in several respects. The pathways above encompass apoptotic factors, inflammation, and oxidative stress, offering valuable insights into areas that may be amenable to targeted interventions. Oxidative stress is induced by reactive oxygen or nitrogen species, and lipid peroxidation is responsible for the death of ocular cells in many eye diseases. Various pathological pathways are associated with inflammatory factors, including nuclear factor kappa B (NF-kappa B) and tumor necrosis factor-alpha (TNF-alpha). It is interesting to note that the mechanisms of these pathways often intersect with those of numerous botanical compounds. Oxidative stress causes the generation of reactive oxygen species, leading to their interaction with mitochondria, subsequently triggering the activation of the JNK pathway, ultimately resulting in the cell's death. This review will concentrate on AMD, DR, RP, and glaucoma as pathologies and the possible benefits of botanical compounds in preventing and treating these eye diseases. This is because all these conditions have a significant impact on populations all over the world.

Age-related macular degeneration (AMD): Age-related macular degeneration is a persistent retinal condition commonly observed in individuals aged 50 years or above. The degeneration of photoreceptor and RPE cells in the macula results in a loss of central vision, both of which are necessary to provide sharp and clear vision. Smoking, one's racial or ethnic background, and one's family medical history are various factors that have been identified as potential contributors to the development of age-related macular degeneration, a prevalent cause of blindness among elderly individuals on a global scale, according to numerous epidemiologic studies. Oxidative stress and inflammation are essential mechanistic pathways to the pathology [31]. As per the results of the National Eye Institute's Age-Related Eye Disease Study (AREDS), the consumption of dietary supplements that comprise antioxidants and zinc has the potential to diminish the likelihood of advanced AMD onset and consequent vision impairment to a considerable extent [4]. This research opens the door for discovering potentially beneficial natural compounds for managing and prophylaxis of age-related macular degeneration (AMD). The investigation of the active ingredients of various plants has revealed their potential as antioxidants and anti-inflammatory agents. These characteristics are crucial in managing and avoiding age-related macular degeneration (AMD) and other ocular ailments which have already been present.

Glaucoma: Glaucoma is a term that refers to a set of ocular disorders that may interrupt the transmission of visual stimuli from the eye to the brain [3]. Most glaucoma cases are attributed to optic nerve damage resulting from the apoptosis of retinal ganglion cells [78]. The medical term for the heightened force within the eye is intraocular pressure (IOP), frequently used in clinical settings. Glaucoma patients typically have their intraocular pressure (IOP) lowered using oral medications, eye drops, or surgery [47]. This is the primary treatment method for the disease. Even though the elevation of intraocular pressure (IOP) is considered a leading etiological factor in the development of glaucoma, many cases continue to worsen even after the eye pressure has been brought down to the normal range. Developing novel and creative approaches to damage prevention and mitigation and reducing intraocular pressure is essential in such situations. The role of apoptosis in the pathogenesis of glaucoma has been well established. Therefore, investigations into the efficacy of neuroprotective agents may yield promising results. Various chemical components are found in plants that exhibit neuroprotective qualities and have the potential to be helpful in the treatment and prevention of glaucoma.

4 Diabetic Retinopathy (DR) and Retinitis Pigmentosa (RP)

Individuals diagnosed with either type 1 or type 2 diabetes are susceptible to the development of diabetic retinopathy. Diabetic retinopathy (DR) is considered one of the primary causes of blindness worldwide, in addition to age-related macular degeneration and glaucoma. It is estimated that DR affects 140 million people [85]. Changes in the retinal blood vessels bring on the pathology in this case. There is a possibility that blood vessels will swell or leak, and the emergence of anomalous blood vessels on the retina's surface is a possibility. Four stages comprise the DR pathology: severe no proliferative retinopathy, moderate no proliferative retinopathy, mild no proliferative retinopathy, and proliferative retinopathy. Proliferative retinopathy is the final stage. No treatments are necessary for the first three stages of the disease; even so, patients in these phases are required to regulate their blood cholesterol, blood pressure, and blood sugar [21]. This is done to prevent the disease from progressing further in these stages. Laser surgery is required to stem fluid flow out of the eye when proliferative retinopathy is present. However, in severe bleeding, a vitrectomy may be necessary to remove blood from the macula (the central part of the retina) [85]. The laser treatment may help reduce the size of the abnormal blood vessels, but a vitrectomy is necessary in these circumstances. Another disease that affects the retina is called retinitis pigmentosa, or RP for short. This condition causes rod and cone cells in the retina to become damaged, resulting in impaired vision and, in severe cases, total blindness. Retinitis pigmentosa is a rare disease affecting only 1 in 4000 people in the United States [75]. Genetic predisposition is the primary factor that puts a person at risk for developing this condition. Because there are currently no treatments available for retinitis pigmentosa, the state is a significant source of concern, even though it is not as common as other eye diseases. However, results from earlier experiments conducted on mice suggested that high doses of antioxidants, such as vitamin A palmitate, may slow the progression of the disease. Numerous plant extracts have the potential to have significant effects on the treatment as well as the prevention of both RP and DR. However, because no studies have been conducted in a clinical setting, there are plenty of questions regarding the potential advantages of taking such supplements.

Cataract: A cataract is an eye disease that commonly affects older people and typically begins to manifest in people's eyes around the age of 60. The lens becomes cloudy due to this pathology because of the breakdown of proteins, which causes the lens to be affected. Damage to the lens causes vision to become blurry, as well as a reduction in the sensitivity to colors and shapes; the lens is an essential component for achieving focus on objects situated at varying distances, whether they are nearby or distant. It is known that several risk factors, including smoking, exposure to ultraviolet (UV) light, diabetes, eye injury, and family history, can increase the likelihood of developing cataracts [91]. Patients who suffer from cataracts can easily be cured by undergoing surgery. The cloudy lens causing the condition will be surgically removed during the procedure, and an intraocular lens will be inserted. It is estimated that cataracts cause 51% of the world's blindness. However, surgery can restore sight in most patients who undergo it; several nations lack access to sophisticated eye care services. Fortunately, new research suggests that limiting protein degradation in the eye by eating botanical compounds rich in antioxidants may help reduce the risk of cataracts.

5 Therapeutic and Adverse Effects of Herbal Remedies

5.1 Ginkgo *(Ginkgo biloba)*

GBE, an extract derived from the *Ginkgo biloba* plant, has been extensively documented in various sources and is made by processing the leaves of a tree estimated to have originated in China more than 250 million years ago. For centuries, *Ginkgo biloba* extract has been utilized in traditional Chinese medicine and is thought to help improve cognitive function. It is widely available in supplement form and is popular among people looking to improve their memory and focus. As we all know, *Ginkgo biloba* extract (GBE) is predominantly comprised of flavonoids and terpenoids, with a total of more than 60 distinct bioactive compounds, of which 30 are exclusive to GBE and cannot be found anywhere else in nature [16]. GBE is a safe and effective natural supplement with a variety of applications. It has been employed to treat various medical conditions, including depression, memory loss, anxiety, and fatigue. Research suggests that GBE can also help improve mental clarity and focus. In addition, it is an herbal supplement most frequently used by individuals who have reached the age of 65 or above [13]. GBE exhibits a high degree of tolerability and presents a limited incidence of adverse effects. Therefore, it can be safely used as a supplement for elderly patients looking for natural remedies for their health issues. It has been found that the pathogenesis of glaucomatous optic nerve degeneration remains largely unknown. However, evidence suggests that neuroinflammation, oxidative stress, and optic nerve ischemia may be involved in its development. GBE can act as an antioxidant and reduce these oxidative stress levels, thus potentially slowing down the progression of glaucoma. It also has anti-inflammatory properties, which can help reduce the inflammation in the optic nerve and improve patients' vision. According to research, gamma-butyrobetaine, or GBE, is a potent antioxidant that can protect tissues against damage caused by free radicals, just like other antioxidants, like vitamins C and E, do. These properties of GBE make it a promising option for treating glaucoma. GBE supplementation is safe and effective in early studies. Additional investigation is required to validate its effectiveness in the treatment of glaucoma. By contrast, GBE operates at the organelle level by providing molecular stabilization to the mitochondria. The fact that it has this property sets it apart from the other agents. During oxidative stress, it has been observed that alterations in mitochondrial function can render retinal ganglion cells more susceptible to the deleterious impact of oxidative stress [23, 49]. GBE has been found to increase the stability of the mitochondria and reduce the damage caused by oxidative stress, suggesting that it may be effective in treating glaucoma. Further research is needed to confirm its efficacy.

According to the findings of one study, the application of GBE has the potential to decrease the quantity of reactive oxygen species within cultured neuronal cells and protect the mitochondrial membrane. The vasodilatory properties of GBE have been discovered to have potential benefits for enhancing coronary and peripheral circulation. Additionally, GBE has been found to have rheological effects that could improve blood viscosity [33]. Both findings were made possible by the fact that GBE has vasodilatory properties. Additionally, GBE can lessen the number of active cells (such as glial cells) in low-grade inflammation [12]. GBE is regarded as a neuroprotective agent because of its antioxidant, vast regulatory, and anti-inflammatory properties. As a result, there has been a suggestion that it could serve as a viable treatment option for individuals with glaucoma. Researchers have conducted four randomized controlled trials (RCT) to investigate GBE's impact on glaucoma. The first study was a double-blind, placebo-controlled crossover experiment on patients with normal tension glaucoma (NTG) [73]. The participants were allocated randomly to either of the two intervention groups: 4 weeks of GBE administration followed by 8 weeks of placebo or the opposite. Even though GBE supplementation led to statistically better visual field (VF) indices compared to baseline, the observed VF indices did not exhibit sustained improvement after the washout period, and no statistically significant alterations in intraocular pressure (IOP) were noted. In contrast, [25], who conducted a similar cross-over study, the study did not observe any statistically significant variations in the visual field (VF) indices or intraocular pressure (IOP). The treatment order and duration were identical in both studies; however, the second study only included patients recently diagnosed with NTG and taking topical hypotensive agents. The fact that the first study was carried out on a population from Europe and the second study was carried out on a population from Asia both suggest that differences in patient populations' ethnicities might be another factor that contributed to the findings. Another randomized controlled trial has demonstrated that using GBE has been observed to elicit a favorable impact on blood circulation in individuals diagnosed with NTG. This proposition implies that GBE can potentially serve as a therapeutic intervention for NTG. Further research is needed to confirm the findings and assess the safety and efficacy of GBE as a treatment. Specifically, following 4 weeks of *Ginkgo biloba* extract (GBE) supplementation compared to a placebo, there were notable enhancements in ocular blood volume, blood flow, and blood velocity due to GBE intake. The results of this study indicate that *Ginkgo biloba* extract (GBE) could serve as a viable therapeutic option for individuals with normal tension glaucoma (NTG). However, further clinical trials are needed to confirm these results. Further studies should also be conducted to understand the long-term impact of GBE supplementation on NTG patients. In addition 2016, Dewi Sari and colleagues conducted a study on individuals diagnosed with primary open-angle glaucoma (POAG). The study involved the administration of GBE to the participants, and the researchers observed noteworthy enhancements in various parameters, including VF indexes, superior and inferior retinal nerve fiber layer thickness, malondialdehyde (a plasma-derived oxidative stress marker), and glutathione peroxidase (an antioxidant enzyme). These improvements were observed after 6 months of GBE administration compared to the placebo group. The study concluded that GBE could be a potential treatment option for POAG. It is noteworthy to mention that there were no reported negative consequences associated with the administration of GBE. Nevertheless, it is unknown whether, statistically speaking, there was a significant disparity in the level of improvement observed between the treatment group and the baseline group. Additional investigation is required to validate the efficacy of *Ginkgo biloba* extract (GBE) as a therapeutic intervention for primary open-angle glaucoma (POAG). Different dosage levels and treatment durations should be investigated to determine the optimal treatment protocol. Clinical trials should be conducted on the safety and effectiveness of *Ginkgo biloba* extract (GBE) in managing primary open-angle glaucoma (POAG). There are numerous benefits associated with Ginkgo. Studies have demonstrated the potential of Ginkgo to enhance memory, mitigate the likelihood of developing dementia, and ameliorate circulation. The safety and tolerability of this substance are widely acknowledged among the general population. Furthermore, Ginkgo has few known side effects and is widely available. GBE is typically well-tolerated, although its adverse effects should be considered, which are the most severe related to the fact that GBE acts as an antithrombotic. This means, it can increase the risk of bleeding, especially in those taking other medications that thin the blood. Therefore, it is important to consult a physician before taking Ginkgo to ensure there are no potential interactions with any other medications. There have been several case reports in which ocular complications have been identified, such as retinal hemorrhage and hyphema. In contrast, systemic effects have been identified, like subdural hematoma and subarachnoid hemorrhage have been reported in other case reports. Ginkgo should not be taken without consulting a doctor, as it may have adverse effects. These can range from ocular complications to systemic effects like subarachnoid hemorrhage. Following the doctor's advice on dosage and usage when taking Ginkgo is important. Nevertheless, it has been found that the incidence of bleeding is not significantly different between patients who take GBE and those who take a placebo (based on the results of the two randomized controlled trials (RCTs) that examined the effect of GBE on elderly patients [17].

Bilberry *(Vaccinium myrtillus)*: Since the sixteenth century, people have used bilberry fruit for its medicinal properties. About half of the glaucoma patients who responded to a survey about using herbal remedies for treatment said they took bilberry [77]. Anthocyanin, a type of flavonoid, is the bilberry component responsible for its medicinal properties [76]. Like GBE, bilberry's proposed therapeutic effect is based on the evidence that a neurodegenerative process characterizes glaucoma, and this substance has the potential to act as a neuroprotective agent and combat that process. This statement pertains to the augmentation of retinal ganglion cell density, the fortification of optic nerve architecture, the amelioration of retinal ganglion cell resilience against mechanical or ischemic perturbations, and the mitigation of neuroinflammatory processes. Several proposed mechanisms of action exist for bilberry, including 1) antioxidative properties, 2) decreased capillary fragility, 3) collagen stabilization and promotion of collagen production, and 4) prevention of the production and release of proinflammatory compounds. Research into the use of bilberry as a treatment for glaucoma has been conducted due to the positive effects that bilberry has on antioxidation and blood circulation. This study is a retrospective investigation examining the controlled impact of bilberry supplementation and GBE for 6 to 59 months. It found that those who took the supplements improved their visual acuity, while those in the control group saw a decline in their visual acuity [80]. Additionally, VF improved, but the statistical analysis revealed no significant differences in VF between the treatment and control groups. There was no discernible impact on IOP from the use of bilberry supplements. A randomized controlled trial lasted 24 months, and individuals who were administered anthocyanin supplements exhibited a decrease in VF mean deviation. Nevertheless, the reduction in mean deviation was notably inferior in the group receiving treatment compared to the group receiving placebo. In the studies discussed above, the use of bilberry was not associated with any adverse effects. Conversely, an overdose of bilberry can result in symptoms such as icterus, anemia, and cachexia.

Marijuana *(Cannabis sativa)*: Marijuana, also referred to as cannabis, has a long history of use for therapeutic purposes dating back thousands of years; however, its acceptance in Western medicine has a tumultuous past [1]. In 1937, the United States passed a law that made marijuana use illegal. The use of marijuana for medicinal purposes was made legal in California in 1996, making it the first state to do so. Since then, a cumulative count of 32 states and the District of Columbia have enacted legislation similar to California's, legalizing the medicinal use of marijuana. The increasing legalization of marijuana and a shift in social attitudes toward its use have led to a greater likelihood of glaucoma patients utilizing marijuana as a therapeutic alternative. Cannabidiol (CBD) and delta-9-tetrahydrocannabinol (THC) are the chemical compounds responsible for marijuana's physiological effects. Marijuana is made up of over 400 different compounds (CBD). There is a lack of knowledge regarding the mechanism of action responsible for the ocular effect that marijuana produces. The endocannabinoid system relies on the crucial G-protein receptors, cannabinoid receptor type 1 (CB1) and cannabinoid receptor type 2 (CB2). The CB1 receptor is situated in the ciliary body, muscles, trabecular meshwork, and Schlemm's canal, indicating its potential influence on the production of aqueous humor and the outflow of trabecular and uveoscleral fluids. On the other hand, the CB2 receptor is known to regulate cytokine release in the immune system [6]. It is hypothesized that marijuana possesses a neuroprotective property, among other mechanisms, reducing free radicals and inhibiting apoptosis. The effects of marijuana smoking on a limited number of healthy participants were investigated by Hepler and Frank, revealing a reduction of 30% in intraocular pressure (IOP). On the other hand, only about 65% of people would feel this [24]. The pressure-lowering effect lasts for only a short time – between 3 and 4 hours on average. THC can be administered through various routes, including inhalation, oral ingestion, sublingual administration, intravenous injection, and topical application. The topical application of cannabinoid extracts is not an optimal route of administration for treating glaucoma due to the low aqueous solubility and highly lipophilic nature of these extracts, which result in poor ocular penetration. This is contrary to what one might assume to be the case. The study conducted did not reveal any noticeable variation in the intraocular pressure (IOP) among the subjects who were administered with topical 1% THC or light mineral oil (control) within a short duration [36]. However, WIN55212-2, a more recently developed topical synthetic cannabinoid, lowers intraocular pressure (IOP) by 20–30% in glaucoma patients, but the maximal effect takes place after an hour [72]. The study demonstrated that synthetic cannabinoids, namely, BW29Y and BW146Y, when orally administered to patients with glaucoma, reduced intraocular pressure (IOP). The findings indicated that BW146Y was equally effective in reducing IOP compared to the consumption of THC through smoking marijuana. However, BW29Y did not exhibit any significant impact on IOP. Notably, CBD increased intraocular pressure (IOP) in mouse eyes at intervals of 1 and 4 hours following topical administration, in contrast to THC [48]. In a study conducted on humans, analogous outcomes about elevated intraocular pressure (IOP) were noted after the sublingual administration of greater cannabidiol (CBD) after a lapse of 4 hours. Marijuana use has been associated with various negative outcomes, including psychotropic effects such as cognitive impairment, euphoria, dysphoria, decreased coordination, decreased short-term memory, time distortion, and sleepiness. Cardiovascular effects such as tachycardia, hypotension, conjunctival hyperemia, and decreased lacrimation have also been linked to the use of this substance. Moreover, the potential hypotensive impact of marijuana on intraocular pressure (IOP) may be counteracted by the concomitant reduction in blood pressure, resulting in inadequate blood supply to the optic nerve and consequent ischemic alteration [50]. If you smoke marijuana, you risk developing emphysema and possibly lung cancer. Topical THC can cause corneal injury and local irritation in some people. These are some of the side effects specific to the route of administration. There is a need for additional concern regarding the possible addictive properties and the level of tolerance. This is a particularly concerning finding because for patients to attain round-the-clock intraocular pressure (IOP) regulation through marijuana consumption, they must engage in smoking activities approximately six to eight times within 24 hours. However, this frequency of use is likely to lead to the development of cannabinoid use disorder. The monthly cost is anticipated to be approximately $690 to keep this dose, a sizeable increase from the currently prescribed medications.

Curcumin: Curcumin, also called *Curcuma longa*, commonly known as turmeric, is a widely utilized spice in South Asian cuisine. Curcumin is a naturally occurring compound obtained from the *Curcuma longa* plant. It has been extensively used for its anti-inflammatory properties in managing various inflammatory disorders [23]. Curcumin is a polyphenol with lipophilic properties, rendering it insoluble in aqueous solutions; however, it can maintain its integrity in environments with an acidic pH, such as the human stomach [49]. Interaction with various molecular targets for inflammation is required for curcumin's anti-inflammatory effects. For instance, this is achieved through the regulation of enzymatic activity, including but not limited to nitric oxide synthase (iNOS), cyclooxygenase-2 (COX-2), and lipoxygenase. This is how it works to regulate the inflammatory response. Inflammatory cytokines such as monocyte chemoattractant protein (MCP), TNF, interleukins, and migration inhibitory protein are all produced in lower quantities when curcumin is present [18]. This study investigates the impact of curcumin, an anti-inflammatory and antioxidative agent, on light-induced retinal degeneration (LIRD) in rat models and retina-derived cell lines. Studies have demonstrated the anti-inflammatory and antioxidative properties of curcumin. Retinal neuroprotection was noted in rats supplemented with 0.2% curcumin for 2 weeks. Through the inhibition of NF-kB activation and the downregulation of inflammatory gene expression, curcumin protected the retina from the effects of LIRD. When used in experiments as a pretreatment for the utilization of retina-derived cell lines, namely, 661W and ARPE-19, curcumin has been observed to confer cellular protection against hydrogen peroxide (H_2O_2)-induced cell death. This protective effect is attributed to activating cellular protective enzymes, including HO-1 and thioredoxin [33]. These results were found in studies. The study revealed that the cytoprotective properties of curcumin against oxidative stress induced by H_2O_2 were augmented when human retinal cells were incubated with 15 M curcumin. This effect was attributed to the upregulation of HO-1 expression, which decreased reactive oxygen species (ROS) levels [12]. Curcumin can also change the expression of NF-B, AKT, NRF2, and growth factors, which stop inflammation and protect cells. Studies with real-life rat models have demonstrated that curcumin directly impacts ocular disorders. Curcumin has been shown to have protective effects. The present study investigates the impact of oral administration on Wistar albino rats with streptozotocin-induced diabetic retinopathy in recent DR studies. Studies have demonstrated the potential of curcumin to inhibit the development of cataracts in rat models induced by selenite ingestion, galactose ingestion, naphthalene exposure, and diabetes [25]. The inclusion of curcumin in the dietary regimen of diabetic rats was found to confer protection to their lens against cataractogenesis. This was attributed to preserving the chaperone-like function of lens-crystallin [14]. Curcumin has been linked to several unwanted side effects since it was first studied in 1976, even though it has shown some promise as a possible natural treatment. Alterations to chromosomes and DNA are the primary types that can occur at higher doses of curcumin. Curcumin has been identified as the preferred compound for managing and prophylaxis of age-related macular degeneration (AMD), cataracts, and diabetic retinopathy (DR). However, it is noteworthy that curcumin possesses antioxidative and anti-inflammatory properties that may result in adverse effects at elevated dosages.

Lutein and zeaxanthin: Understanding that macular pigments comprise carotenoids such as lutein and zeaxanthin is important. They are found in the macula, the part of the retina responsible for the sharpest central vision, and are essential for healthy vision. Lutein and zeaxanthin are believed to act as “sunglasses for the macula,” protecting it from the negative effects of blue light. Generally speaking, these carotenoid pigments are found in higher concentrations in the macula and retina of humans. Carotenoids are present in various fruits and vegetables, including but not limited to kale, spinach, and maize. They are frequently consumed in the form of dietary supplements. Research has suggested that augmenting the consumption of lutein and zeaxanthin can potentially mitigate the likelihood of age-related macular degeneration. In addition, they can be found in a wide variety of fruits and vegetables, including red grapes, kale, spinach, corn, kiwi, and kiwifruit [37]. Lutein and zeaxanthin are also found in egg yolks, oranges, and mangoes. They may also have a protective effect on the eyes from UV light. In addition, carotenoids have the potential to exhibit anti-inflammatory and antioxidative characteristics. Multiple epidemiological studies have demonstrated an association between decreased likelihood of age-related macular degeneration and elevated levels of lutein and zeaxanthin in the bloodstream. Notably, this relationship has been observed in studies such as the Age-Related Eye Disease Study (AREDS) and the Case-Control Study Group for Eye Diseases in the United States. This suggests that consuming foods rich in lutein and zeaxanthin may help reduce the risk of AMD [52–54, 55, 57]. Furthermore, supplementation with lutein and zeaxanthin has also reduced the risk of AMD. There is still some debate about the exact mechanism by which lutein and zeaxanthin work, but it has been hypothesized that carotenoids have the potential to safeguard the macula and outer retinal segments of photoreceptors against oxidative stress through the activation of an antioxidant cascade, which subsequently deactivates reactive oxygen species [24]. Furthermore, it has been proposed that lutein and zeaxanthin play a significant role in the metabolic processes of photoreceptor cells, thereby contributing to the preservation of optimal visual health. Research has indicated that lutein and zeaxanthin possess the potential to safeguard the macula against harm caused by blue light. For this hypothesis to be accepted, it is necessary to consider that lutein and zeaxanthin possess antioxidant properties. These antioxidants help to scavenge free radicals and protect the macula from oxidative damage. Thus, lutein and zeaxanthin play a vital role in maintaining healthy vision. In addition, lutein and zeaxanthin also perform the function of light filters within the eye, absorbing blue light before it reaches the retina, thereby protecting the retina from damage. Lutein and zeaxanthin can be found in many fruits, vegetables, and supplements, making them easy to obtain. A balanced diet with these nutrients is essential for maintaining healthy vision. As a result, the retina is protected from the harmful effects of LIRD, which can be caused by acute light exposure and exposure to highlight levels. The consumption of lutein and zeaxanthin has been associated with a potential decrease in the likelihood of developing age-related macular degeneration and cataracts. Taking these nutrients regularly can help improve vision and eye health. A study on cultured ARPE-19 cells indicates that providing lutein and zeaxanthin led to decreased photooxidative damage and suppressed gene expression linked to inflammation in RPE cells. The results of this study indicate that lutein and zeaxanthin can safeguard the eyes against oxidative stress and inflammation commonly linked to the deterioration of vision due to aging. This can significantly improve individuals' eye health and vision as they age. Furthermore, several epidemiological studies have revealed an inverse correlation between the amount of macular pigment and the likelihood of age-related macular degeneration (AMD) among older individuals. Therefore, augmenting the dietary consumption of lutein and zeaxanthin can potentially mitigate the likelihood of acquiring age-related macular degeneration (AMD). Supplementation with these two carotenoids has also been beneficial for reducing the risk of AMD. As per a recent clinical study that was published in an American Academy of Ophthalmology journal, the administration of lutein and zeaxanthin supplements exhibited an improvement in visual function and deceleration in the advancement of AMD pathology among patients diagnosed with early AMD [48]. Additionally, the research above revealed a positive correlation between the intake of lutein and zeaxanthin supplements and increased macular pigment optical density. This suggests that the intake of lutein and zeaxanthin supplements has been suggested to potentially mitigate the likelihood of age-related macular degeneration (AMD) by augmenting the optical density of the macular pigment. Zeaxanthin has also been shown to enhance the visual function of older male patients with AMD in clinical studies that were similar to this one. This indicates that lutein and zeaxanthin supplementation may have a protective effect against AMD and may also help improve the visual function of people already suffering from AMD. The consumption of lutein and zeaxanthin supplements may be a useful choice for preventing macular degeneration in the future [50]. Additional research is required to ascertain the precise dosage and duration necessary to elicit the protective effects of lutein and zeaxanthin supplementation. It is also important to consider the potential side effects of supplementing these carotenoids. Finally, diet is a key factor in determining an individual's risk for AMD and should also be considered.

Saffron: Because of its ability to reduce toxicity, saffron is one of the spices frequently used in traditional medical practices since it reduces toxicity. Saffron is recognized for its antioxidative and anti-inflammatory characteristics. It has been employed to treat diverse medical conditions, from dermatological disorders to gastrointestinal ailments. Additionally, it is believed to have mood-boosting effects. To provide it with its antiapoptotic properties, crocin and crocetin are the active ingredients that are present in them. These two compounds work together to reduce oxidative stress, thus providing saffron with its health benefits. Studies have also suggested that saffron has been found to possess potential health benefits in reducing the incidence of specific types of cancer and cardiovascular disease. The antioxidant carotenoids crocin and crocetin are known to prevent the onset of apoptosis by protecting cells from the effects of reactive oxygen species. Saffron also has anti-inflammatory effects, and consumption of certain foods may have a beneficial effect on reducing inflammation and promoting overall health. Additionally, saffron can help to reduce the risk of depression and improve cognitive function, concentration, and memory. There is evidence that crocin inhibits apoptosis in serum-starved PC12 cells exposed to hypoxic conditions, peroxidation of membrane lipids, and caspase-3 activation in serum-starved PC12 cells. Furthermore, research has indicated that saffron may have potential therapeutic benefits in addressing oxidative stress and inflammation in brain tissue, thereby indicating its potential utility in treating Alzheimer's disease. In addition, it also increases the levels of glutathione (GSH) in the body. It prevents the activation of the JNK pathway, which plays a crucial role in the downstream signaling cascade initiated by ceramide [45]. These findings suggest that saffron could be a potential therapy for Alzheimer's and other neurological diseases. Further research is needed to validate these findings and explore saffron's full potential as a therapeutic agent. It has been demonstrated that low GSH levels in the body lead to enhanced sensitivity of the cells to agents that induce apoptosis; dietary supplementation with saffron may potentially safeguard cells against damage and death by preserving glutathione (GSH) levels within the body

[51]. This suggests that saffron may exhibit a safeguarding impact against cellular damage and mortality caused by oxidative stress. Further research will be necessary to confirm these findings and to elucidate the exact mechanisms by which saffron exerts its protective effects. The addition of crocin to the RGC-5 retinal ganglion cell line inhibited oxidative stress in the cells, as shown by a decrease in the production of caspase-3 and -9, thereby preventing the death of the cells [84]. The findings of this investigation propose that saffron exhibits promising prospects in the prophylaxis and management of neurodegenerative ailments. Additional investigation is required to establish the effectiveness and safety of saffron for the aforementioned medical conditions. These findings were gleaned from research conducted on the RGC-5 cell line. Numerous studies have examined the potential impact of saffron as a dietary supplement, including clinical trials conducted on both human and rodent subjects. The effects of prolonged exposure to bright light were significantly mitigated in rats given saffron supplements. Falsini et al. [20] found that when saffron was supplemented at a dose of 20 milligrams per day for 90 days, the study observed notable enhancements in the macular photopic flash electroretinogram (FERG) parameters, specifically in terms of amplitude and modulation threshold [20]. This supports the idea that saffron may be effective as a natural remedy for treating eye diseases caused by prolonged exposure to strong light. Further research is needed better to understand the effects of saffron on eye health. The findings above were obtained through clinical trials on human subjects diagnosed with early age-related macular degeneration (AMD). The administration of saffron through oral supplementation resulted in a noteworthy enhancement in macular function. However, the precise mechanisms underlying the advantageous impacts of saffron on photoreceptors and bipolar cells remain unclear. Studies on rats have shown evidence of saffron's ability to inhibit cell death in situations where the rats were exposed to intense light. Based on the findings of these preclinical investigations, it can be inferred that saffron exhibits neuroprotective properties. These findings suggest the possibility of saffron as a prospective therapeutic intervention for addressing retinal degenerative pathologies. Additional investigation is required to comprehensively comprehend the impacts of saffron on ocular health and its prospective therapeutic applications. According to the findings of the clinical trials, adding saffron to one's diet may temporarily improve one's retinal function; age-related macular degeneration can manifest in its early stages. As part of the research, it has been demonstrated that the inhibitory effect of saffron on the proteolysis of water-soluble protein fractions within the lens can prevent the formation of selenite-induced cataracts in Wistar rats. This is attributed to saffron's antiapoptotic and antioxidative properties. Additional investigation is required to comprehend the precise mechanisms underlying the impact of saffron on ocular well-being and whether its benefits can be sustained in the long term. Additionally, it is imperative to consider all possible adverse effects of consuming saffron supplements. This is accomplished through the saffron's ability to prevent cell death. Even though the studies do not provide conclusive evidence for the potential neuroprotective properties of saffron in age-related macular degeneration (AMD) and its potential role in the prevention of cataracts, despite the need for further investigation, the data above exhibit potential

for the advancement of prophylactic and remedial applications of nutritional supplements in combatting the ailments above. Further research is needed to understand the exact mechanisms of saffron's neuroprotective effects and validate the efficacy of saffron as a therapeutic or prophylactic agent in treating the aforementioned ocular conditions.

Catechin – Catechin is a polyphenolic antioxidant frequently discovered in green tea [28]. Epigallocatechin gallate (EGCG), found in the most significant quantity in green tea, is a catechin that has powerful antioxidative effects. Researchers have shown in the past that previous research has demonstrated that the administration of EGCG in conjunction with sodium nitroprusside via intraocular injections resulted in a safeguarding impact on the retinal photoreceptors, which suggests that EGCG may have a beneficial effect on patient individuals who experience ocular ailments characterized by oxidative stress [86]. This protective effect was further confirmed in a recent study that found that EGCG improved the visual acuity of individuals diagnosed with age-related macular degeneration. Thus, EGCG is a promising therapeutic agent for ocular diseases. Catechins have a few different mechanisms of action, including mitigating glutamate-induced toxicity via lipid peroxidation and protein modification, eliminating reactive oxygen species, and the oxidative changes of low-density lipoproteins. The oral administration of EGCG has been shown to the findings of the study indicate that the administration of the substance in rat models may have a potential therapeutic effect in mitigating light-induced retinal neuronal degeneration, thereby potentially serving as a prophylactic measure against photoreceptor cell death [87]. Similarly, when catechin was given to Sprague-Dawley rats with cataracts caused by N-methyl-N-nitrosourea, the cataract-caused apoptosis in the lens epithelium was stopped. This may help treat or prevent cataracts in people. Additionally, RPE cell migration and adhesion can be inhibited by EGCG, which offers a potential preventative action against AMD. As a result, catechin is a compound that should be considered for treating and preventing diseases like AMD.

Ginseng – The Panax ginseng plant's root, commonly called ginseng in traditional Chinese medicine, has been widely utilized in this field for an extended period. It is believed to help boost energy levels and improve overall well-being. It is also thought to possess antioxidant and anti-inflammatory properties, which may help to protect the body from disease. There are several active components in ginseng, but the most important are ginsenosides. Ginsenosides are thought to be responsible for many of the purported health benefits of ginseng, as they appear to have antioxidant, anti-inflammatory, and immune-modulating effects. Empirical evidence suggests that these substances positively impact cognitive abilities and physical aptitude. Ginsenosides, a class of steroidal saponins, have demonstrated the ability to impede glutamate-induced neurotoxicity, lipid peroxidation, and calcium influx into cells. These effects may contribute to preventing apoptosis [78]. The ginsenoside saponins Rb1 and Rg3 have been found to inhibit apoptotic cascades in cells. There has been evidence that retinoblastoma protein 1 (Rb1) and retinoblastoma protein 3 (Rg3) inhibit NMDA glutamate receptor activity, thus suppressing tumor necrosis factor-alpha production and providing neuroprotective effects to cultured cortical cells, which have been shown to have a wide range of pharmacological effects [7], targeting a wide range of tissues. This suggests that Rb1 and Rg3 could be potential drug targets for neurodegenerative diseases. Further research on their effects on other tissues is warranted. The medicinal use of ginseng dates back several millennia. In recent years, studies have found that ginseng may benefit the brain, including improved cognition and memory. It is thought that ginseng may work by increasing levels of Rb1 and Rg3, which could provide new insights into how it may be used as a treatment. As a result of oral administration of Korean Red Ginseng (KRG) to patients with glaucoma during clinical trials, there have been significant increases in the amount of blood flowing to the retina in the temporal peripapillary areas of the eye. The potential outcome of this could be a decrease in the intraocular pressure and a postponement in the advancement of the ailment. Further research is needed to confirm the efficacy of KRG in treating glaucoma. To prevent glaucoma, augmenting the blood flow to the retina in the initial phases of the ailment could potentially yield advantageous outcomes [39]. Further research should also focus on the effects of KRG on other ocular diseases. Additionally, further studies are needed to identify the long-term efficacy and safety of KRG for the treatment of glaucoma. It is commonly thought that glaucoma is characterized by the enlargement of blood vessels and diminished blood circulation, which are significant risk elements that may lead to optic nerve damage in individuals with glaucoma. The efficacy of KRG in lowering intraocular pressure has been demonstrated, potentially mitigating the likelihood of optic nerve impairment. Further research should provide more evidence to support this hypothesis. The evidence indicates that ginsenosides derived from ginseng may potentially contribute to preventing age-related macular degeneration (AMD) due to their ability to inhibit TNF-a. This could suggest that KRG can be used to reduce the risk of AMD. Further studies are needed to confirm this hypothesis. Undoubtedly, inflammation is a principal risk factor associated with age-related macular degeneration (AMD). Therefore, further research into the effects of KRG as an anti-inflammatory agent could be beneficial in reducing the risk of AMD. Additionally, research into the long-term safety of KRG would be beneficial for determining its potential as an AMD prevention strategy. It is believed that patients suffering from conditions such as age-related macular degeneration, glaucoma or cataracts may benefit from ginseng's antiapoptotic and antioxidant properties. This could potentially assist in the retardation of the advancement of the ailment, mitigation of symptoms, and enhancement of the general visual capacity. Further investigation is required to establish the effectiveness of ginseng as a treatment for age-related macular degeneration (AMD). It is noteworthy that extensive research has been conducted on the advantageous impacts of ginseng for individuals with diabetes, encompassing the mitigation of blood glucose levels, regulation of weight gain, and augmentation of insulin secretion. Therefore, ginseng may have similar benefits for those suffering from AMD. It is also important to consider the safety of ginseng when using it as an AMD treatment. Further research is needed to assess the potential risks of using ginseng for AMD treatment. In a study that was conducted very recently, it was shown that ginseng treatment significantly reduced the amount of retinal oxidative stress that was caused by diabetes in mouse models, which were associated with diabetes. Nonetheless, it remains ambiguous whether this phenomenon holds for human beings. More studies need to be conducted to understand the long-term effects of ginseng on AMD. Many of the findings in this study were based on the fact that ginseng has antioxidative properties. Ginseng also has anti-inflammatory effects, which could help reduce the symptoms of AMD. Additional investigation is required to comprehensively comprehend the potential efficacy of ginseng as a treatment for age-related macular degeneration. Even though researchers have given more attention to the effects of ginseng on AMD and diabetes than to the effects of ginseng on cataracts caused by selenite in rats, ginseng has also been shown to have the ability to reduce the severity of cataracts caused by selenite. This suggests that ginseng may have potential benefits for people with cataracts. However, more studies are needed to confirm if ginseng can be used as a potential cataract treatment. Furthermore, a team of Korean researchers led by Lee et al. [43] have identified the non-saponin component of ginseng as one of the key agents responsible for preventing cataracts. Their research found that the non-saponin component of ginseng could block the damage caused by oxidative stress on the proteins in the eyes and ultimately reduce the risk of cataracts. Further research is required to validate the effectiveness of ginseng as a plausible remedy for cataracts. As a supplement, ginseng is an extremely promising compound for further investigation into the treatment of macular degeneration, diabetic retinopathy, and even cataracts in the future. In addition, ginseng has also been linked to improved visual acuity and contrast sensitivity, indicating potential benefits for treating age-related vision loss. Further research is needed to determine the full potential of ginseng for eye care. This is because ginseng is renowned for its potent antioxidant properties. Ginseng also contains compounds that are thought to have therapeutic effects on the eyes and can help protect the eyes from oxidative stress. It is also believed to reduce inflammation and improve blood circulation, benefiting eye health.

Resveratrol – Researchers have suggested that red wine's protective effects on human health could explain why France has a lower mortality rate than other countries due to the lack of cardiovascular diseases in the country. Researchers suggest this is linked to the French consuming much more red wine than other countries. This has led to studies into the potential health benefits of moderate red wine consumption. The findings indicate that red wine may confer health advantages, including a decreased cardiovascular disease risk. In red wines, large amounts of polyphenols can be found in them. Polyphenols possess antioxidative and anti-inflammatory characteristics, potentially mitigating the susceptibility to specific ailments. However, it is important to remember that these benefits are only achievable if red wine is consumed in moderation. It is widely believed that polyphenols are a class of compounds that are capable of exhibiting a variety of properties, including this phenomenon that involves the suppression of platelet aggregation, the production of eicosanoids that promote inflammation and blood clotting, and the hindrance of endothelin synthesis which triggers vasoconstriction. These properties can reduce the risk of coronary heart disease and other cardiovascular diseases. However, drinking too much red wine can have unwanted side effects, including an increased risk of liver disease, high blood pressure, and obesity. Additionally, too much alcohol can lead to impaired judgment, poor impulse control, and long-term health issues. Therefore, it is important to consume red wine responsibly in moderation. It is well known that red wines have particular health benefits for the cardiovascular system. Therefore, it is important to consume red wine in moderation and combine it with a balanced and healthy diet. Regular physical activity and other lifestyle factors can also help to maximize the health benefits of drinking red wine. The administration of resveratrol in mice that were subjected to a high-fat diet resulted in a noteworthy improvement in insulin sensitivity, a reduction in insulin-like growth factor-1 (IGF-I) levels, and an elevation in the activity of AMP-activated protein kinase (AMPK) and peroxisome proliferator-activated receptor gamma coactivator 1alpha (PCG-1alpha), which in turn has been shown to result in significantly longer survival and health [8]. The results of this study indicate that resveratrol could potentially and significantly impact the preservation of metabolic equilibrium and the mitigation of metabolic disorders. Further studies are needed to understand resveratrol's effects on metabolic health better. Additionally, it is important to consider the potential side effects of the long-term use of resveratrol supplements. Furthermore, resveratrol has also been shown to reduce inflammation and improve mitochondrial health. Thus, it is possible that resveratrol could be beneficial for overall health and well-being. However, more research is needed before any definitive conclusions can be made. The researchers also found that supplementation with resveratrol reduced oxidative stress, vascular endothelial growth factor, and the development of early vascular lesions in rat and mouse models of diabetes [32]. However, there is still debate over the efficacy of resveratrol as a supplement. Additionally, more research is needed to determine the potential long-term effects of resveratrol supplementation. In patients with diabetic retinopathy, this quality may be helpful due to its ability to delay or even stop the death of cells. Despite these potential benefits, resveratrol must be studied further before it can be recommended as a treatment for any condition. Further research is needed to confirm the potential benefits of resveratrol supplementation. As a result of inhibiting CHOP and IRE1 expression, resveratrol prevented injury-induced capillary degeneration and endoplasmic reticulum stress in rats. However, further studies are needed to determine the long-term effects of resveratrol supplementation. Additionally, studies should be conducted to assess the efficacy of resveratrol in humans. It was demonstrated by the fact that it could protect the body against both conditions. Thus, it is likely that resveratrol could be used as a therapeutic agent to treat conditions associated with capillary degeneration and endoplasmic reticulum stress. Further research is needed to explore the potential of this promising compound further. There is some evidence that resveratrol may be able to be a novel drug in terms of treating vascular dysfunction in the retina [71]. However, animal studies have shown conflicting results. More research is needed to confirm the effectiveness of resveratrol in humans. Additionally, further investigation is required to assess the compound's safety over an extended period. This is because retinal ischemia plays a significant role in the development of closed-angle glaucoma and diabetic retinopathy, as well as other types of eye diseases. Thus, it is imperative to evaluate the effectiveness of resveratrol and appraise the possible hazards linked to its prolonged consumption. Further research is needed to clarify the effects of resveratrol on eye health. There is no doubt that resveratrol is an efficient antioxidant and that the potential benefit of this substance lies in its ability to mitigate the oxidation of low-density lipoproteins (LDLs), thereby conferring cellular protection against the deleterious effects of free radicals. However, more research is needed to fully understand the potential risks of the long-term use of resveratrol on eye health. Additionally, further studies should be conducted to determine the optimal dosage for humans. Additionally, the compound resveratrol has exhibited potential in promoting increased blood flow, which may be a preventative measure against vessel damage and apoptosis of optic nerve cells in individuals with glaucoma. The results of these studies could help guide further research into the potential therapeutic uses of resveratrol for eye health. Additionally, these findings could be used to develop new treatments for glaucoma and other eye diseases. It has been shown that resveratrol, the induction of heme-oxygenase-1 and the inhibition of pro-oxidant intracellular heme effects, neuronal cell cultures following strokes were observed to exhibit a mitigated response, provide neuroprotection and demonstrate a novel pathway for cellular neuroprotection [90]. These findings provide evidence of the potential for resveratrol to treat glaucoma by protecting the neural cells from oxidative damage. Further research is needed to investigate the cellular mechanisms of resveratrol-mediated neuroprotection further. The administration of resveratrol as a supplement to rats resulted in a reduction of malonyl dialdehyde levels and an increase in glutathione levels in the lens. This study also revealed that resveratrol supplementation effectively suppressed selenite-induced oxidative stress and the development of cataracts. Further studies are needed to uncover which pathways are regulated by resveratrol and how to optimize the dose and timing of resveratrol for maximal neuroprotection. Additionally, human safety and efficacy trials are needed to confirm these findings. Because oxidative stress plays a crucial role in the pathophysiology of significant ocular ailments, including cataracts, age-related macular degeneration, glaucoma, and diabetic retinopathy. The characteristics of resveratrol may hold significant potential in creating innovative therapeutic approaches and preventative measures for these conditions. Further research is needed to explore the full potential of resveratrol as a therapeutic and preventive agent for major ocular diseases. Studies should focus on the long-term administration of resveratrol and its effects on ocular health. Ultimately, these studies may lead to novel treatments and preventive interventions. *Salvia miltiorrhiza*, also referred to as Asian red sage or Danshen, comprises salvianolic acid B. This potent polyphenolic antioxidant is water-soluble and possesses anti-inflammatory properties. Danshen is also known as *Salvia miltiorrhiza*. A diabetic retinopathy mouse model was used in a recent investigation conducted to examine the impact of intravenous administration of Danshen. Ischemia of the blood capillaries is one of the most serious complications that can arise from DR. This condition is characterized by a change in structure; the thickening of the basement membrane of the capillaries induces the condition. Under such circumstances, the prompt elimination of oxygen radicals following ischemia is hindered, which destroys the permeability membrane and the formation of edema due to the destruction of nerve cells due to lipid peroxidation. This can permanently damage the capillaries, decreasing the organ's oxygen supply. Furthermore, this can cause organ failure and other serious health issues. The administration of Danshen to hypoxic and ischemic retinal tissues may facilitate the restoration of blood-oxygen transportation, enhance the absorption of retinal hemangiomas, and consequently avert visual impairment if it is injected into the tissues of the retina that are suffering from hypoxia and ischemia. There is also evidence that Danshen may help patients with diabetes maintain healthy blood sugar levels by scavenging free radicals [88]. There has also been evidence that Danshen is also beneficial for treating glaucoma, with intravenous use of Danshen after glaucoma treatment resulting in a reduction of retinal ganglion cell damage as a result of intravenous use of Danshen. Danshen has been suggested to have the potential to stabilize the visual field during the middle to late stages of glaucoma based on the outcomes of prior clinical trials. In other research, in rabbits, Danshen has demonstrated the ability to prevent the mortality of retinal ganglion cells and suppress the activation of nuclear factor kappa B (NF-kB) by the inflammatory protein TNF-[89]. Like ginseng, Danshen's neuroprotective mechanism may operate through the inhibition of NMDA receptor antagonist activity, similar to how ginseng protects neurons. This suggests that Danshen could be a prospective therapeutic intervention for neurodegenerative disorders, including but not limited to Alzheimer's and Parkinson's disease. Additional investigation is required to ascertain the effectiveness and safety of Danshen for human consumption. The results of preclinical studies conducted on patients suffering from ocular diseases involving oxidative stress have shown promising results for Danshen. Clinical trials conducted in humans are now needed to explore the therapeutic potential of Danshen further. If results prove successful, Danshen could provide an effective and safe treatment for neurodegenerative diseases. Among the most common diseases are diabetic retinopathy, age-related macular degeneration, and cataracts. Danshen has been shown to reduce inflammation in the eye's blood vessels. It also helps to improve vision and protect the retinal cells from further damage caused by oxidative stress. Furthermore, it could potentially mitigate the likelihood of ocular disease-induced visual impairment.

Quercetin **–** Researchers have paid the most attention to quercetin as one of the flavonoids, and a diverse array of plant-based sources, including but not limited to Brassica vegetables, black and green teas, and various types of berries, contain this particular nutrient, which are all great sources of this flavonoid. Quercetin is acknowledged for its anti-inflammatory characteristics and has been associated with a decreased susceptibility to specific categories of cancer and cardiovascular ailments. Additionally, it may also have the potential to improve cognitive performance. Researchers found that populations with diets rich in flavonoids, such as those located in the Mediterranean region, tend to have lower rates of cardiovascular disease and are more likely to live longer than those with diets low in flavonoids [22], which sparked an interest in flavonoids. Studies have suggested that flavonoids can improve memory, focus, and attention. Moreover, flavonoids have also been linked to improved mood, enhanced cognitive function, and reduced cognitive decline. Much research has been conducted on quercetin's anti-inflammatory and antioxidative properties [82]. However, there are currently no medications based on quercetin; these products have received approval from the regulatory body known as the Food and Drug Administration. Quercetin is a type of flavonoid that has been found to have many health benefits. More research is needed to understand the potential benefits of quercetin and how it can be used to treat various illnesses. Research on the protective effects of quercetin was demonstrated in the retinal cell line ARPE-19 by demonstrating its ability to inhibit proinflammatory molecules and directly inhibit the intrinsic apoptosis pathway of the cells. Further research is needed to understand the effects of quercetin on human cells and its potential use as a therapeutic agent. Currently, quercetin can be found in various supplements and dietary sources. The findings of an in vitro study involving RF/6A rhesus choroids-retinal endothelial cells indicate that the administration of quercetin led to a dose-dependent reduction in the migration and tube formation of the cells. These results suggest the potential of quercetin to be used as an anti-angiogenic agent in the treatment of retinal diseases. Further studies need to be conducted to evaluate the effects of quercetin on human cells in vivo. Those two processes are crucial to the phenomenon of retinal angiogenesis, which is a distinctive hallmark of age-related macular degeneration and is the subject of inquiry. Therefore, quercetin could be a promising therapeutic agent for treating age-related macular degeneration. Further research should also be done to evaluate the efficacy and safety of quercetin for other retinal diseases. The administration of quercetin after oxidative damage exhibited a dose-dependent reduction in cellular damage and senescence. The findings of this investigation indicate that quercetin exhibits promise as a viable therapeutic intervention for managing age-related macular degeneration and other retinal pathologies. Additional investigation is required to comprehensively comprehend the effectiveness and safety of quercetin for these medical conditions. Additional research involving human RPE cells grown in culture further demonstrated that this was the case. Quercetin also showed protective effects on the human RPE cells against oxidative stress, indicating its potential as a therapeutic agent for retinal diseases. Further research should be conducted to investigate the effects of quercetin on human RPE cells in vivo. It has also been shown that quercetin (along with other natural flavonoids) significantly decreased the production of reactive oxygen species (ROS) in retinal cell cultures that were subjected to oxidative stress as a result of ascorbate and $Fe+2$ [5]. This suggests that quercetin may be useful in treating and preventing retinal diseases caused by oxidative stress. Further research should explore the potential of quercetin to reduce ROS production in vivo. According to a study, human umbilical vein endothelial cells (HUVECs) were used to determine the effect of quercetin in reducing human umbilical vein endothelial cell viability following exposure to oxidants. The study's findings indicate that quercetin can mitigate oxidative stress and cellular apoptosis in HUVECs. The results of this study indicate that quercetin may possess the ability to act as a potent agent in mitigating oxidative stress and safeguarding the retina against harm. Researchers have also studied the effects of quercetin on laser-induced choroidal neovascularization in vivo, finding that quercetin significantly reduced the size of the choroidal neovascularization compared to untreated controls when compared to untreated controls. These results demonstrate the potential for quercetin to be an effective treatment for reducing the risk of vision loss caused by laser-induced choroidal neovascularization. Further research is needed to determine the long-term efficacy of quercetin in clinical settings. Quercetin was observed to impede the expression of heat shock proteins, particularly HSP72, in rat models of glaucoma, thereby hindering the neuroprotective properties of these proteins in the models above. This suggests that quercetin may have a detrimental effect on the vision of glaucoma patients. Therefore, further research is necessary to understand healthfully quercetin's implications on vision. Even though there is some evidence that quercetin may have anticataract effects, scientists have not yet understood the exact mechanisms by which this may be achieved [35, 61, 64, 65, 67, 70]. Hence, additional investigation is required to explore the potential of quercetin in safeguarding visual function. Additionally, more studies should be conducted to evaluate the safety of quercetin in long-term use. The compound also acts as an antioxidant, modulating glycation, epithelial cellular signaling, calpain protease activity, and sorbitol-aldose reductase activity [79]. Additional research should be conducted to explore the other potential benefits of quercetin. Furthermore, the impact of quercetin on different age groups should be studied to determine its efficacy in different populations. In fact, due to its ability to inhibit aldose reductase, quercetin served as a gold standard for cataract inhibition in 2011 when Gacche and Dhole tested the abilities of other flavonoids that also showed similar abilities. Further research on the efficacy of quercetin for cataract inhibition is needed to determine the full extent of its potential to improve vision. Long-term studies should be conducted to assess the impact of quercetin on different age groups over time. The precise mechanisms underlying the impact of quercetin on cataract formation and its effect on the eye's lens remain unclear, despite its status as the most prevalent flavonoid in the human diet and the existence of multiple plausible pathways for its physiological activity [41, 81]. More research is needed to understand how quercetin affects eye health and vision. In particular, more research is needed to understand its long-term effects on different age groups. Also, studies should be conducted to determine whether quercetin can prevent or treat cataracts. Although there is significant evidence associating quercetin and other flavonoids with medical benefits, particularly regarding ocular health, additional research is necessary to establish the suitability of this promising compound as a therapeutic intervention for ocular inflammatory diseases and cataracts. Additional research is warranted to explore the impact of quercetin on various ocular ailments. It is recommended that clinical trials be undertaken to assess the safety and efficacy of quercetin in the treatment of various ocular conditions.

6 Conclusion

Finding evidence to support the use of complementary and alternative medications is difficult. Still, nutritional supplements and herbal remedies are easily marketed in popular culture as promoting health benefits. While these medications may not have been proven effective, many people take them to improve their health. However, it is essential to understand the risks associated with taking these medications and the potential for interactions with other medicines. As a result of patients with eye diseases frequently using complementary and alternative medicine (CAM) products, ophthalmologists must be knowledgeable about the appropriate use of these products in common eye diseases. They should also be aware of potential adverse events or interactions associated with using CAM products. Furthermore, healthcare providers should be mindful of the potential for additive effects when CAM products are used concomitantly with traditional medications. Several studies have shown that specific antioxidant vitamins and zinc can significantly reduce the progression of age-related macular degeneration (AMD) in patients by slowing retina deterioration. Therefore, healthcare providers should be knowledgeable about the potential benefits of CAM products and should consider recommending them to patients who may benefit from them. Additionally, healthcare providers should educate patients on adequately using the potential risks associated with using complementary and alternative medicine (CAM) products. As a result of the reviewed studies, antioxidant vitamins and mineral supplements are not currently supported by evidence in the literature about their effectiveness in preventing or treating cataracts in healthy individuals. Therefore, healthcare providers should discourage their use, as they may be a waste of money and resources. Patients should be aware that using said products carries potential hazards, and there is a dearth of substantiating evidence regarding their effectiveness. In both diabetic retinopathy and glaucoma research, these products demonstrate no benefit. Patients should be encouraged to discuss with their healthcare provider any alternative treatments that are evidence-based and offer a better chance of success. Furthermore, healthcare providers should stay current on the latest research to make the best patient decisions. The challenges associated with later studies on the effects of antioxidants on cataract development and progression are attributed to several factors. These include the variability within and between study populations, inadequate definition of subjects' lifetime exposure to antioxidants, reliance on self-reported dietary intake, imprecise assessment of antioxidant nutrients, variations in the doses and formulations of vitamins used in different studies, and the duration of the follow-up period required to evaluate cataract development and progression. Therefore, it is difficult to draw definitive conclusions from studies on the association between antioxidant vitamins and cataract risk. Further research is needed to understand the potential role of antioxidants in cataract prevention. In terms of determining whether herbal remedies can be used in the treatment of eye diseases, currently, there exists a dearth of observational studies or prospective clinical trials that satisfy the prerequisites for level I or level II evidence. Thus, more research is necessary to assess the efficacy and safety of herbal remedies in treating eye diseases. Further studies should also evaluate the role of antioxidants in cataract prevention. Consequently, it presents a challenge to formulate any definitive inferences regarding the effectiveness of herbal remedies in addressing ocular ailments. Given the lack of reliable evidence, caution should be exercised when using herbal remedies to treat eye diseases. Further research should focus on the potential short- and long-term effects of herbal remedies on eye health.

Additionally, more research is needed to explore the potential of herbal remedies in preventing eye diseases.

Acknowledgment We would like to extend our sincere appreciation and gratitude to the Department of Agronomy at the School of Agriculture at Lovely Professional University, Punjab, 144411, India.

Abstract

This chapter discusses the phytochemical constituents and metabolites in some medicinal plants and herbal remedies used in the treatment and management of injuries. A meta-analysis was conducted to identify the studies that investigated the chemical composition and biological activity of these natural remedies. The medicinal plants and herbal medicine included in the review were chosen for their traditional use in wound healing and were found to contain a range of phytochemicals with known medicinal properties, such as flavonoids, terpenoids, alkaloids, and saponins. These phytochemicals have been proven to exhibit antioxidant, anti-inflammatory, and wound-healing activity in various in vitro and in vivo studies. In addition, the review identified several metabolites produced by these medicinal plants and herbal medicine that may contribute to their therapeutic effects. Overall, the results of this review suggest that medicinal plants and herbal medicine may be valuable sources of phytochemicals and metabolites with medicinal properties, and encourage their usage in the treatment and management of wounds. However, further research is needed to fully understand the mechanisms of action and potential therapeutic effects of these compounds. This involves research into the best doses and combinations of natural remedies for various sorts of wounds, along with research into their safety and effectiveness in clinical settings.

Keywords

Wound healing · Antioxidant activity · Traditional medicine · Therapeutic effects · In vitro · Flavonoids

Abbreviations

5-LOX	5-lipoxygenase
ALT	Alanine transferase
AMPK	Activated protein kinase
AST	Aspartate aminotransferase
BC	Before Christ
bFGF	Basic fibroblast growth factor

CADs	Cichoric acids
CC	Creative Commons
CFE	Calendula flower alcohol extracts
CFS	Chronic fatigue syndrome
COX-2	Cyclooxygenase-2
DCQA	Dicaffeoyl quinic acid
DPPH	2,2-Diphenyl-1-picrylhydrazyl
EGF	Epidermal growth Factor
ET-1	Endothelin-1
GABA	Gamma amino butyric acid
HB-EGF	Heparin-binding epidermal growth factor-like growth factor
HPA axis	Hypothalamic–pituitary–adrenal axis
IFN-γ	Interferon gamma
IGF-1	Insulin-like growth factor-1
IL-1β	Interleukin-1 beta
IL-6	Interleukin-6
KGF	Keratinocyte growth factor
MCF	Monocyte chemoattractant protein
MIP	Macrophage inflammatory protein
MMP	Matrix metalloproteinase
MPP	1-Methyl-4-phenylpyridinium
MTT	(3- [4,5-Dimethylthiazol-2-yl]-2,5 diphenyl tetrazolium bromide)
NF-yB	Nuclear factor y B
NF-κB	Nuclear factor kappa B
NK cells	Natural killer cells
NO	Nitric oxide
NrF2	Nuclear factor erythroid 2-related factor
O/W	Oil-in-water
PCL	Polycaprolactone
PDGF	Platelet-derived growth factor
PGE2	Prostaglandin E2
ROS	Reactive oxygen species
STAT3	Signal transducer and activator of transcription 3
TGFs	Transforming growth factors
TGF-α	Transforming growth factor alpha
TGF-β	Transforming growth factor beta
TIMPs	Transforming inhibitors of metalloproteinases
TNF-α	Tumour necrosis factor alpha
TRPA 1	Transient receptor potential ankyrin 1
TRPV 1	Transient receptor potential cation channel subfamily V member 1
UVB rays	Ultraviolet B rays
VEGF	Vascular endothelial growth factor
VPF	Vascular permeability factor

1 Introduction

The largest organ in the body is the skin. The protection against physical harm from the environment, control of body temperature, and sensitivity to stimuli are just a few of the important jobs that skin performs. It serves different functions, and any harm or injury makes the organism more vulnerable to other biological and physical dangers, leading to the wound. A wound is a type of injury to the human body which forces the skin to break and subsequently damages the affected underlying tissue [1].

Herbal medicines, also known as phytomedicine, include herbs (such as seeds, leaves, bark, and roots), herbal materials (such as essential oils, and fresh juices), herbal preparations (such as tinctures, extracts, and fatty oils), and completed herbal products. It is a chemical compound combination from multiple chemical classes, the bioactivity of which combine to produce effects as a result of combining activities of the individual components [2, 3]. Additionally, other inert compounds serve as ballast or fillers. The medicine in question is therefore a complex mixture, both chemically and in relation to how different bioactivities interact to generate a particular effect. Contemporary synthetic drugs are very expensive, sometimes dangerous, and have withdrawal symptoms that come back. Nonetheless, because they come from a natural source and already have been utilized from the beginning of time, herbs are typically claimed to be safe [2]. Herbal medicine has been utilized for centuries to treat an array of ailments [4, 5], and it remains a popular choice for people seeking natural remedies [6]. At the locations of injury, wounds are the rupture of the anatomical and functional continuity of cells and tissues. They may be brought on by mechanisms that damage the tissue physically, chemically, microbiologically, or immunologically [7]. Each year, 14 million persons are projected to suffer from burns and wounds, with more than 80% living in countries with low and moderate incomes [7]. Nevertheless, this might be underreported because wounds are an everyday event which can befall anybody any time, and burns and minor wounds are not always treated medically.

The skin protects our bodies against both chemical and physical harm, as well as loss of water, and assists in maintaining homeostasis in the body. In everyday life, skin damage occurs when the skin fails in its defensive role, resulting in the emergence of an injury on the surface of the skin. The skin defends our internal body system against the outside world, and thus regulates temperature and maintains homeostasis. To sustain its functions after damage, the skin's integrity must be restored [8]. A complex circulatory and neural network connects the outer epidermis, dermis, and lower subcutaneous layer of human skin. The epidermis, located on the outermost layer, is primarily made up of keratinocytes, which establish an airtight barrier for protection alongside Langerhans cells, melanocytes, and Merkel cells [9]. The dermis is located beneath the epidermis and is connected to it by the basement membrane, which is a slim layer of extracellular matrix (ECM) composed primarily of collagen IV, integrins, perlecan, laminins, and nidogen [10]. The dermis has a complex composition that differs quite significantly from the epidermis [10]. It is made up of a slim layer of extracellular matrix (ECM), which serves as a framework for hair follicles, fibroblasts, sweat glands, blood vessels, and other mesenchymal cells. Additionally, it contains chemicals that modulate homeostasis, such as enzymes and growth factors [11]. The dermis is further divided into multiple layers, with the papillary layer nearest to the basement membrane and made up of poorly organised thin collagen fibres that house a dense population of fibroblasts [12]. The skin's complexity makes it extremely challenging to duplicate in a laboratory environment.

The tear and exposure of the skin could end up in illnesses and lesions, which could give rise to severe diseases and possibly fatality. As a result, one of the main subjects in medical research on wound treatment is how to repair these wounds in as little time as possible and with the lowest possible level of effect on the wound in regards to appearance [13, 14].

The aim of this chapter is to explore the phytochemical constituents and metabolites present in medicinal plants and herbal remedies used in the treatment and management of injuries, with a focus on their traditional use in wound healing. The objectives of this chapter are to identify the various phytochemicals present in these natural remedies, examine their biological activity, and evaluate their potential therapeutic effects on wounds.

To achieve the aims and objectives of the chapter, the authors have conducted a meta-analysis of studies that have investigated the chemical composition and biological activity of medicinal plants and herbal remedies used in wound healing. The traditional use of these natural remedies and various phytochemicals and metabolites present in these remedies that may contribute to their therapeutic effects have also been identified and examined. In addition, the in vitro and in vivo studies that support the antioxidant, anti-inflammatory, and wound-healing activity of these phytochemicals have been discussed.

The chapter is organized into different sections that discuss the phytochemicals and metabolites present in medicinal plants and herbal remedies used in wound healing. Each section focuses on a specific class of phytochemicals, such as flavonoids, terpenoids, alkaloids, and saponins. The biological activity of these compounds and their potential therapeutic effects on wounds have also been evaluated.

The information used in this chapter was sourced from various peer-reviewed journals, scientific databases, and books. The information presented in this chapter is supported by a meta-analysis of studies that have investigated the chemical composition and biological activity of medicinal plants and herbal remedies used in wound healing. The authors have also relied on traditional knowledge and practices, as well as modern scientific research, to support the use of these natural remedies in wound healing.

1.1 Herbal Medicine Classifications

According to Balap and Gaikwad [2], there are three main classifications of herbal medicine:

- Chinese herbal medicine
- Western herbal medicine
- Traditional Indian medicine
- Chinese herbal medicine: The oldest traditional treatise known to exist on the topic was written by Huang-ti, the Yellow monarch (2697–2597 BC), who is responsible for coordinating and standardizing Chinese herbal remedies. Due to the health benefits of both, the majority of Chinese herbalists combine one principal herb with a diet. The Indian subcontinent employs herbalism in the same manner. In Chinese medicine, there are four main ways to combine herbs. When two or more herbs are used together to complement one another's effects on the body, complementary herbs are used. Herbs that are helpful have different uses and effects. When the other herb gives supportive catalysis, one herb takes the initiative. Herbs of fright lessen the risk of wound by reducing the ferocity and power of partner herbs in an admixture. Cancelling herbs, that is, a mixture of laxative and astringent herbs, are employed in reducing constipation caused by the latter. Herbs used to reduce constipation caused by such injury are utilized to remove unwanted side effects [2].
- Western herbal medicine: Before the twentieth century, Western herbal medicine predominated the medical landscape; however, conventional or inorganic medicine founded on scientific medical models has since supplanted it. The general public's attitude towards conventional medicine has changed recently, though. The bilious, sanguine, choleric, and melancholy temperaments, which determine the makeup of the patient, the level of cold, wet, heat, or dry administered to sickness conditions and herbs, and Hippocrates' sense of humour were the foundations of European herbalism until the seventeenth century.
- Traditional Indian medicine: Traditional Indian medicine, also regarded as Ayurvedic medicine, is an ancient Indian health system that focuses on general healthcare, medicine, dietary guidance, and health education. Ayurveda medicinal system is founded on the three distinct biotic humours of Vata, which are Pitta (fire), (air), and Kapha (water). These tridoshas are present in everyone, but one element is constitutionally dominant. The primary factor defines the constitutional strengths and limitations. Vata is known for its lack of power and stamina, as well as breathlessness, indigestion, bloating, and circulation problems [15].

1.2 Traditional Use of Herbal Remedies in Wound Healing

Herbs are frequently used in combination in traditional medicine to produce a synergetic effect. It implies that the effects of numerous plants combined together can be larger when compared to the effects of each individual herb alone. This is known as a 'herbal preparation' or 'herbal formula' and is a regular technique in traditional medicine.

Traditional healers in various cultures possess a plethora of knowledge regarding the application of medicinal herbs in wound healing. They have established specialized procedures and methods for producing and applying herbal treatments, which they frequently combine with other therapies like massage, dietary modifications, or acupuncture.

One advantage of employing herbal therapies for healing wounds is that they may be adjusted to the needs of the individual. Practitioners of traditional medicine frequently consider the patient's general state of health and welfare, as well as specific wound features such as severity, location, and type. This personalized approach can aid in the process of healing and encourage a faster recovery.

An additional benefit of medicinal herbs is that they are frequently less expensive and easier to obtain than prescription drugs or medical treatments. A lot of herbs can be cultivated in the garden or bought at agricultural markets or natural food shops. This could make them an especially enticing choice for people who prefer a natural healing approach or those who do not have access to medical services.

The field of science has begun to understand the phytochemical components and metabolites that give these plants their medicinal properties [16]. Studies have demonstrated that substances such as polysaccharides, flavonoids, triterpenoids, and curcumin have anti-inflammatory and wound-healing properties [16]. With this knowledge, medicinal plants can be used effectively to treat and manage wounds, which helps to improve the healing process.

2 Wound Classification

Wounds are often categorized based on the underlying aetiology of wound development. They include the following.

2.1 Acute Wounds

Acute wounds are those that recover completely within 5–10 days, and at most, within 30. Acute wounds typically happen during surgery or due to acute tissue injury. Trauma (such as burns or injuries), a subsequent disease condition (such as leg ulcers), or a mix of both can result in acute skin lesions [17]. These wounds heal on their own using a prompt and systematic healing process that returns the skin's structural and functional integrity [18]. In contrast to chronic wounds, which take months to fully recuperate, acute wounds take just a few weeks. A recent injury that has not gone through the wound-healing stages is characterized as an acute wound. These might be superficial wounds that involve both the dermis and the epidermis, or extend beyond these layers and cause damage to the skin that compromises the subcutaneous layer [16]. Tissue damage/injury in an acute wound typically takes place throughout a systematic, phase of time correction that successfully restores functional and anatomical integrity. Cuts or surgical incisions frequently result in acute wounds [19].

2.2 Closed Wounds

Closed wounds allow blood to exit the circulatory system, but it still remains within the human body and includes contusions or abrasions, hematomas or blood tumours, and crush injuries [20]. Bumps and bruises make it obvious [21].

2.3 Open Wounds

In this scenario, blood leaks out with obvious bleeding from the person. It is further classified as follows: incised wounds, laceration or tear wounds, puncture wounds, abrasions or superficial wounds, and penetration wounds.

2.3.1 Incised Wounds

This wound has minimal tissue damage and no tissue loss. Sharp instruments like scalpels and knives are the major culprits.

2.3.2 Laceration or Tear Wounds

This non-surgical injury, when combined with other types of stress, causes tissue damage and loss.

2.3.3 Puncture Wounds

They are brought about by an object puncturing the skin, like a needle or a nail. Infection is common in these wounds because dirt can seep deep into them.

2.3.4 Abrasions or Superficial Wounds

Abrasion results from slipping on a rough surface. The top layer of skin, or epidermis, is scraped off during this process, exposing nerve endings and causing a painful injury.

2.3.5 Penetration Wounds

Penetration wounds are generally the result of an item, for instance, a knife, passing through the skin.

2.3.6 Gunshot Wounds

They often result from a bullet or similar projectile that enters the body.

2.4 Chronic Wounds

These wounds do not pass via the typical healing phases and have instead progressed to a level of pathological inflammation. They require a longer time to heal or they become recurrent [22] (Fig. 1).

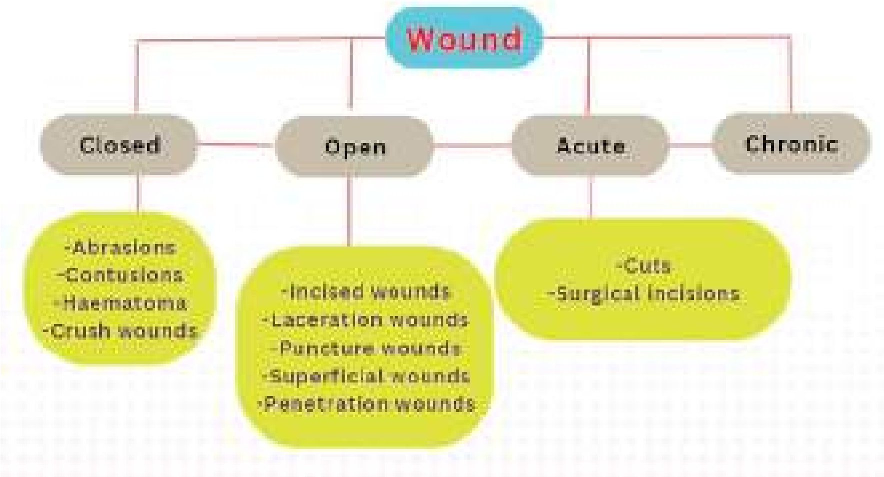

Fig. 1 Types of wound summarized

3 Wound Healing

Wound healing is a complicated process which comprises the interaction of various cell types, inflammatory mediators, and extracellular matrix components, and also several signalling pathways [23]. It is defined by a well-coordinated series of activities aimed to restore the skin's mechanical integrity and barrier function [24]. Tissue damage initiates healing, and this has four time-dependent phases: haemostasis, inflammatory, proliferative, and remodelling phases [25] (Fig. 2).

3.1 Haemostasis Phase

Coagulation and haemostasis occur immediately after injury to prevent bleeding [18, 19]. These mechanisms necessitate a series of interconnected procedures to secure blood vessels and establish matrixes for cell influx required in the latter stages of the healing process [20, 21]. Extrinsic and intrinsic routes trigger the coagulation cascade, resulting in platelet aggregation and the formation of clots [19]. During haemostasis, three steps occur in rapid succession. The first reaction is vascular contraction, which happens when blood vessels constrict to reduce the loss of blood. In the second step, platelets attach within a few seconds of a blood vessel's epithelial wall rupturing to establish a temporary plug over the vessel wall breach. Collagen, when exposed at the injury location, enhances platelet adhesion to the wound site. The third and last phase is blood clotting, often known as coagulation. The coagulation cascade, also regarded as secondary haemostasis, is defined as a set of stages

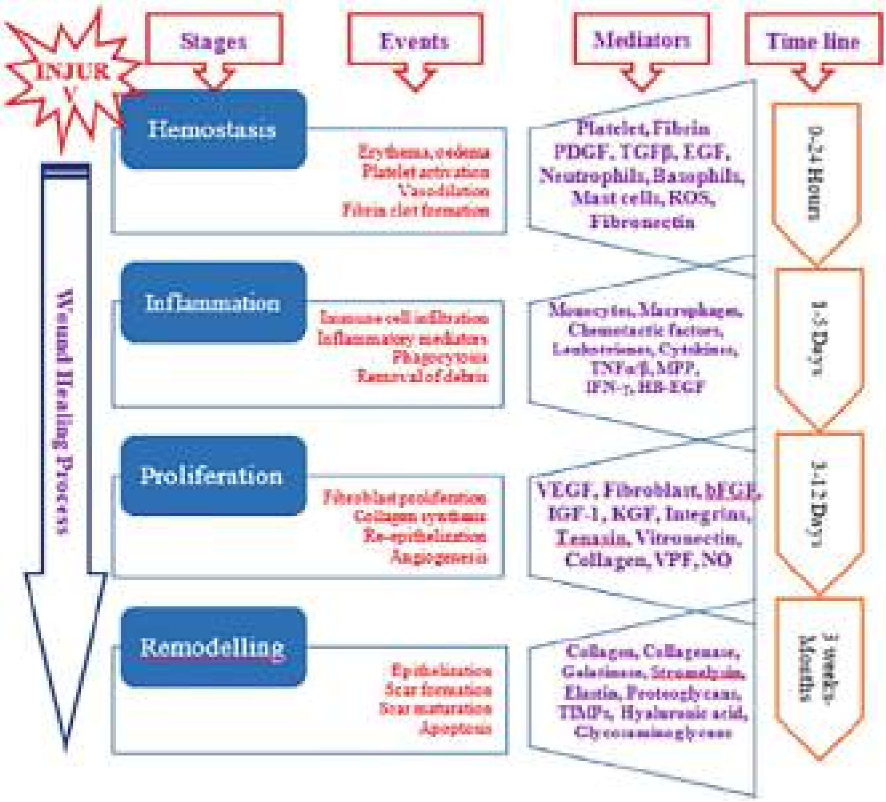

Fig. 2 Schematic representation of wound-healing phases and mediators involved [26]. (Adapted from Khaire et al. [26]. "An Insight into the Potential Mechanism of Bioactive Phytocompounds in the Wound Management" by Manisha Khaire is licensed underCCBY4.0)

that occurs as a result of tissue injury-induced bleeding, with each step activating the next and eventually producing blood clots. Coagulation strengthens the haemostatic plug by forming fibrin threads, which act as 'molecular glue'.

It takes around 60 s for the first set of fibrin strands to entangle with the wound. The fibrin-rich platelet block is completely established after a few minutes [19–22]. Growth factors derived from platelets, also known as platelet-derived growth factors, with cytokines also aid wound healing by activating/triggering and recruiting neutrophils, endothelial cells, fibroblasts, and macrophages [17, 21].

The phytochemicals and metabolites of medicinal herbs have been found to possess different effects on the different stages of wound healing. For example, flavonoids exhibit anti-inflammatory and antioxidant effects, which can promote the early wound-healing stages [23]. Triterpenoids, on the other hand, have been found to have qualities that reduce inflammation and promote healing [25]. Man can heal wounds in situ via continuous tissue regeneration and repair [27]. Curing chronic and acute wounds, along with burn wounds, follow the same basic steps: haemostasis, inflammation, propagation, fibroplasia, deposition of collagen, re-epithelialization, contraction, remodelling, and maturation [28]. The skin's ability to regenerate and restore the barrier function to the external environment after tissue damage is critical for survival. Healing of wounds is crucial following surgical incisions, burns, and chronic ulcers [29].

3.2 Inflammatory Phase

This is divided into two stages: the early inflammatory phase and the late inflammatory phase [30]. The early inflammatory phase/stage initiates molecular mechanisms which result in the infiltration of neutrophils at the site of the wound, whose primary objective is to avert infection [31]. Several chemoattractive drugs begin to attract neutrophils to the site of the wound within 24–36 h of damage. Neutrophils are responsible for the removal of foreign substances, microbes, and injured tissue from wounds by producing oxygen-derived free radicals and proteolytic enzymes [32].

The neutrophils are evacuated from the area once the task is finished. Then macrophages arrive at the injury site and carry on with the phagocytosis before moving on to the next healing phase in the course of the late inflammatory phase. Macrophages are crucial regulatory cells that store a considerable number of powerful growth factors in subsequent stages of the inflammatory response [31]. Lymphocytes are the last cells to arrive at the wound area (in the course of the late inflammatory phase), and they perform a vital role in the control of collagenase they are later on necessary for remodelling of collagen, extracellular matrix component formation, and breakdown [30].

3.3 Proliferative Phase

The proliferative phase includes the key healing mechanisms and begins three days following the injury, and goes on for about a fortnight. After the injury, myofibroblasts and fibroblasts multiply for the first three days in the surrounding tissue [33] prolyl moving into the wound, drawn there by substances like platelet-derived growth factors (PDGFs) and transforming growth (TGFs), which are generated by platelets and inflammatory cells [34]. When fibroblasts enter the wound, they proliferate rapidly and begin to deposit the new extracellular matrix by generating matrix proteins which include type 1 and 3 procollagen, proteoglycans, fibronectin, and hyaluronan. The synthesis of collagen is a critical event. Moreover, collagen is a critical part of all wound-healing stages because it helps to maintain wound integrity [16].

3.4 Remodelling Phase

Scar tissue production occurs through wound remodelling (Fig. 3d, above) and is finished in roughly one year or more [35]. Once the lesion heals, capillary growth ceases, fibroblast and macrophage density is decreased by apoptosis, and blood supply and metabolic process diminish [35]. The result is a developed scar with fewer blood vessels, cells, and a strong tensile strength [30]. Though the majority of injuries are the consequence of basic wounds, local and systemic factors can change and slow down the finely regulated process of repair, resulting in injuries whose healing is not orderly and timely, and grow into non-healing, chronic wounds. Consequently, they are classed as either chronic or acute wounds subject to the tissue's capacity to mend the injury [16].

4 Some Facts About Chronic and Acute Wounds

Though chronic wounds take several months to heal, acute wounds require just a few weeks to recover entirely. A fresh wound that has not yet developed via successive wound-healing stages is classified as an acute wound. These might be superficial wounds that involve both dermis and epidermis or full-thickness damage to the skin that compromises the hypodermal layer. Surgical incisions, abrasions, lacerations, and thermal wounds are all examples of acute wounds. They heal promptly via the regular inflammatory process, new tissue formation, and remodelling. Growth factors, together with cytokines that are released close to the injury site, regulate the healing of the acute wound [36].

On the other hand, chronic wounds do not heal normally and are not treated in a timely and organized manner [37]. The healing process is incomplete and disrupted by different circumstances that cause haemostasis, inflammation, propagation, or remodelling to be delayed by one or more stages [16]. Tissue hypoxia, infection, exudate, necrosis, and high inflammatory cytokine levels are instances of such causes [38]. The injury's continuous inflammatory state leads to a response by the tissue in a cascade format which, when combined, keeps the injury from healing. These wounds usually relapse because the procedure of healing is disorganized and the anatomical and functional outcomes are poor [37]. Different factors, like neuropathic disorders, venous and arterial insufficiency, high blood pressure, vasculitis, and/or burns, cause chronic wounds [39] (Fig. 4).

5 Herbs Utilized in Herbal Medicine for the Treatment of Wounds

Plants have been used for therapeutic purposes by humans throughout the course of time. Herbal medicine, also referred to as phytotherapy, is an ancient practice which treats numerous health ailments with plants and their extracts. Accidents, burns, and surgeries can all result in wounds.

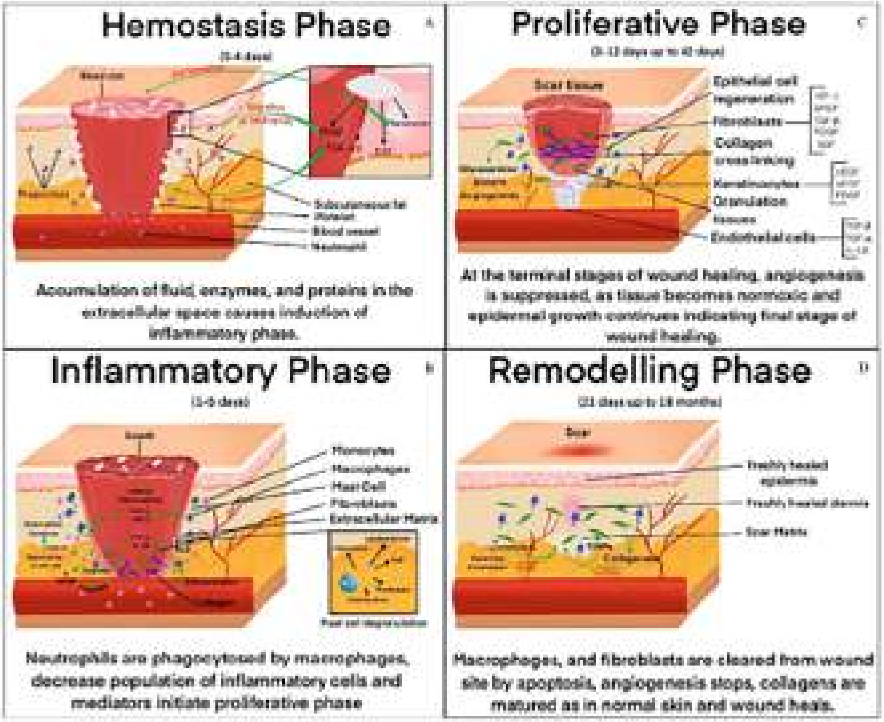

Fig. 3 Healing of wounds: pathophysiology and the mechanisms of different mediators involved. (Adapted from Khaire et al. [26]. "An Insight into the Potential Mechanism of Bioactive Phytocompounds in the Wound Management" by Manisha Khaire is licensed underCCBY4.0.) (**a**) Haemostasis phase, (**b**) inflammatory phase, (**c**) proliferative phase, and (**d**) remodelling phase. bFGF: basic fibroblast growth factor; EGF: epidermal growth factor; IGF-1: insulin-like growth factor-1; IL-1β: interleukin-1 beta; KGF: keratinocyte growth factor; MCF: monocyte chemoattractant protein; MIP: macrophage inflammatory protein; MMP: matrix metalloproteinase; PDGF: platelet-derived growth factor; NF-κB: nuclear factor kappa B; TGF-α: transforming growth factor alpha; TGF-β: transforming growth factor beta; TIMPs: inhibitors of metalloproteinases; VEGF: vascular endothelial growth factor. Haemostasis (**a**): a clot forms, creating a momentary obstacle to loss of fluid and the entrance of pathogens, which act as a storehouse for antimicrobials and bioactive substances, producing a functional extracellular matrix that supports the infiltration and movement of immunological cells, and initiating tissue healing pathway. (**b**) Inflammatory phase: An initial step that entails activating damage-associated molecular patterns, followed by the generation of free radicals, and the creation of reactive biomolecule-recruiting immune cells; then antimicrobial species are released, followed by immune cells which infiltrate and produce amplifying alarmin signals (which are intrinsic, expressed constitutively, chemotactic, and proteins/peptides that are immune activation which are released as a consequence of degranulation, cell injury or even death, or in reaction to immunological stimulation), plus keratinocyte and fibroblast activation. (**c**) Proliferation phase: this includes fibroblast, keratinocyte, and endothelial migration plus multiplication; the resolution of inflammation; extracellular matrix and collagen production, as well as a reduction in vascular permeability; the neovascularization of new lymphatic vessels and capillaries; re-epithelialization; and the new development of granular tissue. (**d**) Extracellular matrix/collagen turnover (production and breakdown); remodelling of the extracellular matrix and readjustment; contraction of the extracellular matrix; apoptosis of the fibroblast and endothelia; repigmentation [16]

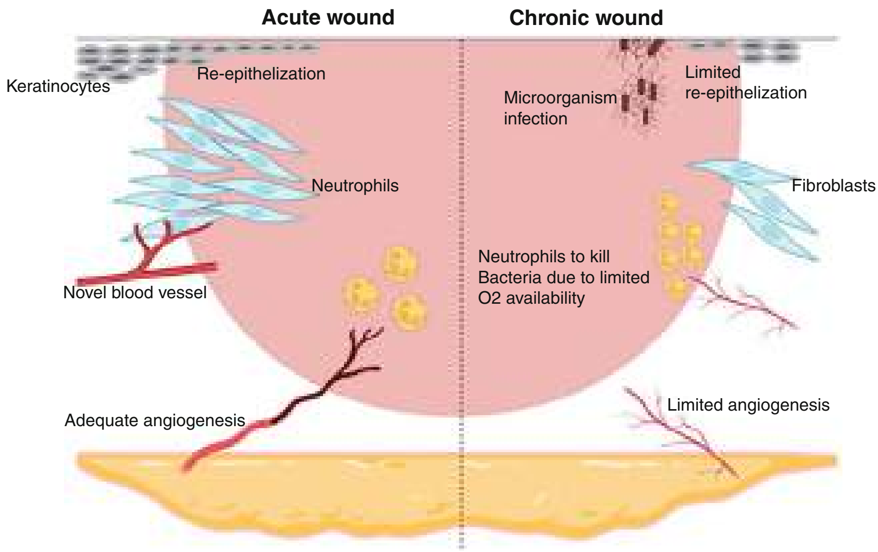

Fig. 4 Processes that are engaged in both acute and chronic wounds. Appropriate angiogenesis accompanied by re-epithelialization promotion, fibroblast propagation, and then neutrophil anti-infection activity within acute wounds (left side). Chronic wounds as seen on the right: featuring persistent local bacterial contagions, and failure of new blood vessel development. The proliferation of fibroblasts is decreased, and neutrophil anti-infection capabilities are limited by inadequate angiogenesis. (Adapted from Vitale et al. [16]. "Phytochemistry and Biological Activity of Medicinal Plants in Wound Healing: An Overview of Current Research" by Vitale et al. is licensed underCCBY4.0)

Although some wounds can be managed through simple first-aid procedures like disinfecting and dressing, others necessitate more specialized medical attention. Herbal medicine is a natural method of wound treatment that can facilitate healing while also lowering the likelihood of infection. Wounds, whether mild or serious, are common medical conditions that can benefit immensely from herbal treatment. Many herbs have been discovered to possess anti-inflammatory, antimicrobial, antioxidant, and wound-healing properties, making them effective in wound treatment. Herbs with antimicrobial properties can help decrease the chances of infection by preventing viruses, bacteria, and fungi from growing and reproducing. This is especially vital for open wounds, which can become infected. Herbs with anti-inflammatory properties can assist in reducing inflammation and swelling, enabling the body's built-in healing mechanisms to take place and so improving wound healing. Herbs with antioxidant properties help protect the body from harmful free radical and oxidative stress. Herbs with wound-healing properties can aid in the growth and renewal of healthy tissue, necessary for the repair of injured skin and tissue. In this chapter, we will look at a few of the herbs that are often used in herbal therapy to treat wounds. It is crucial to emphasize, however, that herbal medication should not be used in place of professional medical treatment.

One area where herbal medicine has been demonstrated to be particularly effective is in wound management and treatment. A diverse range of therapeutic plants and herbs are utilized in standard wound treatment, and scientists are just beginning to comprehend the phytochemical components and metabolites that give these plants their therapeutic effects.

Plants that are traditionally used for wound treatment include *Aloe vera* [7], *Calendula officinalis* [40], *Centella asiatica* [41], and turmeric [42].

6 Phytochemical Composition of Selected Plants Used in the Treatment and Management of Wounds and Infections Resulting from Wounds

Phytochemical analysis, the investigation of the chemical makeup of plants, has helped identify the specific compounds which give these plants their medicinal properties. All plants naturally produce chemical molecules as by-products of their primary metabolites carbohydrates and fats, and their supplementary metabolites, sugars, and sterols [43], which are only present in a few plant genera or species. The pigments, as well as secondary metabolites, could be converted into drugs that have therapeutic effects on people. As a result, this has led to the growth of standardized extracts and isolated compounds, which can be used, that is, wound treatment with increased safety and efficacy.

6.1 *Aloe vera*

A plant from the tropics with a wide geographic range that thrives in hot, arid climates is *Aloe vera*. The gel can be extracted from an *A. vera* leaf's mucilaginous centre. For several thousand years, the plant has been utilized and remains a key component in numerous commercial burn and skin injury care products [44]. Along with polysaccharides, enzymes, amino acids, minerals, and carbohydrates, the gel of *Aloe vera* also possesses vitamins B, A, E, and C and anthraquinone.

According to research, the glycoprotein fraction taken from *A. vera* encourages the growth and migration of cells [45].

6.2 *Calendula officinalis*

Calendula officinalis originates from the Asteraceae family and is a widely cultivated herb used for medicinal purposes in India, the United States, China, and Europe. It is known by a variety of common names, like pot marigold and marigold. *C. officinalis* has historically been applied externally to heal minor burns, other skin issues, and wounds [46, 47]. Herpes, wounds, scars, and products for the skin and hair can all be treated with *C. officinalis* infusions, tinctures, liquid extracts, creams, or ointments [48]. Chemical and pharmacological studies conducted over the past ten years have revealed that *C. officinalis* contains a vast array of additional metabolites with several pharmaceutical activities that attest to its medicinal use [16]. Triterpenoids, both esterified and free, flavonoids, quinones, carotenoids, coumarins, volatile oil, polyunsaturated fatty acids, along with amino acids, are the most active substances [40]. Studies using in vitro fibroblast and keratinocyte cells along with in vivo rodent animal models made up the majority of the studies on the roles of *C. officinalis* in the healing of acute wounds [49–52]. Most clinical research has primarily focused on chronic wounds [40], while only one clinical trial examined acute wounds [53]. In vitro, tests of calendula flower alcohol extracts (CFE) showed the presence of anti-inflammatory and anti-oedematous properties [25]. They also promoted angiogenesis in the chorioallantois membrane model, increased human keratinocyte and fibroblast migration and proliferation, and decreased collagenase activity. Transcription factor NF-kB was activated by CFE, which then affected the inflammatory stage in keratinocytes, whereas when it had a negligible impact on keratinocyte migration, it enhanced interleukin-8 chemokine levels at both the translational and transcriptional levels.

6.3 *Centella asiatica*

Centella asiatica (Gotu Kola, or Asian pennywort) is utilized to accelerate wound healing. *Centella asiatica* aerial section extracts are reported to help with healing chronic ulcers about their size, depth, and location. A punch-type wound has been demonstrated to benefit from the impact of asiaticoside, a compound isolated from *Centella asiatica*. Isolated triterpenes from *Centella asiatica* enhance glycosaminoglycan synthesis and collagen remodelling. Additionally, oral medication administration of the madecassoside in Gotu kola enhances angiogenesis and collagen synthesis at the wound site [54]. It contains several compounds like Asiatic acid, madecassoside, madecassic acid, triterpenoids, flavonoids, and asiaticoside which are responsible for its wound-healing abilities by stimulating collagen formation [41].

6.4 *Hypericum perforatum*

The herb *Hypericum perforatum*, also referred to as St. John's Wort, for millennia, has been utilized in traditional European herbal medicine and is widely distributed in Asia, Europe, and Africa [55]. It has also become naturalized in America. Because of this species' burn/wound healing and anti-inflammatory abilities, its medicinal qualities have been known since Hippocrates' time [56]. A compilation of prescriptions from a Cypriot monastery mentions the herb's use in treating cuts. Tinctures and oils from the herb are used to cure a variety of diseases, including myalgia, minor burns, bruises, abrasions, contusions, and ulcers [57]. Pharmacological research has shown that the presence of a variety of biologically active compounds is what gives *H. perforatum* its medicinal benefits. These compounds include flavonoids (quercetin, hyperoside, rutin, and quercitrin), naphtodianthrones (hypericin and pseudohypericin), xanthones (Norathyriol), prenylated acylphloroglucinols (hyperforin and hyperforin), and sesquiterpenes-rich essential oil [57]. According to research, these substances exhibit anti-inflammatory, antiseptic, antiviral, and wound-healing properties [58].

6.5 Turmeric

Turmeric, or *Curcuma longa*, a common spice, has been discovered to possess the active compound curcumin which possesses wound-healing and anti-inflammatory qualities. Since it is an active component present in the ginger family and in the *Curcuma longa* root, curcumin has been used for both medicinal and culinary purposes for many years. Ayurvedic traditional medicine practitioners utilize curcumin in treating diabetes, liver disorders, airway disorders, skin injuries, and asthma [59, 60]. Curcumin is utilized in conventional Chinese medicine as a common treatment for stomach pain. It is a widely researched nutraceutical, with frequent usage for decades by various ethnic groups. An extremely pleiotropic chemical has now been shown to correspond with important cellular pathways at the DNA replication, translation, and post-translational levels. Pro-inflammatory cytokines, adhesion cell molecules, NF-yB, apoptosis, prostaglandin E2, cyclooxygenase 2, STAT3, 5-LOX, and β-transforming growth factor, phosphorylase kinase, triglycerides, heme oxygenase-1, ET-1, AST, creatinine, and ALT which are observed in the goal pathways. Several of the helpful effects of curcumin are produced by changing the pericellular and extracellular matrix, according to experimental results from numerous in vitro and in vivo studies [21]. Therefore, it may not come as a surprise that curcumin promotes fibroblast growth, granulation tissue development, and collagen build-up during the healing of cutaneous wounds [61].

6.6 Comfrey

Comfrey is a herb that has been used for centuries to heal broken bones and wounds. It contains compounds like Allantoin, which promotes cell growth and repair.

It helps to stimulate the growth of new skin cells, which can hasten the recovery process. Rosmarinic acid has anti-inflammatory properties, Mucilage creates a protective barrier above a wound, helping to keep it moist and promoting healing, Saponins have antimicrobial properties, inulin, a polysaccharide located in the comfrey root, is considered to promote the growth of new cells and helps in healing [62], and *Symphytum officinale* is a pyrrolizidine alkaloid believed to be responsible for comfrey's capacity to heal wounds, but which has been linked to liver damage and has been banned in several countries [63]. In an experiment, comfrey leaf extract was employed to determine whether it could aid in wound healing. The topical compositions of glycerol alcohol solution, carbomer gel, and oil-in-water (O/W) emulsion were investigated. O/W emulsions have proven to be the most effective at accelerating the process of recovery. From the 3rd to the 28th day, inflammatory cell infiltration decreased from 3% to 46% while collagen deposition rose from 40% to 240%. However, the best outcomes were obtained with an 8% extract prepared as an emulsion [64].

6.7 *Echinacea*

Echinacea is a herb known for its immune system-boosting properties [65]. This was shown by its ability to stimulate the monocytes and natural killer cells, which are often deployed in innate immunity against infections [66]. This antimicrobial property makes it suitable for use to treat burns, minor cuts, and skin irritations. The plant *Echinacea* and its component chemical echinacoside look to have beneficial anti-inflammatory and tissue-healing properties [43]. Scientific research has proven the anti-hyaluronidase properties of echinacoside, an *Echinacea* coffee oil conjugate. The authors in [67] studied the significance of *Echinacea* on the hyaluronidase enzyme in pig vocal cords along with the herb's relevance in wound healing. *Echinacea* dosages of 300, 600, and 1200 mg were applied topically to the affected side at random. The findings demonstrated that anti-hyaluronidase therapy was successful in accelerating vocal cord recovery.

6.8 *Arnica montana*

Arnica montana is used topically to treat some ailments such as joint pain, bruises, wound healing, muscle aches, sprains, superficial phlebitis, insect bite swelling, and inflammation from bone breaks. Recent research indicates that it might be beneficial in treating scalds [68, 69]. Increased total phenolic acid levels in *Arnica montana* L. roots were also correlated with mycorrhization [70]. *A. montana* contains 150 therapeutically active substances, which include sesquiterpene lactones such as helenalin and 11 alpha, 13-dihydohelenalin, together with their carbonic acid ester short chains (0.1–0.5% of dry matter in leaves, 0.3–1% in flower shoots), flavonoids (0.6–1.7%) using capillary electrophoresis [71] in the form of flavonoid glucuronides, flavonoid glycosides, and flavonoid aglycones.

Other components of *A. montana* are arnidiol; carotenoids; diterpenes; coumarins (umbelliferone and scopoletin); polyacetylenes; pyrrolizidine alkaloids (tussilagine and isotussilagine) [72]; phenolic acids (Heriguard, limonin, 1.0–2.2%) and caffeic acid [26]; dicaffeoyl quinic acid (DCQA) derivatives (cynarin, ZINC13451209, and 4,5 dicaffeoyl quinic acid); oligosaccharides; and lignans [73]. It consists of sesquiterpene lactone derivatives like tigloyl, methacryloyl, metacryl, isobutyryl, and isovaleryl helenalin [74]. The composition and quantity of phytochemicals such as helenalin esters, phenolics, caffeic acid derivatives, and dihydrohelenalin esters which exist in the flower shoots are different, depending on climate and latitudinal variations, according to a phytobiological study of *A. montana.* Several researchers have discovered that the plant's flowers are mostly rich in active components [73, 74]. Sesquiterpene lactone quantity and nature vary with latitude. Flowers gathered from high-latitude grasslands primarily possess helenalin esters, whereas flowers collected from lower-latitude pastures primarily contain dihydrohelenalin esters. Another study looked at the significance of environmental conditions on the degree of xanthotoxin lactones in 10 German grasslands. Xanthotoxin lactone concentration was higher (0.59–1.10%) [75].

6.9 Chickweed

Chickweed or *Stellaria media* Linn. is a herb that has already been traditionally utilized in treating skin irritations and wounds. It contains compounds that can decrease inflammation and promote cell growth [76]. Chickweed has a high concentration of lipids [77], triterpenoid [78], C-glycosyl flavonoids [79], phenolic compounds and flavonoids [76], sitosterol, phlobatannins, pentasaccharide and alkaloids [80], and saponins [81]. Furthermore, (S)-2-aminohexanedioic acid, 6,7 dimethylheptacosane, oxalic acid, 5-acetoxydotetracont-3-en-1-ol, saponarin, and saccharopine are bioactive metabolites identified from chickweed aerial parts [82]. Another phytochemical investigation discovered active biological metabolites in several regions of chickweed and its preparations [76]. Flavonoids are mostly saponarin, apigenin 6-C-glucoside (isovitexin), apigenin glucoside arabinoside, isovitexin 7,2-di-O-glucoside, isovitexin 7-O-galactosyl-2-O-glucoside, apigenin 6-C-α- apigenin 6-C-β-D- galactosyl-8-C-β-L-arabinoside, quercetin 3-O-rutinoside (rutin), apigenin 6,8-di-C-α- L-arabinoside, L-arabinosyl-8-C-β-D-galactoside, apigenin 6-C-β-D-glycosyl-8-C-β-D- galactoside, coumarins, likewise ascorbic acid [83]. Luteolin, kaempferol, quercetin, rutin, sinapic acid, protocatechuic acid, vanillic acid, catechin hydrate, and resorcylic acid are phenolic chemicals found in chickweed leaf extracts [84]. Other chemicals extracted through the aerial section of the chickweed include 6-methylheptyl-3′-hydroxy-2′-methylpropanoate, 2, 2, 4-trimethyloctan-3-one and 2, 4, 5, 7-tetramethyloctane [76]. These vital metabolites exhibit anti-inflammatory properties and aid in weight loss [85].

Hydroxycinnamic acids, catechins [86], saponosides, ascorbic acid, mucilage, polyphenols, silicon, and carotene are important antioxidant active components [87]. Chickweed possesses a high concentration of phenolic acid, flavonoids, phlobatannins, alkaloids, tocopherol, and Vitamin C, all of which play important antioxidant roles in the human body [76].

6.10 Lavender

Lavender is a herb that has been traditionally utilized in treating minor cuts, scalds, and other derma irritations. It has antiseptic and anti-inflammatory properties, which can assist in lowering the risk of infection and promote healing [88]. Before flowering, lavender flowers (*Lavandulae flos*) are gathered to make the medicinal raw material. Lavender's principal biologically active agents are phenolic compounds, triterpenes, essential oil components, and sterols [89]. Lavender is mostly recognized for its essential oil, which is available in concentrations ranging from 2% to 3% [43]. By steam distillation or hydrodistillation, it is extracted from the petals. Linalyl acetate and linalool are the essential oil's two main components, with concentrations ranging from 1.2% to 59.4% and 9.3% to 68.8% respectively [43]. Both the high concentration of linalyl acetate and linalool and their relative proportions affect the quality of lavender essential oil [90]. Terpenes such as limonene, borneol, eucalyptol, camphene, camphor, −ocimene, 1,8-cineol, fenchone, acetate, α-terpineol, lavandulol, β-caryophyllene, α-pinen and geraniol, and also non-isoprenoid cyclic components such as octenol, octanon, octanol, and octenyl acetate are the major chemicals [89]. Polyphenols are another significant class of chemical elements found in lavender flowers. These are plant secondary metabolites that possess diverse biological characteristics. Flowers, leaves, stalks, fruits, and seeds are just a few of the plant's components where they are found [91]. Almost 8000 polyphenolic chemicals have so far been discovered [92]. They are identified through single or multiple cyclic rings and various numbers of hydroxy groups in a molecule about chemical structure [93]. The shikimate pathway is used in the biosynthesis of polyphenols [94]. They could be separated into numerous different classes, including lignans, coumarins, stilbenes, flavonoids, and phenolic acids [94]. The majority of phenol compounds are discovered in mixtures with organic acids, sugars, and esters [93]. The hydroxybenzoic acid derivatives and the 3-coumaric acid derivatives are the two categories of phenolic acids [95]. The most prevalent hydroxycinnamic acid in the *Lavandula* genus is rosmarinic acid [96]. The principal participants in this group are 3-hydroxybenzoic acid, benzoic acid, syringic acid, 4-hydroxybenzoic acid, vanillic acid, gallic acid, protocatechuic acid, homovanillic acid, and homoprotocatechuic acid [97]. The research of [98] in a rat model showed that topical lavender oil treatment dramatically improved the synthesis of collagen by fibroblasts, which was associated with elevated TGF- β expression in wound abrasions and increases the production of granulation tissue by synthesizing collagen, tissue remodelling by switching from type III to type I collagen, and wound shrinking.

6.11 *Panax ginseng*

This is a popular medicinal plant in Japan, China, Eastern Siberia, and Korea [21]. Recollection is also thought to boost immunity, improve physical agility, and lessen weariness [21]. Hence, the herb is utilized in treating anxiety, chronic fatigue syndrome (CFS), and depression. It has been demonstrated that *Panax ginseng* has vasodilatory, blood lipid-controlling, anticancer, anti-inflammatory, antibacterial, anti-allergic, anti-ageing, and immunomodulatory properties [99]. Several bioactive compounds make up *Panax ginseng*, but a type of saponin is its most effective active component (also known as ginsenosides by Asian scientists and panaxosides by Russian researchers) [21]. Preparations of the root of *Panax ginseng* are attested to shield the skin from severe UVB rays and significantly accelerate the healing process after laser burns and excision wound damage [21]. According to studies, *Panax ginseng* extracts boost human dermal fibroblasts' ability to proliferate, promote keratinocyte migration, and produce collagen ex vivo. However, ginsenoside Rb2, which is separated from *Panax ginseng*, has been revealed to stimulate the growth of the epidermis in raft kelp culture by boosting fibronectin and the receptor, epidermal growth factor, and receptor expression, as well as collagenase I and keratin, which are all essential/critical for wound healing [100]. According to Park and Park [101], *Panax ginseng* may promote the repair of full-thickness skin lesions and also has a great effect on skin regeneration, suggesting its usage as a wound dressing and development as a food product.

6.12 Neem

Neem (*Azadirachta indica*) is renowned for its antifungal, anti-ulcer, anticancer, antiviral, antibacterial, and antioxidant properties in wound dressing. The anti-oxidation of nitric oxide in RAW 264.7 cell lines was evaluated by [102]. Inside wells coated with integrated collagen and 1000 g/mL of *Azadirachta indica* extract, the nitric oxide level was determined to be 10 g/mL. The biocomposite film possesses effective nitric oxide antioxidant and anti-inflammatory properties. In additional studies, the scientists used the *Azadirachta indica* -incorporated collagen film cell lines to perform the antioxidant activities and the biocompatibility test. The combined collagen films of its extract (400 g/mL) demonstrated an 80% improvement in DPPH scavenging ability and had at least 80% cell viability using the MTT assay. Research shows that the herb contains azadirone, azadirachtin, nimbin, nimbidin, and nimbinin [103].

6.13 German Chamomile (*Chamomilla recutita*)

For German chamomile, scientists investigated the effectiveness of PCL/PS electrospinning nanofiber membranes as active wound dressings that contain chamomile. Quercetin, apigenin, luteolin, patuletin, and their glucosides are some of the specific phenolics and flavonoids that provide the Asteraceae plant, C. *recutita* (L.) Rauschert, its therapeutic properties [21]. The most uncommon flavonoid discovered in chamomile plants, apigenin, has a notable impact on how quickly wounds heal [104].

Nanofibers were demonstrated to be efficient against microorganisms, *C. albicans* (fungi) and *S. aureus*, showing inhibitory zones measuring around 7.6 mm in width, according to studies of antifungal and antibacterial in vitro [104]. The mesenchymal stem cells' survival and ex vivo cell adherence to the nanofibers were demonstrated by the MTT assay. The authors' research revealed that the nanofibers, mixed with about 15% of *Chamomilla recutita* extract, could cure a large proportion of the injury 14 days following therapy, which was verified using a rat injury model. This injury evaluation revealed that collagen accumulated in the tissue's dermis together with re-epithelization as well as the absence of necrosis [104] (Table 1 and Fig. 5).

7 Conclusion

This review is a significant addition to natural product research and wound therapy. As such, it has the potential to influence both research and development and clinical treatment in this field. Going forward, the outcomes of this review could be utilized to direct future studies into the individual phytochemicals and metabolites that are most beneficial in wound treatment and management. This might facilitate the invention of novel chemicals with wound-healing characteristics, which could then be turned into new patient medicines. Furthermore, the study could have practical implications for the use of herbal medicine in wound treatment. Clinicians and patients could benefit from a more evidence-based approach to selecting herbal treatments for the care of wounds if specific plants and metabolites that are beneficial in treating wounds are defined. Overall, the literature evaluation has the potential to assist and guide future research and clinical practice in natural products research and wound healing.

The evaluation of phytochemical components and metabolites in medicinal plants and herbal medicine used in wound therapy and management is an important area of research. Traditional medicine usage for wound healing has been applied for centuries and continues to be significant in modern times. Many medicinal plants contain phytochemicals such as phenolic compounds, flavonoids, terpenoids, and alkaloids, which have been demonstrated to have wound-healing properties. Furthermore, by the growing need for natural and safe alternatives to traditional therapy, using herbal medicine to treat wounds has attracted increased attention in recent times. The assessment of phytochemical elements and metabolites in medicinal plants used for wound remedy has shown encouraging results, and the discovery of active chemicals in these plants may lead to the development of novel and effective wound-healing medications.

Finally, the evaluation of phytochemical components and metabolites in herbal medicine and medicinal plants used in the treatment and management of wounds has the potential to provide a better understanding of these plants' modes of action, in addition to helping to create novel and effective wound treatments.

Table 1 Plants and their constituents used in wound repair

Scientific name	Common name	Plant part and formulation	Phytochemical compositions	Biological function	Mechanism of action	References
Aloe vera* (L.) *Burm. f. anagallis	Aloe	Corpulent leaves, gel	Flavonoids- (aleosin, aloin, rhein, emodin) Polysaccharides- (glucomannan, acemannan, and acetylated polymannan)	Antibacterial, anti-inflammatory, epithelialization process	Regulates inflammatory response; regulates the autophosphorylation of signalling proteins; enhances collagen deposition and angiogenesis; boosts the propagation of fibroblasts and mildly stimulates the migration of keratinocytes.	[105–107]
Calendula officinalis	Pot marigold	Flowers	Triterpenoids, Flavonoids- (5-O-caffeoylquinic acid, caffeic acid, isorhamnetin-isorhamnetin-3-O-rutinoside, rosmarinic acid, medicocarpin, nicotiflorin, venoruton, and isoquercetin) Quinones – coumarins	Re-epithelialization process, anti-inflammatory	Increases the appearance of inflammatory mediators; enhances keratinocyte and fibroblast proliferation; boosts collagen biosynthesis and angiogenesis; suppresses lipoxygenase activity; decreases glutathione levels.	[26, 52, 108, 109]
Centella asiatica	Gotu kola	Leaf	Triterpenoids/ triterpenes Flavonoids (Asiatic acid, madecassoside, madecassic acid, and asiaticoside	Antioxidant, antimicrobial, anti-inflammatory, neuroprotective, and wound healing	Collagen depositing and re-epithelialization in a punch-type wound Collagen repair and biosynthesis of glycosaminoglycans Synthesis of collagen and angiogenesis at the wound site	[110, 111]
Hypericum perforatum	St. John's wort	Flower	Hyperforin, hyperoside, hypericin, quercetin,	Antioxidant, antiatherogenic activity, antidepressant, oestrogen-	Inhibition of lipoxygenase activity and prostaglandin E reduction; shorten the interval of	[112–115]

(continued)

Table 1 (continued)

Scientific name	Common name	Plant part and formulation	Phytochemical compositions	Biological function	Mechanism of action	References
			flavonoids, tannins, and saponins	mimetic activity anti-inflammatory, analgesic, gastroprotective	inflammation, stop fibroblast migration during the process of wound healing	
Curcuma longa	Turmeric	Rhizomes	Diarylheptanoids/ curcuminoids Curcumin, demethoxycurcumin, bisdemethoxycurcumin, 5′-methoxycurcumin, dihydrocurcumin, Sesquiterpenes turmerone, zingiberene, arturmerone, fatty acids, sesquiterpenoids, monoterpenoids, proteins	Antioxidant, gastroprotective, anti-inflammatory, antiseptic, antibacterial, antimicrobial, antimutagenic, anticancer, antifungal, hepatoprotective, cardioprotective, hypoglycaemic, antiarthritic, antidepressant	Prevent local activation and appearance of NF-κB genes which mediate joint inflammation and destruction, reduce histamine production and prolong the impact of cortisol against inflammation, reduce in 9,2-benzanthrazen-induced DNA adducts and consequent reduction of carcinogenesis; granulation and tissue formation, increase fibroblast migration, increase TGF-β production; collagen deposition; increase fibroblast proliferation; inhibition of membrane phospholipid peroxidation and surge in liver lipid metabolism; inhibition of the increase in thiobarbituric acid-reactive substance and protein carbonyl and reversing changed activities of antioxidant enzymes	[25, 116–121]
***Symphytum officinale* L.**	Comfrey	Leaves	Tannins, terpenoids, triterpenoids, amino acids,	Anti-inflammatory, analgesic, antioxidant,	Decreasing inflammation, apoptosis, and oxidant stress,	[122–126]

			flavonoids, reducing agents, flavones, saponins, alkaloids, allantoin, polysaccharides, phenolic acids (caffeic, rosmarinic, and caffeoylquinic acids), glycosides, pyrrolizidine phytosterols, and triterpene saponins	antitumour, antiapoptotic, neuroprotective, antibacterial, hepatoprotective, antihistamine	through the NF-kB, Nrf2, and caspase-3 pathways; correcting cholinergic disorders, correcting the antioxidant-oxidative imbalance, delaying the occurrence of the pro-inflammatory event in primary human epithelial tissue	
Echinacea	Purple coneflower	Roots, flowers, leaves	Phenolics – echinacoside, caftaric acid, chlorogenic acid and cichoric acids (CADs), cynarin Alkylamides – polysaccharides/ glycoproteins Arabinogalactans	Antioxidant, antibacterial, anxiolytic, anti-inflammatory, anti-hyaluronidase, analgesic, tissue healing, antimicrobial, antifungal, cyclooxygenase, and lipoxygenase enzyme activities, immunostimulant, vitamin C	Stimulate phagocytosis, T-cell production, lymphocytic activity, cellular respiration (anti-oxidation) action against tumour cells, inhibit hyaluronidase enzyme secretion	[127–131]
Arnica montana	Mountain tobacco	Flowers	Sesquiterpene Flavonoids – flavonoid glucuronides, flavonoid glycosides, and flavonoid aglycones Lactones – Helenalin,11a,13-dihydohelenalin Essential oils – monoterpenes, fatty acids, thymol derivatives, and sesquiterpene; carotenoids;	Antiphlogistic, inotropic, anti-inflammatory, antibiotic, uterotonic, immunomodulatory, antiplatelet, analgesic and anti-rheumatic, antibacterial, antifungal, antioxidant	Increase blood circulation to the affected area, which can improve the delivery of nutrients and oxygen to the injury site, aiding in the healing process; reduce inflammation, stimulate the immune system, promote tissue regeneration, and scale down development of scar tissue	[71, 73, 74, 132]

Abstract

Osteoarthritis (OA), characterized by degeneration of the joints, is forecast to be the major cause of disability for older people by 2030. The primary pathology of osteoarthritis are cartilage and bone rebuilding. Osteoarthritis management consists of pharmacotherapy, physiotherapy, and surgery. OA should traditionally be treated using herbal medications in various medical systems around the world in addition to steroid use. These provide symptomatic relief from pain and inflammation, but minimally reduce joint destruction. Structural damage needs to be effectively prevented and should be the main goal of new therapeutic regimens. Phytoconstituents especially belonging to phenolics, flavonoids, steroids, terpenoids, sterols, sesquiterpenes, triterpenes, and phytoalexins class exhibit antioxidant, anti-inflammatory, anti-arthritic effects and prove beneficial in OA. These phytochemicals modulate different targets like cyclooxygenases, lipoxygenases, and other signaling pathways involved in the pathophysiology of OA, thereby providing immense benefits. These also serve as potential leads for the development of new chemical entities as potential anti-inflammatory molecules of diverse utility. A number of clinical trials have found that herbal remedies and their components are essential to mitigate osteoarthritis. Reflex plus™ is a patented combination of collagen hydrolysate and rosehip extract. Ingredients in the blend have been thoroughly researched for their efficacy in arthritis. Collagen hydrolysate tends to accumulate within cartilage and assists in repairing the damage caused by osteoarthritis and other cartilage alterations. The rose hip works on the anti-inflammatory pathway to reduce joint discomfort and inflammation. The most important pro-inflammatory cytokines implicated in the pathogenesis of osteoarthritis are TNF-α and IL-1β, which act on synoviocytes and chondrocytes by specific interactions with cytokine receptors at the cell surface, assisting in the construction of cartilage for the effective functioning of the joints and the relief of pain associated with osteoarthritis and also help in the protection of cartilage. The purpose of this chapter is to incorporate the impact of phytochemicals on various molecular targets of inflammation into the overall management of osteoarthritis.

Keywords

Osteoarthritis · Anti-inflammatory · Herbal medicine · Phytochemicals · Rose hip

Abbreviations

BMD	Bone mineral density
CH	Collagen hydrolysate
COX-1	Cyclooxygenase -1
COX-2	Cyclooxygenase -2
FDA	Food and Drug Administration

Fib3-1	Fibrin-3-1
Fib3-2	Fibrin-3-2
FSTL1	Fibulin-3 peptide and follistatin-like protein-1
GMPs	Good Manufacturing Practices
GOPO	Galactolipid
GS	Glucosamine sulfate
IL-1	Interleukin-1
IL-6	Interleukin-6
IL-8	Interleukin-8
LDL	Low-density lipoproteins
MMP-13	Matrix metalloproteinase-13
NSAIDs	Non-steroidal anti-inflammatory drugs
OA	Osteoarthritis
PMN	Polymorphonuclear
PUFAs	Polyunsaturated fatty acids
RONS	Reactive oxygen and nitrogen species
ROS	Reactive oxygen species
TNF- α	Tumor necrosis factor alpha

UV-B	Ultraviolet B

1 Introduction

Osteoarthritis (OA) is the most prevalent joint disease. It is the most common type of arthritis, with a higher chance of reduced mobility (defined as assistance in walking or climbing stairs) in individuals over 65 years old who have affected knees [1]. OA is a multifactorial condition with disparities in structure and function throughout the joint. The changes that occur in articular cartilage as a result of aging can lead to the degeneration of tissue and a pathological process characterized by a gradual and typically progressive deterioration of tissue structure and function [2]. In a typical knee joint, the cartilage remains intact and undamaged, preserving the joint's health and functionality. Similarly, the meniscus, a crucial component for shock absorption and stability, remains healthy and fully functional. There are no signs of osteophytes, which are bony outgrowths that can affect joint movement [3]. Moreover, the subchondral bone and ligaments exhibit no abnormalities, maintaining their normal state. Conversely, in a knee joint affected by osteoarthritis, there is a breakdown of the cartilage, leading to compromised joint integrity. The meniscus also suffers damage, reducing its ability to effectively cushion and stabilize the joint [4]. Osteophytes, which are indicators of degeneration, become present, potentially hindering smooth joint movement. Additionally, the subchondral bone undergoes remodeling and sclerosis, contributing to the altered joint structure. Ligaments may also be affected by these changes (Table 1). All the diseases associated with aging, osteoarthritis is perhaps the most strongly correlated and causes significant mobility impairment. The aging process results in significant changes to the structure, composition of the matrix, and mechanical properties of articular cartilage. Most

Table 1 Difference in normal knee and osteoarthritis knee

Normal knee	Osteoarthritis knee
No cartilage damage	Cartilage breaking down
Healthy meniscus	Damaged meniscal
No osteophytes	Presence of osteophytes
Normal subchondral bone and ligaments	Bone remodeling and sclerosis

individuals with fibrillation of the articular surface do not suffer from joint pain or dysfunction. Therefore, the age-related fibrillation of articular cartilage does not necessarily lead to the progressive degeneration of articular cartilage that results in osteoarthritis [5, 6].

Pain and stiffness in the affected joints are the most common signs of osteoarthritis. Discomfort usually intensifies when the joint is moved or toward the end of the day. Joints may become stiff after a period of rest, but this typically subsides relatively quickly once movement resumes. Symptoms of the condition often fluctuate without any obvious cause, with periods of discomfort lasting for several weeks or months, followed by periods of relief. On occasion, the affected joint may become swollen. Swelling in the joints, particularly in the fingers, can take on a knobby and hardened appearance due to the formation of additional bone tissue, or a soft and puffy appearance caused by the thickening of the joint lining and the accumulation of extra fluid in the joint capsule (Fig. 1).

The joint may produce grinding or crackling noises during regular movement, which is known as crepitation. At times, the muscles around the joint may appear weak or atrophied. Engaging in exercises that strengthen the muscles supporting the joints can prevent this from happening [7]. The exact cause of osteoarthritis remains uncertain. It is more than just a result of regular "wear and tear," and the likelihood of developing osteoarthritis is influenced by various factors [8], such as:

1. Age: Osteoarthritis typically emerges in the late forties, possibly due to age-related bodily changes like muscle weakness, weight gain, and reduced efficiency in the body's healing ability.
2. Gender: Osteoarthritis is typically more prevalent and severe in women in most joints.
3. Obesity: Being overweight, particularly in weight-bearing joints like the hip and knee, is a common cause of osteoarthritis [9].
4. Joint Injury: Arthritis can develop in a joint later in life due to a severe injury or surgery. Osteoarthritis is not caused by regular activity or exercise; however, the risk may increase with very strenuous or repetitive activities or physically demanding occupations.
5. Abnormalities in the joints: If person were born with abnormalities, OA may begin early and be more severe than usual [10].
6. Weather and Diet: Several individuals with osteoarthritis may notice that changes in weather worsen their pain, especially when the atmospheric pressure drops before it rains. However, weather changes do not cause osteoarthritis; they can

Fig. 1 Normal and osteoarthritis knee

only influence the symptoms. However, your risk of developing osteoarthritis is influenced by your weight somewhat than other specific dietary factors [11].

Accurate diagnosis of arthritis is fundamental to its treatment. There are numerous types of arthritis, and each may require different treatments. Typically, diagnosing osteoarthritis involves evaluating an individual's symptoms, medical history, the progression of their symptoms, and the physical examination of the affected joint [12]. Osteoarthritis impacts various joints across the body, leading to discomfort and reduced mobility. The affected joints encompass the neck, shoulders, lower back, hips, elbows, base of the thumbs, fingertips, knees, ankles, and the base of the toes. In these areas, the cartilage gradually deteriorates, causing pain, stiffness, and limited joint movement [13]. Osteoarthritis commonly targets these regions, contributing to challenges in daily activities and prompting the need for management strategies to alleviate its effects. Physical examination of joints involves screening for tenderness over the joint, Crepitus, also known as joint grating or creaking, bone swelling, excessive fluid, difficulty in movement, instability of joint, weakness of muscles or thinness that supports the joint.

Blood tests such as CBC, ESR, and rheumatoid factor are usually normal in OA. X-rays may not always be useful in diagnosing osteoarthritis or determining the appropriate treatment options. However, they can detect the presence of calcium deposits in the affected joint.

In rare cases, an MRI scan of the knee may prove to be useful. High-frequency radio waves can also be used to create images of soft tissue and bone changes that would not be evident on an X-ray. Its primary function is to uncover other potential joint and bone abnormalities that may be causing the symptoms [14].

2 Pathophysiology of OA

OA is deemed an organ disease that affects all joint structures. Subchondral osteosclerosis, articular marginal osteophytes, and moderate, chronic, nonspecific synovial inflammation are all associated with progressive loss of articular cartilage in synovial joints [15, 16].

2.1 Articular Cartilage

Despite the involvement of multiple joint tissues, osteoarthritis has long been characterized mainly by interruption of the repair method in damaged cartilage as a consequence of biochemical and biomechanical changes in the joint. The normal maintenance of physiological homeostasis in articular cartilage is controlled by chondrocytes, which generate a structural matrix consisting mainly of type II collagen and proteoglycans [17]. Chondrocytes can produce less effective collagen (type I collagen), smaller and less dense proteoglycans, more degradable enzymes, and nitric oxide, which produces different inflammatory mediators, including IL-1, when subjected to mechanical stress and interleukin (IL)-1. The imbalance between breakdown and synthesis of the extracellular matrix leads to a vicious cycle, resulting in the loss of articular cartilage. This process does not cause clinical symptoms until the innervated tissue is affected, as articular cartilage is avascular [18].

2.2 Osteophytes

Osteophytes near the end of the joint can expand at this point. Osteophytes are cartilage-covered bony growths. Osteophytes are classified into three types: traction spines, where ligaments and tendons adhere to bone, inflammatory spines from vertebral bodies, and osteochondrocytes, which generate cartilage by synovial metaplasia. They can cause discomfort in spinal osteoarthritis but are advantageous in lower extremity osteoarthritis because they support the joints [19, 20].

2.3 Synovial Inflammation

The synovial membrane is essential for appropriate functioning of joints by providing nourishment to chondrocytes via synovial fluid and joint space, as well as removing waste products and breakdown products from the matrix. Synovial mucosal cells produce hyaluronic acid and lubricin, which help to protect and maintain articular cartilage [21]. In osteoarthritis, synovial inflammation contributes to various clinical symptoms, such as pain, and correlates with the progression of the disease. In addition, synovitis is a main element in the pathophysiology of osteoarthritis through the action of several soluble mediators. The association between arthroscopically assessed synovitis and the fraction of functional impairment or pain insights continues to be debatable [22].

3 Molecular Targets of OA

Cytokines, proteinases, lipid mediators, and reactive oxygen species stimulate chondrocytes to produce enzymes that break down cartilage. In patients with osteoarthritis, levels of IL-6, IL-8, and MMP-13 are significantly higher in osteophyte-derived osteoblasts [23]. The expression of IL-6 and IL-8 genes in osteoblasts was found to increase in response to non-physical mechanical stress, and the degree of stress was found to be directly proportional to the magnitude of this increase. This suggests that inflammatory factors play an even greater role in the formation of osteophytes.

Furthermore, IL-6 stimulates the production and expression of MMP-13 in osteoblasts derived from osteophytes and those located in the subchondral region affected by osteoarthritis. Increased IL-8 and MMP-13 expression can cause cartilage degradation through chondrocyte enlargement [24]. Growth factors, which are responsible for the synthesis of the normal matrix, including insulin-like growth factor-1, bone morphogenetic protein, platelet-derived growth factor, and transforming growth factor, play a crucial role in inhibiting the activity of pro-inflammatory cytokines and supporting repair. Osteoarthritis can cause cartilage damage. They enhance anabolic activity and proteoglycan production in chondrocytes while inhibiting catabolic activity [25].

Currently, there are no biomarkers that can be considered reliable tools for diagnosing and predicting the progression of osteoarthritis in routine clinical practice. Fibulin-3 peptide and follistatin-like protein-1 (FSTL1), on the other hand, are extracellular proteins with promise as osteoarthritis biomarkers. Fibrin-3 is frequently distributed in several kinds of tissues and blood vessels of different sizes, and can prevent vascular encroachment and angiogenesis [26]. In addition, it also improves the cartilage in osteoarthritis. An osteoarthritis patient's urine and serum have a larger proportion of their two fibrin-3 fragments (Fib3-1 and Fib3-2) than controls. Increased levels of Fib3-1 were found to be associated with aging and hormone levels, while Fib3-2 levels were not related to gender, age, or menopause. FSTL1, which is activated by ischemic stress and inflammatory mediators, is expressed in human tissues. It is important to note that this information is paraphrased and not intended to be used as medical advice. Serum FSTL1 levels have been found to correlate with inflammatory status, making it a potential biomarker for rheumatoid arthritis and other autoimmune diseases. FSTL1 is thought to play a role in the etiology of arthritis and is activated by ischemic stress and inflammatory mediators in human tissues. The levels of serum FSTL1 were significantly higher in patients with osteoarthritis than in healthy individuals, and in women, they were correlated with the severity of the disease and the expansion of joint space [27].

4 Management of OA

Although there is still no cure for osteoarthritis, there are treatments that can relieve symptoms shown in Fig. 2. These include: 1. Changes in lifestyle, such as increased physical activity, muscle-building exercise, and weight loss (where relevant); 2. Painkillers, e.g., pain-relieving creams or gels or steroid injections; 3. Physical therapies, e.g., application of heat, splints, or other aids; 4. Surgery; 5. Complementary treatment and supplements [28].

4.1 Physical Activity

Many patients are concerned that exercising would aggravate their discomfort and create further joint injury. Physical activity can help protect your joints by strengthening the muscles that support them, as well as control pain, relieve stress, and decrease excess weight. If the discomfort makes it difficult to move, take a pain medication like acetaminophen and warm up the bothersome joint beforehand, or apply an ice pack [29]. There are three types of workouts:

Movement exercises: Exercises that involve movement are beneficial to posture, strength, and flexibility. The exercises softly and gently loosen up the joints to a range of motion that feels pleasant to the touch [30]. This coupled with low intake and low serum levels of vitamin D are linked to increased risk of OA progression [31].

Strengthening workouts: These are exercises that use water, light weights, or resistance bands to provide resistance and strengthen the muscles that support and move your joints. Because of a natural dread of pain, many individuals become less

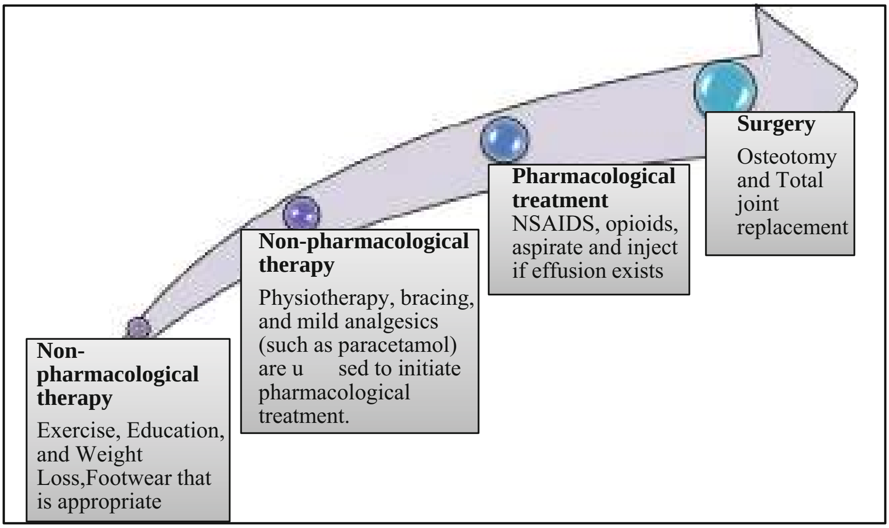

Fig. 2 Management approaches of osteoarthritis

active when they get arthritis, which can lead to increased damage causing muscles to weaken that can cause muscles to weaken and even become noticeably thinner, making it even more difficult for joints to function normally to retain [32].

Aerobic exercise: For individuals experiencing joint pain, walking, cycling, and swimming are all great forms of exercise. You could also consider using a stationary bike or elliptical machine. Walking in the shallow end of a pool is an effective way to improve leg muscle strength. Pools designed for hydrotherapy or aquatic therapy are typically warmer than regular swimming pools. Water provides a comforting and pain-relieving effect, and the buoyancy helps in weight support, making it easier to perform some stretching exercises while waiting for daily activities like cooking or doing household chores [33, 34].

Weight loss: Even a small reduction in weight can have a significant impact on symptoms, particularly for those who are overweight. A well-balanced diet is the most effective way to achieve weight loss. To reduce calorie intake, one should avoid consuming foods that are high in fat and sugar. At the same time, it's important to have a balanced diet that includes all major food groups. Gradual increment in physical activity can also assist with weight loss. There are various ideas regarding what is good and harmful to eat when you have arthritis, but no single diet has been shown to assist. Consulting with a nutritionist is recommended to determine the most appropriate dietary plan. Some studies suggest that including fatty fish or fish-derived oils in the diet may be beneficial in alleviating symptoms of certain types of arthritis [35, 36].

4.2 Medication

The medications that are broadly taken for OA do not influence the actual condition. However, they can help reduce the side effects of inflammation and tension. NSAID gels and creams: Topical creams, gels, and patches containing nonsteroidal anti-inflammatory drugs (NSAIDs) can be applied directly to the skin for pain relief. Drug stores and stores sell ibuprofen and diclofenac gels over the counter. Others, such as ketoprofen, are only available with a doctor's prescription [37]. Creams, gels, and fixes can be effective for specific joints, most notably the knees and hands, but they cannot treat joints that are deeper under the skin, such as the ankles and hips. They are quite safe and are typically used as the first line of defense in drug therapy [38, 39].

Capsaicin cream: Capsaicin cream is a powerful pain reliever derived from the pepper plant (capsicum). It is very beneficial for knee and hand osteoarthritis, as are NSAID creams and gels. It should be used on a daily basis. When most people first take capsaicin, they feel a heat or burning sensation, which usually goes away within a few days. Capsaicin is extremely safe, just like NSAID creams, gels, or fixes [40, 41].

Paracetamol: The safest form of pain treatment to attempt first is paracetamol. It is best to take them before the pain becomes unbearable. Spending extra money on expensive paracetamol brands, which can be obtained without a prescription at drugstores and supermarkets, does not provide any advantages [42, 43].

Nonsteroidal anti-inflammatory drugs (NSAIDs): Nonsteroidal anti-inflammatory drugs (NSAIDs) are a more effective pain relief option compared to acetaminophen. Ibuprofen is the most commonly used NSAID and can be purchased in low to medium doses at pharmacies and supermarkets. If necessary, the doctor may advise high doses of ibuprofen, such as naproxen or diclofenac. Celecoxib and Etoricoxib, two newer forms of NSAIDs, are said to reduce the incidence of stomach ulcers and discharges [44, 45].

Steroid injections: Long-acting steroid injections are occasionally delivered straight into a sore joint. The injection usually begins to work within a day or two and can relieve pain for several weeks or even months, particularly in the knee or thumb. Steroid injections are frequently utilized for managing painful osteoarthritis or abrupt, intense pain triggered by crystals in the joint. The doctor may also provide a steroid injection if the arthritis could interfere with an important event [46, 47].

4.3 Physical Therapies

Heat and cold: Heat applied to a painful joint might help ease pain. To prevent skin damage, use a hot water bottle covered in a towel or a microwaveable wheat bag. Another option is to soak your hands or feet in a bowl of warm water for a short period. In case of joint inflammation, an ice pack covered in a towel can help relieve swelling and discomfort. Apply ice for up to 20 minutes every few hours [48].

Splints and other supports: Orthoses, braces, and other supports are available to assist with problematic joints. When osteoarthritis has changed the orientation of a joint, these can be incredibly helpful. It is best to seek expert counsel from a competent specialist or physiotherapist before making your decision [49, 50].

Shoes: Choosing comfortable, durable shoes influences not just your feet, but also your knees, hips, and spine. The perfect shoe would have a thick but delicate bottom, a delicate upper, and plenty of space at the toe and arch. To relieve pressure on areas of the foot not affected by osteoarthritis, the doctor or podiatrist may offer orthotics for various foot problems [51, 52].

Crutches: Some people use a cane. Holding it in the other hand can also mitigate knee or hip pain. It is best to obtain the counsel of a knowledgeable medical professional because your reasons for utilizing a stick will dictate which side it should be used on. It is crucial that a walking stick is adjusted properly according to the body size, a good provider should do this. Check that the handle feels comfortable in the hand if there is arthritis in the hands [53, 54].

Posture: Posture affects joint alignment, among other things. This in turn can lead to joints or joint parts being subjected to greater stress than usual [55].

4.4 Surgery

The majority of patients with osteoarthritis do not require surgery. However, if the arthritis is severe and the symptoms have a significant influence on quality of life, the doctor may recommend surgery. Every year, thousands of hip and knee replacement procedures are performed for osteoarthritis, and other joint replacement surgeries are becoming more popular [56]. There are additional surgical options than joint replacement. Washing out loose bone fragments and other tissue from the knee can sometimes be accomplished using keyhole surgery. This is known as arthroscopic lavage. Fusion can be quite effective for some tiny joints. This means that the bones in a joint are surgically fixed, preventing movement and, as a result, pain. Although the motion loss may appear weird at first, fusion frequently produces favorable outcomes [57].

4.5 Complementary Treatment and Supplements

Complementary therapies can help ease some of the symptoms of arthritis, such as pain and stiffness, as well as some of the adverse effects of medicine. Relaxation practices, for example, can improve overall safety. Some of the most well-known treatments:

1. Acupuncture involves the insertion of thin needles into specific points on the body, which is said to help restore the natural balance of health by correcting imbalances in energy flow. There is evidence that it can help with osteoarthritis symptoms. NICE does not currently recommend this treatment for osteoarthritis.
2. The Alexander Technique entails becoming more conscious of your posture and moving more efficiently. It has been proven to be very efficient for back pain but is less marked for osteoarthritis.
3. Aromatherapy uses vegetable oils to support health and well-being. The oil can be vaporized, inhaled, exploited in showers and burners, or used as portion of a scented healing back massage. Aromatherapy Is Effective for Osteoarthritis Symptoms, according to Research No, yet some people enjoy the following advantages, such as relaxation support.
4. Although there is limited evidence that it is beneficial in alleviating osteoarthritis symptoms, a good massage can be relaxing and rejuvenating.
5. Osteopathy and chiropractic involve manipulating the body's alignment manually and applying pressure to soft tissues. The objective is to correct structural and mechanical irregularities, improve mobility, reduce pain, and facilitate the body's natural healing process. Chiropractice may provide relief in spine or extremity OA associated pain as reported in aretrospective study conducted to understand the impact of chiropractic management in patients with OA and spine pain. There is no specific scientific evidence that osteopathy is effective in the treatment of osteoarthritis [63].

Use of supplements: Arthritic patients frequently experiment with a range of supplements, including herbal medicines, vitamins, minerals, and supplements. There is minimal evidence that they improve arthritis or its negative effects in many patients. Before taking any supplements: 1. Research the supplements you intend to use; not all of them are suitable for everyone. 2. Consult your doctor or pharmacist to ensure if it is safe to combine with prescription or over-the-counter treatments. After taking medication, keep an impact diary to see if the supplement (s) are having an effect [58].

Glucosamine: Glucosamine is a substance that is present in the body, mainly in tissues like cartilage, tendons, and ligaments. It can also be obtained from the shells of crustaceans such as shrimp, crab, and lobster. Some studies have suggested that taking dietary supplements of glucosamine, particularly in the knee, may be useful in treating osteoarthritis. There seems to be proof that there is no such thing as instant pain relief. It will take several months to visualize if it works. If it doesn't work after 2 months, it possibly won't work [59, 60].

Chondroitin: Chondroitin is normally present in our body and is said to help make ligaments more versatile. Animal studies indicate that it may help slow cartilage disintegration. To a certain extent. Expect no progress for at least 2 months. Assuming the ligaments are badly damaged, chondroitin cannot be used [61].

Fish oils: Fish oil and fish liver oil are generally regarded good for the joints. There isn't sufficient information to say if it's effective. Fish liver supplements are often high in vitamin A, so it's important not to overeat. Fish oil supplements tend to be lower in vitamin A, so it's safer if you really desire to take benefit of the high fish oil content [62].

5 Herbal Medicines in OA

Herbal medicine refers to the purpose of different sections of medicinal plants. Herbology has a long practice of use outside of conventional medicine. It is the collection of information, skills, and practices that are used to preserve health as well as to prevent, diagnose, improve, or treat health. Many physical and mental diseases. The earliest written validation of the help of medicinal plants to formulate medicines was observed on his 5000-year-old Sumerian clay tablets at Nagpur. It includes 12 recipes and references over 250 plant ingredients, including alkaloids like poppy, henbane, and mandrake. The sacred Vedic publications of India pertain to healing with the help of abundant plants in the country. Pen TSao, a Chinese treatise on the utilization of roots and plants, was authored in 2500 BC by Emperor Shen Nong. Author of 365 remedies (dried bits of medicinal herbs). Many of them are still in existence today [64, 65].

The risks connected with herbal medications are introduced onto the market without a mandated safety or toxicological evaluation of their efficacy. Many of these nations also lack efficient procedures to control natural medicine manufacturing and quality laws [65]. Many countries face problems with regulatory status, safety and efficacy evaluation, quality control, safety monitoring, and insufficient or erroneous information about traditional supplementary items [66].

The difficulties in assessing safety and efficiency stem from the fact that the requirements, inquiry procedures, standards, and methodologies necessary to evaluate the safety and efficacy of natural medicines are more involved than those required for traditional medications and pharmaceuticals [67, 68]. The point is, no one can deny that it's a lot more perplexing. Routine medical care. A single home-grown pharmaceutical or medicinal plant may have hundreds of natural elements, and natural therapeutic items combined may include many more. This is essentially unimaginable when evaluating individual dynamic components in this way, especially if the natural product is a mix of at least two spices [69].

5.1 Rose Hip

Rose hip oil is extracted from dried *Rosa canina (R. canina*) fruits acquired from Hyben Vital in Langeland, Denmark. The fruit of the Rosaceae (rosebush) rose family *Rose hip* ranges in hue from red to orange. This species is indigenous to Europe and is widely dispersed there [70]. In fact, it is the most abundant rose species in Central Europe. Furthermore, the dog rose is endemic to portions of North Africa and Central Asia. European invaders transported *R. canina* to the Americas, South Australia, New Zealand, and southern Africa hundreds of years ago, where it escaped cultivation, naturalized, and now thrives in the wild [71].

R. canina is a big shrub or small tree with an arched trunk that grows to a height of 2.74 meters. The five-petaled blossoms, which range in color from white to pink and bloom alone or in tiny clusters in June and July, bloom alone or in tiny clusters. In September and October, the blooms are followed by persistent brilliant red berries, which are often referred to as fake berries (hips). The true fruit is a tiny hairy mass containing seeds in the rump. Dog roses are propagated through spreading, sucking, layering, and sowing, which is most commonly done by loin-eating birds. *R. canina* is tough to control due to its reproductive habits and massive size. Some countries have put in place control measures to prevent their spread and categorize them as invasive species [72].

Rose hip has long been utilized for its astringent flavor. It was claimed to relieve diarrhea, dysentery, thirst, coughing, and "blood vomiting." Nicholas Culpeper, an English herbalist, botanist, physician, and astrologer from the seventeenth century, observed that ripe hips were rendered temperate (usually a mixture made with sugar or honey), which was described as "gently binding the belly and diverting from humor and fluid flow." He also said that the dry, powdery loins dissolve stones, make urinating easier, and alleviate colic.

Rose hips are utilized in various formulations to treat a wide range of ailments such as colds, diabetes, diarrhea, edema, fever, gastritis, gout, stiffness, sciatica, renal and lower urinary tract diseases. They are also used as a diuretic and laxative, and for blood cleansing purposes. Additionally, they are used to enhance the flavor of several food items including jams, jellies, teas, soups, infusions, syrups, beverages, pies, bread, and wine, owing to their vitamin C content [73, 74].

In the northern region of Portugal, people consume the fruit in its raw form, and extracts or brandy are made by steeping it for its diuretic, anti-diarrheal, anti-rheumatic, anti-inflammatory, respiratory, decongestant, energizing, and tonic properties, as well as for treating skin infections. The young shoots and fruit are eaten uncooked, and the fruit is utilized to make spirits and cakes. Similarly, it is also produced in rural Cantabria, which is located in northern Spain [75, 76].

Although the FDA has not officially recognized *R. canina* as generally recognized as safe (GRAS) for use in food, extracts and oils obtained from other species of *Rose hips* such as *R. alba*, *R. centifolia*, *R. damascena*, *R. gallica*, and their variants have been approved for use in cosmetics, foods, and medicines. However, the USDA considers *Rose hips* from *R. canina* or *R. rugosa* as a food [77, 78]. The use of *Rose hip* or *Rose hip* extract is allowed as an ingredient in dietary supplements, provided that the manufacturer complies with current Good Manufacturing Practices (cGMPs) and notifies the FDA within 30 days of marketing if they make a structure-function claim. In the FDA's cGMPs for regulating dietary supplements, the term "*rosehips*" is mentioned multiple times in the preamble [79, 80]. The FDA provides detailed specifications and labeling requirements for different types of dietary supplements that contain rosehips, such as "*rosehips* dietary supplement" and "vitamin C from *rosehips* dietary supplement." [81].

5.2 Phytochemistry of *R. canina*

With the aid of tandem mass spectrometry, gas chromatography, high-performance liquid chromatography, thin-layer chromatography, diode array detection, and thin-layer chromatography, a new study was started to discover the chemicals found in *R. canina* fruits. These studies allowed for the differentiation of various fruit combinations from *R. canina* [82]. Future investigation should focus on finding additional substances that might be responsible for some of the plant's bioactive qualities that have been found in recent medical studies. Quantitative component studies, which are also lacking, might point to the creation of legal *R. canina* breeding and post-harvest control methods as well as support for therapeutic agents [83].

Triterpene

The terpene family is one of the most diverse and variable groups of natural phytochemicals. Over 4000 different complex molecules, many of which are typically outside the realm of chemical synthesis, are among them. Simple triterpenes can operate as signaling molecules, whereas complex glycosylated triterpenes or saponins provide pest and microbe protection. It can be put to a lot of different uses. Triterpenes, which are precursors to sterols, are made by both plants and animals. Sterols are crucial membrane structural underpinnings and, as steroid hormones, they also contribute to cell signaling. Triterpenes, however, are not thought to be essential for healthy development and growth. Among the components of rosehip, both simple and conjugated triterpenes are highly regarded [84].

Flavonoids

Phytochemicals called flavonoids are part of the phenylpropanoid family of compounds. Two aromatic rings are connected by three carbon bridges to form the fundamental backbone of a flavonoid. This skeletal structure is produced by two different biosynthetic pathways. One aromatic ring and a three-carbon extension are obtained via the malonic acid pathway via phenylalanine, and the other is obtained through the condensation of three acetic acid-derived units. The most prevalent substituents for flavonoids, which typically exist as glycosides, are sugars. However, flavonoids can have a variety of substituents [85].

Anthocyanins, flavones, flavanols, isoflavones, flavanols, and flavanones are the first six subclasses of flavonoids. The anthocyanins, which are beta-glycosides with a sugar in the third position, are the largest group of colored flavonoids. Anthocyanins work as attractants, enticing animals (pollinators) to flowers and fruits through visual cues. Another essential attribute of flavonoids is their capacity to protect cells from ultraviolet B (UV-B) exposure. While permitting visible wavelengths to pass through, they gather in the epidermal layers of the skin and capture harmful UV-B radiation [86, 87]. Compared to anthocyanins and carotenoids, flavones and flavanols trap light at fewer frequencies. Flavones and flavanols cannot be seen by the human eye because of this. Because they are linked to the UV patterns of flowers known as "Nectar Guides," they can appear to insects that perceive UV tones in a range of light. It has been demonstrated that isoflavones have a variety of biological functions, such as antibacterial and insecticidal qualities [88].

The in vitro findings from flavonoid bioactivity screens were supported by in vivo research on the resistance of plasma and lipoproteins to ex vivo oxidation after ingestion of flavonoid-rich meals. A lower incidence of infectious diseases, cancer, inflammation, heart disease, ischemic stroke, atherosclerosis, and other chronic diseases, is linked to consuming foods high in flavonoids, particularly fruits and vegetables. Quercetin, one of the few flavonoids, has shown fascinating bioactive properties in both in vitro and some in vivo investigations [89, 90]. Rutin and its glycosides (rutin and quercitrin, for example) have shown anti-inflammatory activity in gastrointestinal inflammation models, perhaps through downregulation of nuclear factor kappa-beta signaling. Quercetin may also influence eicosanoid biosynthesis, protect low-density lipoproteins (LDL) from oxidation, reduce clotting, and relax smooth muscle in the heart. Interestingly, the flavonoid tiliroside (kaempferol 3-O-d-(6-p-coumaryl)-glycopyranoside) discovered in *R. canina* dramatically reduced the oxidation of human LDL in vitro. It has been shown in humans to have anti-obesity properties as well as antioxidant, cytotoxic, and anti-complementary properties [91, 92].

Carotenoids

Tetraterpenoids called carotenoids absorb light with wavelengths of 400–500 nm. Carotenoids, which give fruits and flowers their colors, are therefore found in plants as red, orange, and yellow pigments. Prevents photochemical processes from occurring, particularly oxidation (radical scavenger) [93, 94]. Animals must obtain their carotenoids from their diet because they are unable to synthesize them. A 40-carbon structure with an isoprene base unit makes up the majority of carotenoids. There are typically two subgroups of carotenoids. (1) Oxygen-containing xanthophylls (lutein, zeaxanthin, cryptoxanthin, etc.); and (2) non-hydroxylated hydrocarbons (i.e., −carotene, −carotene, and lycopene). The structure of a carotenoid (the number of conjugated double bonds and the presence or absence of oxygen) has a direct impact on the compound's color [95, 96].

Dietary carotenoids have been linked to the prevention of angina pectoris, apoptosis induction, and mammary cell proliferation. It has also been proposed that carotenoids may aid in human prostate cancer prevention [97, 98]. The positive effects of carotenoids that have been discovered may be the result of this discovery, either because carotenoids are better suited to serve as indicators of high consumption of fruits and vegetables or because the effects of epidemiological studies have been attributed to substances unrelated to carotenoids [99, 100]. However, some carotenoids have reportedly been found to have intriguing physiological properties. According to human research, lutein and zeaxanthin, which are found in high concentrations in the macula of the human retina, may protect the outer segment of the macula and the retinal photoreceptors from oxidative stress are seen [101].

Diets high in lutein and zeaxanthin are associated with a lower prevalence of nuclear cataracts in older women and a lower risk of age-related macular degeneration. Additionally, it has been suggested that lycopene, when given in the form of tomato paste or extract, can treat non-eosinophilic airway inflammation and prostate cancer. Because it is a result of administering a combination of compounds, it is problematic [102, 103].

Vitamins

Vitamins are organic chemicals that are produced by plants and some lower animals. Vitamins play a variety of activities in the body, including coenzyme activity, precursor activity, antioxidant activity, calcium and phosphorus intake regulation, and coagulation regulation (blood coagulation). Numerous illnesses and diseases in humans are caused by vitamin deficiencies [104].

Vitamins that dissolve in water, like vitamin C and the B vitamins, cannot be stored by the body and must be consumed continuously through food. Water-soluble vitamins that aren't used are excreted. Recent studies have concentrated on the antioxidant activity of vitamins C and E [105].

Apart from scurvy prevention, which is attributed to vitamin C's role in collagen synthesis, vitamin C is involved in a number of significant enzymatic syntheses. It is crucial for the production of bile acids and the conversion of cholesterol to these acids. Vitamin E, which is assumed to work largely as an antioxidant, is thought to protect PUFAs of plasma membrane phospholipids and plasma lipoproteins. According to recent studies, vitamin E reduces protein kinase C activity, although the physiological significance of this impact is unknown [106].

Osteoblasts, which promote bone formation, and osteoclasts, which encourage the breakdown of mineralized tissue (breakdown of bone structure), control bone formation. Osteoclasts produce ROS (reactive oxygen species), and ROS encourage the breakdown of collagen chains, which is crucial for bone remodeling. Proteolytic enzymes like elastase and metalloproteinases can be activated by elevated oxidants, further harming the bone extracellular matrix. Antioxidant supplements may therefore aid in restoring bone mineral density (BMD) [107].

Ascorbic acid, a component of vitamin C, is crucial for procollagen and stable collagen secretion, both of which are necessary for the development of connective and bone tissue. *Rose hips* beneficial effects as an osteoporosis treatment are further supported by their high polyphenol content. Oxidative stress-related bone loss is known to be lessened by it. Strong evidence supports the idea that combining the seeds and skins of the *R. canina* subspecies helps people feel less pain and function better every day. It is evident that both the peel and the seed are required because a study on pure peel powder found no impact on patients' reported pain and discomfort [85, 108].

The beneficial effects of *R. canina* have not yet been fully explained in terms of their biochemical underpinnings, though. According to this perspective, the only molecule, a galactolipid by the name of GOPO that has anti-inflammatory properties, appears to be significant. Collagen plays a significant role in the healing process and the high natural vitamin C content in *R. canina* is readily absorbed. Linoleic acid which contributes to the COX-1 and COX-2 inhibitory effects found in rose hips may also offer an explanation in addition to triterpene acids [109, 110].

At the molecular level, OA involves an inflammatory process that produces excessive levels of RONS (reactive oxygen and nitrogen species). RONS generated by chondrocytes and associated with OA include superoxide, hydrogen peroxide, nitric oxide, and peroxynitrite [111]. Despite the fact that RONS is required as a second messenger in the control of normal physiological processes and as a destructive agent in the immune system's defense against pathogens, aberrant chondrocyte metabolism reduces its physiological buffering capacity [112]. An overabundance of anything causes oxidative stress. Proteins, lipids, nucleic acids, and extracellular matrix constituents can all be damaged by RONS overproduction. Induced cell damage and RONS signaling both amplify the inflammatory response at the same time. These comprise transcription factors, matrix-degrading enzymes (such as metalloproteinases MMP-3 andMMP-13), inflammatory cytokines (interleukins IL-1 and IL-6), and this process is closely linked to permanent cell cycle exit and chondrocyte senescence (also known as the "senescence-associated secretory phenotype") [113, 114].

TNF-α, IL-1, and IL-6 are pro-lipolytic inflammatory cytokines produced by adipocytes. Moreover, it prevents the synthesis of lipids. Lipids function as a negative feedback mechanism by suppressing the synthesis of type II collagen and proteoglycan in addition to promoting the production of prostaglandins, matrix metalloproteinases (MMPs), and other cytokines. In this method, pro-inflammatory cytokines cause bone resorption and cartilage matrix disintegration [115, 116].

5.3 Clinical Trial Study on Rose Hip Extract

This study aims to evaluate Reflex Plus's impact on people with osteoarthritis (OA). The study will last 12 or 24 weeks, not including the roughly 1-week screening period. Reflex Plus, a health supplement made of collagen hydrolysate and rosehip extract, is the test product under investigation. The supplement is believed to assist in the development of cartilage, which is essential for proper joint function and reducing arthritic pain. It is also helpful in managing joint discomfort and safeguarding cartilage. The primary aim of the study is to assess the difference in knee pain between the start and end of the trial, as determined by the WOMAC osteoarthritis index sum score, when comparing the supplement and placebo.

Study Phase: Phase 4

Condition: Osteoarthritis

Intervention: The dietary supplement contains 5 g of Reflex Plus Collagen Hydrolysate and 0.55 g of Rose hip Aqueous Extract. The placebo includes Fructose, Orange Flavor, and Sucralose.

Study: During the study duration, the Active Comparator Reflex Plus should be taken once a day before breakfast, using sachets.

Interventions: During the course of the study, the Reflex Plus placebo comparator dietary supplements placebo sachets should be consumed once daily before breakfast. Dietary Supplement is Placebo.

Status: Completed.

Rose hip extract contains galactolipids.-1,2-di-O-[(9Z,12Z,15Z)-octadeca-9,12,15trienoyl]-3-O-b-D-galactopyranosylglycerol, betulinic acid, oleanolic acid, ursolic acid, vitamin C, vitamin E, beta-carotene, lycopene and linoleic acid are all found in this supplement. Also contains monogalactosyldiglyceride and digalactosyldiglyceride. These active components control the inflammatory response and stop cartilage from being destroyed. Additionally, *Rose hip* extract has been shown to lower levels of the acute phase protein CRP and serum creatinine while also inhibiting peripheral blood polymorphonuclear leukocytes (PMN). Additionally, it was noted that *Rose hip* use lessens pain, stiffness, and disease severity while COX inhibits −2 and contributes anti-inflammatory properties. Rose hip powder was proven to be an effective dietary supplement for her OA knee patient. However, more research is needed to determine the therapeutic relevance of the reported good experimental outcomes.

6 Conclusion

OA is a frequent condition among the elderly. The first line of management consists of lifestyle changes and physical therapy, which is followed by analgesics and NSAIDs. However, these medications only treat symptoms and have no impact on how the disease develops naturally. Nutraceuticals refer to dietary supplements that are believed to modify the inflammatory process and, as a result, impact the natural progression of osteoarthritis. Collagen peptides are similarly effective in treating OA, although there are various formulations available on the market, each with its unique pharmacological effects. As a result, standardizing collagen peptide formulation is required before utilizing it to treat OA. Supplements containing collagen hydrolysate (CH) and glucosamine sulfate (GS) have been shown to be safe, however reports on their effects have been inconsistent. Despite lacking sufficient research, the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis has recommended the use of nutraceuticals as a first-line treatment option for managing OA. Rose hip powder is considered a valuable nutraceutical in the treatment of OA patients due to its anti-inflammatory, chondroprotective, and immune-modulatory properties. However, more extensive research is necessary to establish its efficacy in the future.

R. canina, also known as rosehip, is a remarkable and gorgeous medicinal plant. It is a very potent source of antioxidants and anti-inflammatory compounds and can grow in very rocky soils. Additionally, it contains a lot of vitamins, particularly vitamin C. *Rose hips* are very effective at treating osteoarthritis in humans and some animal models, according to a number of clinical studies. It is crucial to note that a dose response, one of the pillars of the evaluation of prescription drugs, has been confirmed for *Rose hip* subspecies. There is proof that *Rose hip* treatment may be beneficial for conditions like rheumatoid arthritis, cardiovascular disease, and skin conditions like wrinkles. However, the amount of active ingredients in *Rose hips* varies. Different types of rose seeds exist. To identify the species that offer the greatest potential, a careful comparative analysis is all that is necessary. It is interesting to note that the *R. canina* variant of osteoarthritis was able to reduce the use of emergency medications by up to 50%, particularly when discussing anti-inflammatory diets and anti-inflammatory plants. As a result, you can alter your diet and possibly reduce the cost of your prescription drugs.

Contents

Abstract

Complementing herbs with anti-hypertensive drugs is a standard health treatment for those with uncontrolled high blood pressure. This review compares the effects of completing different types of herbs with anti-hypertensive drugs on the physiological and biochemical outcomes such as blood pressure, body mass index

(BMI), waist-hip circumference, glucose levels, hemoglobin level, and lipid profiles. Ambulatory blood pressure measurements (ABPMs) help detect blood pressure variations and serve as a cardiovascular risk marker for hypertension patients. In the clinical practice guidelines, ABPMs are included in diagnosing and managing isolated office hypertension among pregnant women with masked or labile hypertension, as the figure denotes blood pressure readings over 24 h. Point-of-care (PoC) testing devices provide rapid results and information at the location and time of care, the measuring procedure of which can even be done at home. This practice eliminates negative biases, and PoC equipment is capable of chalking up measurements as accurate as those of laboratory-based biochemical analyzers. PoC reduces cost, waiting time, and the necessity for multiple visits improves quality of life (QoL) and increases accessibility of people living in remote areas to medical testing. However, taking ABPMs in actual clinical settings and PoC technology are grossly underutilized in the Asian regions. Hence, this chapter will review evidence of complementing herbal medicine with anti-hypertension therapies and the physiological and biochemical outcomes using ABPMs and PoC devices.

T&CM	traditional and complementary medicine
TC	total cholesterol
TCM	traditional Chinese medicine
TG	triglycerides

1 Introduction

Hypertension is a known global health issue that affects people regardless of age, race, and socio-economic background; it is a leading cause of premature death. Hypertension is defined as persistent elevations of systolic blood pressure (SBP) of

140 mm/Hg or greater and diastolic blood pressure (DBP) of 90 mm/Hg or more significant, taken at least twice on two separate occasions [1]. The prevalence of hypertension varies worldwide but is more common in low- and middle-income countries, and ironically, the number of affected people being undertreated is proportionally higher [2]. In Malaysia, the number of people diagnosed with hypertension from 2015 to 2021 increased by 14.1% among individuals above the age of 30 years [3].

The anti-hypertensive medication is often the first-line treatment; however, many people complement medication with herbal medicine to treat hypertension. Herbal medicine could be raw plants that are dried, minimally processed, mildly boiled, infused or herbal materials, herbal preparations, and finished herbal products that contain active ingredients, parts of plants, or other plant materials, or combinations [4, 5]. However, the safety and efficacy of concurrently taking herbal medicine and anti-hypertensive drugs have yet to be validated; the same goes for the potential risks and benefits. A study conducted by Asgary et al. [6] reported that anti-hypertensive drugs prescribed with *Vaccinium myrtillus* efficiently controlled hypertension. Besides blood pressure, beneficial evidence was also observed on parameters like BMI, glucose, and lipid when herbs such as *Vaccinium arctostaphylos* (Whortleberries) were complemented with anti-hypertensive drugs in treating blood pressure [7].

Subsequently, previous studies have also reported adverse effects associated with complementing herbal medicine and anti-hypertensive drugs. For instance, when *Nigella sativa* was taken with ACE inhibitors and diuretics in a study carried out in Indonesia, side effects such as dyspepsia, nausea, and constipation were observed among the participants [8]. Moreover, musculoskeletal pain, fatigue, breathlessness, itching, and even epigastric discomfort were exhibited among the patients who concomitantly consumed amlodipine with *Phyllanthus emblica* extracts [9]. Therefore, monitoring the physiological and biochemistry outcomes of using herbal medicine concurrently with any anti-hypertensive drug is imperative.

Globally, point-of-care (PoC) devices are increasingly popular monitoring instruments for measuring physiological and biochemistry outcomes near patients' bedside. PoC devices are handy in several settings, including remote areas. PoC-measured values obtained immediately within 5 min were comparable to those obtained in laboratories [10]. One of the prime PoC devices that measures physiological outcomes is the ambulatory blood pressure monitor (ABPM), a non-invasive tool that monitors repeated and continuous blood pressure over 24 h. This is useful as blood pressure varies throughout the day, and a single measurement may not be accurate enough to diagnose a person with hypertension [11]. Previous studies have reported that ABPM is the gold standard as it provides consistency and is an excellent diagnostic tool for hypertension [12].

Moreover, portable PoC devices can measure biochemistry parameters of lipid profiles such as cholesterol, triglycerides, glucose, and hemoglobin levels. PoC devices can provide producible physiological and biochemistry outcomes at a reduced cost, provide timely information regarding patients' health status, and reduce the necessity for multiple visits [12]. A home blood glucose monitoring device is essential for diabetes patients to monitor their glucose levels. In accordance, the ABPM and other PoC devices are extremely useful to patients taking herbal medicine anti-hypertensive drugs concurrently; they can make better decisions by observing the changes in blood pressure as well as the biochemistry level after ingesting both in different scenarios at a time, or at an additional time, in the short term or the long term, respectively. In addition, the monitoring devices must be user-friendly and suitable for individuals of all age groups suffering from chronic ailments.

A limitation was reported after using an ABPM in a study: less tolerability as patients may face difficulties self-fixing the machine. However, the ABPM blood pressure measurements have many advantages as they can be saved, downloaded, or printed and shown to medical personnel at clinical visits [13]. Moreover, a study conducted in Korea also elucidated similar beneficial outcomes of a PoC device known as the GCare lipid analyzer, which can measure lipid and glucose levels in a single machine. Other limitations of PoC devices reported are unreliable, unusable, and biased measurements compared to laboratory analyzers. Nevertheless, the PoC-produced measurements using capillary blood were in the acceptable range [14].

There are divergent outcomes of using PoC devices to gauge the concurrent effects of taking herbal medicine and conventional anti-hypertensive drugs. Thus, a thorough investigation among patients with hypertension is warranted. This chapter reviews the physiological and biochemistry outcomes of concurrently taking herbal medicine and anti-hypertension drugs among hypertensive adults.

2 Epidemiology of Herbal Medicine Use with Anti-hypertensive Drugs

Globally, the concurrent use of herbal and anti-hypertensive drugs to treat hypertension is a prevalent trend. In a study carried out among the South African communities, 21% of the study population was reported to have used traditional herbal medicine with anti-hypertensive drugs to treat their hypertension [15]. On the other hand, Jordan said an astounding 51.4% of the population uses local herbal medicine with anti-hypertensive medications, a trend similar to those in other countries like China and Iraq [16]. This could be attributed to the affordability and availability of these various local medicinal herbs and the strong beliefs of the communities in these countries to consume herbs as an effective means of curbing hypertension [16].

In Tanzania, 22.1% of the study population on anti-hypertensive drugs to manage hypertension used herbal medicine such as garlic, ginger, beetroots, papaya, moringa seeds, and Chinese medicine [17]. In a study carried out by Joachimdass [18] in a sub-urban setting of Malaysia, 30.6% of the study population was found to complement their medical treatment with self-prepared herbs such as *Centella Asiatica*, *Momordica charantia*, *Carica papaya*, *Cucumis sativus*, and *Parkia speciosa* with the highest usage. The previous study reported these factors were associated with complementing herbal medicine with conventional anti-hypertensive drugs: being females, having higher education levels, having high socio-economic backgrounds, and dealing with multiple co-morbidities [19].

Even though increasingly hypertensive patients are taking herbal medicine and conventional anti-hypertensive drugs concurrently, the physiological and biochemistry outcomes vary from patient to patient. In a previous study conducted in Tehran, Iran, a local herb, *V. arctostaphylos* berry, was complemented at different doses among subjects who were on prescribed anti-hypertensive drugs, the combinations of which were reported to control both systolic and diastolic readings [20]. The phytochemical compounds contained in the herbal plant, such as chlorogenic acid, anthocyanin, and others, produce no side effects in the study subjects [4, 7]. Similar findings were also observed in another study in Egypt; ginger slices were taken by the study population on ACE inhibitors [21]. However, in a previous study conducted among hypertension patients who used ginger powder alone did complain of gastrointestinal discomfort and diarrhea [22].

3 Evidence-Based Herbal Medicine Use in the Treatment of Hypertension

Even though many pharmaceutical drugs are readily available to treat hypertension, some people may prefer herbal medicine as an alternative and complementary therapy. Below are some evidence-based herbal medicines studied for their potential benefits and effectiveness in combating hypertension.

The first example is garlic (*Allium sativum)*, a renowned herb used since ancient times for its blood-pressure-lowering effects. In a clinical trial in Australia, the participants consumed two garlic capsules rich in a biochemical constituent named allicin over a 12-week intervention period [23]. The results showed that 11.8 mm/Hg significantly reduced the study participants' mean systolic blood pressure; specific blood lipid parameters like LDL and total cholesterol also registered improvements.

Besides, *hibiscus sabdariffa* is another herb that potently affects blood pressure readings. Based on a study published by Mckay and colleagues [24], it was discovered that drinking hibiscus tea for 6 weeks lowered systolic and diastolic readings by an average of 7.2 mm/Hg and 3.1 mm/Hg, respectively. In addition, the supplementation of hibiscus also brings about hypocholesterolemic effects because of its antioxidant properties, regardless of the age and gender of the consumers.

Furthermore, *Olea europaea* L. (olive leaf) extracts also exhibit blood-pressure-lowering effects in a clinical trial. It was reported that positive outcomes could be seen in blood pressure and lipid profiles due to the active phytochemistry constituent, namely, oleuropein, found in the olive leaf extracts. This is because oleuropein, a polyphenolic compound, inhibits angiotensin-converting enzyme (ACE) through its hypotensive actions [25]. *Momordica charantia* L. (bitter gourd) is commonly used to prevent hypertension. A meta-analysis study reported no significant difference after consumption of bitter gourd; however, reductions in systolic and diastolic measurements were observed among younger adults when used on a short-term basis [26].

Hypertensive adults should always be cautious when consuming herbal medicine and be more transparent about their usage to healthcare providers, as there could be some adverse effects, which may lead to poor hypertension management.

4 Evidence on Herbal Medicine Interaction with Anti-hypertensive Drugs

Nowadays, herbal medicine as an alternative or complementary therapy is rising. However, this herbal complementation to medical treatment may lead to potential interactions between the two, producing adverse effects on the body. Moreover, the effectiveness of conventional medication could also be impacted negatively because of the herbs' complementation. Hence, the following information sheds light on the interactions between herbal remedies and anti-hypertensive drugs.

On the other hand, Hawthorn is an excellent example of an herbal remedy that may improve blood pressure readings. On the other hand, there have been reports of explicit interactions between hawthorn and two classes of conventional first-line drugs that are typically used to treat high blood pressure. The drugs include beta-blockers, for instance, atenolol and propranolol, as well as calcium channel blockers like amlodipine. Both drugs work by dilating the blood vessels; concurrent intake of hawthorn may notably lead to a spike in the effectiveness of the drugs, which in turn causes repercussions like excessive lowering of blood pressure [27].

Panax ginseng (ginseng), which possesses ginsenoside-Rg3, is a steroidal saponin compound that provides anti-hypertensive effects. These outcomes are likely mediated by myogenic response inhibitions on blood vessels [28]. Nevertheless, interactions between ginseng and anti-hypertensive medications such as calcium channel blockers (amlodipine) have been noticed. A study by Jeon et al. [29] elucidated that this interaction may lead to elevated blood pressure readings and dire consequences as the drug's potency may be diminished. Similar outcomes of high blood pressure readings due to decreased effectiveness of drugs were also discovered when *Hypericum perforatum* (St. John's wort) interacted with calcium channel blockers, digoxin, and warfarin [27].

Furthermore, *Glycyrrhiza glabra* (liquorice root) is commonly used in beverages and as a herbal antidote. Research done by Deutch et al. [30] sheds light on the interfering effects of liquorice with hypertensive medication, such as ACE inhibitors. The active phytochemistry constituent, namely, glycyrrhizin, which is found in liquorice, causes interactions with anti-hypertensive drugs that are metabolized by Cytochrome P450 3A4 (CYP3A4), an enzyme found in the liver and intestine, which increases blood pressure. Conversely, *Salvia miltiorrhiza* (Danshen) can interact with diuretics and lead to uncontrolled hypotension outcomes [27].

Table 1 contains the types of herbs and drugs that lead to improvements when used concomitantly, as well as the phytochemical constituents and mechanism of action that lead to specific outcomes.

Table 1 Examples of herbal medicine with anti-hypertensive properties used in clinical studies

Author, year	Number of subjects	Type of herbs	Results and implications	Country
[20]	100	400 mg *V. arctostaphylos* berry leaf extract capsule	• The *V. arctostaphylos* berry leaf extract capsule significantly reduced systolic and diastolic blood pressure due to the presence of gallic acid, chlorogenic acid, and anthocyanin • Another study further justified that the anti-hypertensive effect of this leaf extract was indeed due to the presence of anthocyanin, chlorogenic acid, and quercetin • These constituents mediated actions such as endothelial nitric oxide synthase activation, ACE inhibition, as well as calcium antagonistic action [7]	Tehran, Iran
[21]	40	Ginger slices	• Blood pressure readings were controlled and found to be less than 120/80 mm/Hg over 1 month when ginger slices were complemented Improvements were attributed to the phytochemical constituents found in ginger such as gingerols when taken concurrently with conventional medicine When 1.2 g of powdered ginger was used instead of slices, reductions in blood pressure were still observed although not significantly. Overall, ginger is still deemed to possess hypotensive effects as it can inhibit ACE and work as an antagonist [22]	Menoufia University Hospital, Egypt

5 Evidence on the Integration of Herbal Medicine into the Conventional Medical Practices

Some types of complementary and herbal medicine practices directly integrated into the conventional medical methods in Malaysia, Shanghai, and Beijing are traditional Chinese medicine, acupuncture, and traditional massages. Herbal medicine practices are integrated with the mainstream of conventional medicine for various ailments, namely, chronic pain, post-stroke and cancer treatments, hypertension, and even for postpartum mothers who are in recovery. In Malaysia, 15 hospitals have started integrating traditional and complementary medicine (T&CM) into modern healthcare systems, including Malay, Chinese, and Indian traditional treatment practices, homeopathy, chiropractic, osteopathy, and Islamic medicine [31]. The T&CM system integration is similar to the application in Shanghai and Beijing, respectively; to receive herbal medicine, the patients must first seek help from Western medicine practitioners and obtain a referral letter with indications of their health problems.

In Malaysia, with a referral letter from a general practitioner, the patients can be treated by doctors who have majored in traditional and complementary medicine and assisted by trained nurses [31]. However, in Shanghai and Beijing, certified Traditional Chinese clinicians will treat patients with a referral [32]. It was reported that one-third of the patients who visited Yuetan Chinese Community Health Service (Yuetan CHS) in Beijing were referred to traditional Chinese medicine practitioners (TCM), as the conventional treatments were unsuccessful. Table 2 contains information on the types of T&CM provided and the specific types of diseases treated in these hospitals [31–34].

Integrating T&CM into modern medical systems is still an area of ongoing research, particularly in treating hypertension and other diseases at hospitals. Limited concrete evidence is available on the types of herbs that can be complemented with drugs and their potency in treating various disorders. Thus, it is of utmost importance to continually and extensively evaluate the efficacy of integrating herbal medicine into conventional medicine practices; it would be helpful for the relevant authorities to develop comprehensive regulatory frameworks for the usage and practice. Moreover, more quality research should be done to overcome the methodological limitations of integration in hospitals; adequate training and education should be provided to medical personnel on safely implementing the integration [35].

6 Anthropometry Measurements

Anthropometry is the quantitative measurement of the physical body using non-invasive tools such as height-measuring devices and weighing scales. The measures comprise height, weight, body mass index (BMI), head, waist, and hip circumferences, skin fold thickness, and waist/hip ratios, all of which can be utilized to assess the risk of cardiovascular diseases such as hypertension [36]. The measurements of waist/hip and the resultant ratios determine body fat distribution, which is correlated

Table 2 Examples of conventional medical practices with the integration of herbal treatments worldwide

Location	T&CM provided	Ailments treated	References
Cheras Rehabilitation Hospital, Kuala Lumpur, Malaysia	Basti therapy, Shirodhara, traditional massage and acupuncture	Chronic pain and post-stroke	[31]
National Cancer Institute, Putrajaya, Malaysia	Herbal therapy for cancer patients and acupuncture	Chronic pain, post-stroke, chemotherapy-induced side effects	[33]
Sungai Buloh Hospital, Selangor	Traditional Indian medicine (varmam therapy)	Pain management in knee osteoarthritis, shoulder, cervical and lumbar	[31]
Shanghai Yueyang Integrated TCM and Western Medicine Hospital	Traditional Chinese and Western medicine, massage disciplines such as tuina and acupuncture as well as dermatology	Spine, stroke, heart rehabilitation, and several disorders	[34]
Yuetan Chinese Community Health Service (CHS), Beijing	Acupuncture and herbal remedies for (Management of common and chronic diseases and physical rehabilitation)	Knee and back pain, headaches, menopausal symptoms, infertility, hypertension, gastrointestinal disorders, urinary problems, and emotional/mental problems	[32]

with hypertension and insulin resistance. In contrast, changes in fat mass contribute to raised blood pressure readings [37]. Therefore, anthropometry measurements taken at health facilities will facilitate identifying patients at risk for hypertension.

6.1 Body Mass Index (BMI)

Higher BMI levels are often associated with co-morbidities such as hypertension, diabetes, and elevated cholesterol readings. The following are some of the studies that examined the BMI outcomes of hypertensive individuals who consumed herbal products and conventional medicine at the same time.

A randomized controlled trial investigated the effects of *Cynara scolymus* (Artichoke) combined with the anti-hypertensive drug captopril on hypertensive patients' blood pressure and BMI readings. After an eight-week intervention period, the patients with co-morbidities such as obesity and diabetes were observed to show improvements in blood pressure and BMI levels [38]. Artichoke is rich in inulin and oligofructose phytochemistry bioactive compounds, which help maintain a balance in gut microbiota. This decreases the amount of inflammation in the body and promotes the modulation of hormones in the gastrointestinal tract, leading to BMI improvements [39].

Another study reported that green tea contains catechin polyphenols, which increase the hormone leptin, which maintains average body weight in the long term [40]. However, the reported results are inconsistent; it is uncertain whether the consumption of green tea improves weight loss and BMI levels. A study by Bogdanski and colleagues [41] reported no significant changes in the BMI of obese hypertensive participants when they complemented green tea extracts with anti-hypertensive drugs for 3 months. Hence, green tea consumption improves weight loss, inflammatory markers, and glucose homeostasis, but its effects on BMI require more research, mainly when used with anti-hypertensive drugs [40].

6.2 Fat Mass

The correlation between body composition and hypertension risk is inconsistent in the previous studies. Ye et al. [42] revealed a positive association between excess fat mass and elevated blood pressure among adults. Direct fat mass measurements require sophisticated equipment, such as machines with dual-energy X-ray imaging technologies and densitometry. Fat mass measurements are indirectly taken using the skinfold method and a bioimpedance machine [43]. The American Council on Exercise (ACE) has developed a guideline for men and women; men with fat mass percentages of above 25% and women above 32% are classified as obese. The following paragraphs explain the outcome of fat mass measurements for concomitant herbal medicine usage with anti-hypertensive drugs among hypertensive adults.

In a study by Boix-Castej'on et al. [44], hypotensive effects and the outcomes of fat mass percentage were observed for consuming two capsules of herbal medicine containing *Lippia citriodora* and *Hibiscus sabdariffa* extract, the participants of which were adults with stage-1 hypertension and were obese. Significant reductions were noted in fat mass percentage and systolic blood pressure readings. Moreover, the improvements in weight loss and BMI were also attributed to the participant's compliance with a regimen of proper exercise and diet. The combination of polyphenolic compounds such as verbascoside and hibiscetin from *Lippia citriodora* and *Hibiscus sabdariffa* was another probable reason for the reduction in fat mass percentage.

Another study reported effects on fat mass percentage among hypertensive adults who consumed flaxseed. The flaxseed, which contains lignans of secoisolariciresinol diglucoside, reportedly can lessen hypertension and diabetes; it can control obesity and bring about weight reductions due to the anti-inflammatory properties and presence of antioxidants [45]. The study participants with hypertension consumed the flaxseed for over 12 weeks, showing a significant reduction in BMI levels and overall fat mass percentage. A plausible reason could be the high amounts of soluble and insoluble fibers in the flaxseed, which help lose weight. Moreover, lifestyle factors such as regular exercise and a healthy diet contribute to the improvements [46]. However, more research is needed to properly implement self-management of body fat mass using herbal medicine and prescribed drugs.

6.3 Waist/Hip Circumferences

The waist/hip circumference (w/h) ratio is high among people with raised blood pressure and abdominal obesity [47]. However, there are plausible studies on the w/h ratio outcomes of hypertensive adults, particularly those who consume herbal medicine and anti-hypertensive drugs concurrently. The following studies detail the evidence obtained on the w/h ratios:

In a study by Dicks et al. [48], adults with hypertension and type 2 diabetes consumed flavanol-rich cocoa powder with multiple anti-hypertensive drugs for 12 weeks; the results showed a significant reduction of w/h ratios. The consumption of cocoa powder and anti-hypertensive drugs concomitantly reduced endothelin-1 system activation and inhibition of the ACE enzyme [49].

Reportedly, hypertensive adults who consumed herbal supplements containing hibiscus, olive leaf, and green tea with conventional medication experienced reductions in the w/h ratio and BMI levels, in addition to improvements in blood pressure readings [50]. Similarly, in another study, saffron consumed concurrently with anti-hypertensive drugs was reported to improve the w/h ratio and other anthropometry parameters due to the presence of carotenoids [51]. Carotenoids are a known antioxidant compound that prevents the damaging effects of singlet oxygen on human lymphocytes, reducing the risk of hypertension and obesity [52].

All in all, extensive research is still needed to investigate the outcomes of concurrent consumption of herbs and anti-hypertensive drugs in depth. Nevertheless, based on past studies of adults with co-morbidities such as hypertension or obesity, concomitant usage of herbal remedies and medicines seems to yield positive changes in w/h ratios.

7 Blood Pressure

Blood pressure is the pressure exerted on the walls of the arteries due to the force of the blood pushing against the walls when the heart pumps blood to all parts of the human body. It is measured in millimeters of mercury (mm/Hg) by an office blood pressure machine or ambulatory blood pressure monitor (ABPM); it is written using two figures determining a person's blood pressure levels. Systolic blood pressure is the first value measuring the pressure in the arteries when the heart beats. Subsequently, the second figure denotes the diastolic blood pressure. It is indicative of the pressure when the heart rests between beats. An ideal blood pressure reading would be 120/80 mm/Hg; when an individual has readings above 140/90 mm/Hg, that person would be classified as suffering from hypertension. It is vital to realize that the tasks may vary throughout the day depending on a person's schedule, stress levels, and several other factors that may affect the quality of life and the likelihood of being predisposed to other co-morbidities. Thus, monitoring blood pressure readings is essential and should be undertaken regularly at a health facility or at home [1].

7.1 Ambulatory Blood Pressure Monitor (ABPM)

Blood pressure measurements via an ambulatory blood pressure monitor have elucidated the effectiveness of detecting blood pressure variations and the prevalence of cardiovascular risk markers in hypertensive patients. The device can be used as a treatment guide for detecting treated but uncontrolled hypertension, as it can measure the blood pressure readings throughout 24 h. On the other hand, in the clinical practice guidelines, ABPM is included to diagnose and manage isolated office hypertension among pregnant women, masked and labile hypertension [11]. ABPM is the gold standard as it provides consistency; it is a better predictor for hypertension as repeated measurements can be done, leading to more excellent reproducibility of average blood pressure taken with increased precision [12].

In a clinical trial in Poland, the hypertensive patients consumed standardized tomato extract with diuretics and acetylsalicylic acid concomitantly over a 4-week duration; the average blood pressure reading measured using ABPM was 127/78 mm/Hg. The readings were repeated every 15–30 min over 24 h. When combined with the drugs, the presence of lycopene from the extract brought about a synergistic hypotensive effect that significantly improved both systolic and diastolic blood pressure readings [53].

Similarly, another study in China reported that the average 24-h ABPM reading was 131/84 mm/Hg, and the measurements were repeated every 20–30 min at the baseline appointment and after 8 weeks. The Chinese herbal formula, Songling Xuemaikang capsule (SXC), was used with losartan, which improved overall blood pressure readings. The changes could be attributed to puerarin, the active ingredient of Pueraria lobate found in SXC, as it can upregulate mRNA expression of ACE-2 and reduce plasma angiotensin II levels [54].

7.2 Office Blood Pressure Monitor

Since the olden days, sphygmomanometers, or office blood pressure monitors (OBP), have been the fundamental tool for measuring blood pressure. The measurements obtained via the OBP make diagnosing and managing hypertension easier as patients could be referred for treatment to prevent raised blood pressure readings [55]. However, readings obtained using OBP machines may come with errors due to masked hypertension. Thus, to avoid such mistakes and increase the accuracy of tasks, the machine should be calibrated by comparing the readings with those obtained manually, and the measurements should be triplicated to acquire an average assignment [56].

Moreover, some other steps could be taken to prevent errors: ensure the patients are seated comfortably without talking and have rested for a few minutes before beginning with the measurements [56]. In a study carried out in Thailand among hypertensive adults who consumed an array of herbs with anti-hypertensive drugs, the average blood pressure reading was 147/81 mm/Hg as measured by an office blood pressure machine. Two readings were taken at 15 intervals and then averaged

[57]. Thus, compared to readings obtained via ABPM across varying studies, the OBP measurement seems to give elevated blood pressure outcomes.

Lai and colleagues [54] explain two significant reasons for the higher blood pressure readings obtained when measured using an office blood pressure machine, compared with those obtained using the ABPM in this study and other previous studies. The first reason could be attributed to the phenomenon known as white-coat hypertension. When an office blood pressure machine measures an individual's blood pressure, the person tends to be less relaxed due to the presence of the medical personnel or equipment. However, several steps have been taken to mitigate the situation. The following reason could be this: office blood pressure measurements are commonly accepted in the morning before the patients consume their prescribed medicine, and readings tend to be higher during the day. In contrast, ABPM readings are taken many times at regular intervals over 24 h, even while a person is asleep at night; besides, there are no external factors that may cause a spike in the readings.

8 Point-of-Care Technology Evaluation and Biochemical Outcomes

Point-of-care (PoC) devices and their utility for patients' self-management of chronic disease states have been well known since the onset of the COVID-19 pandemic. In clinical settings, PoC devices provide rapid laboratory diagnostic results; they are handy monitoring tools for managing patients and titrating medication doses [58]. Several situations have prompted the transition to using PoC devices: the convenience of self-monitoring at home, further improving disease management and healthcare cost-effectiveness.

Many devices are available for home use to manage chronic disorders such as diabetes mellitus, hypertension, congestive heart failure, and anticoagulation. Many of these devices have built-in software capabilities, enabling patients to share important health information with healthcare providers via a computer. Official visits to health facilities revealed long turnaround times for patients to receive results and attend follow-up consultations; in comparison, results are immediately generated using a PoC device, and appropriate actions can be taken as soon as possible. The frequency of HbA1c produced by the PoC device is higher than in laboratories. However, another study on PoC devices reported varied sensitivities for detecting covid-19 antiCOVID-19 lower for IgM, and higher for IgG compared with those of the gold standard, automated chemiluminescent immunoassay [59]. In another study, the newly developed SARS-CoV-2 PoC device was claimed to provide higher sensitivities of neutralizing antibody production. Even though the acquisition of immunoglobulin and neutralizing antibodies varies according to vaccine type, age, days after vaccination, pain degree after immunization, and immunization diseases, this PoC device can be used to give clinical recommendations; it is a decision tool to advise a person whether to receive additional therapy through the immediate rapid testing [58]. A multi-centered cross-sectional study conducted at nine hospitals in Guangzhou reported the risk of having dyslipidemia by examining blood lipids using a PoC device [60]. An analysis of the PoC survey was conducted remotely in Australia; the findings showed timely access to pathology results and subsequent follow-up of patients for treatment, which was practicable despite the long distances to the nearest laboratory [61].

Utilizing PoC devices could be a quick and helpful way to assess health outcomes when herbal medicine is used as a means of self-management, which can then evaluate the statement that "herbal medicines are all safe." It is feasible to introduce PoC devices in China; the widespread use might raise dyslipidemia awareness, improve treatment, and facilitate better control.

9 Blood Glucose Level

Patients with diabetes and hypertension may be high-risk candidates for heart and brain disorders. Blood glucose levels must be adequately controlled along with other cardiovascular risk factors.

9.1 Fasting Blood Glucose Level

For hypertensive patients with metabolic syndrome, consuming Yiqi Huaju Formula, a traditional Chinese herbal medicine mixture, in addition to standard care, significantly improved fasting blood glucose and other assessed parameters [62]. In a different trial, patients with metabolic syndrome who took Pycnogenol® maritime pine bark extract for 6 months had a reduction in fasting blood sugar levels, going from a baseline of 123 mm/Hg to 106.4 mm/Hg after 3 months and eventually to 105.3 mm/Hg at the end of the study [63].

A unique green aquatic plant called Wolffia globosa mankai is a dietary source of high-quality protein. In a randomized crossover study with participants who were abdominally obese, the intervention group was given a shake containing Wolffia globosa to replace dinner. In contrast, the control group was assigned a shake containing yogurt. The study participants showed lower fasting blood sugar levels the following morning (83.2 mg/dL to 86.6 mg/dL) [64].

In India, diabetes and hypertension are common. Fenugreek seeds are frequently taken to treat diabetes and hypertension. Patients with diabetes got 10 gm of fenugreek seeds in hot water daily in a randomized, controlled study, while the control group did not. The patients had type 2 diabetes mellitus, managed by diet, exercise, and insulin or oral hypoglycemic drugs. According to statistical analysis, the study group's fasting blood glucose levels significantly decreased in the fifth month, whereas the study group's HbA1C significantly reduced in the sixth month [65]. On the other hand, treatment with 162 mg/d of onion skin extract quercetin decreased ABP in hypertension patients [66]. Prehypertensive males who consume an olive leaf extract high in phenols do not significantly affect fasting blood glucose levels or other measures [67].

9.2 2-Hour Post-Prandial Blood Glucose Level

Clinical investigations have indicated various advantages of herbal medications in lowering blood glucose. A herbal product containing nettle leaf 20% (w/w), berry leaf 10% (w/w), onion and garlic 20% (w/w), fenugreek seed 20% (w/w), walnut leaf 20% (w/w), and cinnamon bark 10% (w/w) was fed to study participants who failed to control blood glucose with two oral medications and were unwilling to inject insulin for 12 weeks in a double-blind, controlled study by Parham et al. [68]. In tests conducted during fasting and two hours after eating, the glucose level was dramatically reduced after consuming the herbal medicine mixture. Additionally, glycated hemoglobin A1c (HbA1c) dropped from 0.33% to 0.20%. Finally, after using the herbal treatment, the degree of insulin resistance dramatically decreased from 1.9 to 1.4.

An oral glucose tolerance test has improved due to the effects of olive leaf extracts. According to a study, borderline diabetics' blood glucose levels dramatically lowered at 30 and 60 minutes when 1 g of olive leaf was supplied with 300 g of white rice. In both cases, it was believed that the polyphenols in olive leaf extracts inhibited the activity of intestinal and salivary amylases. However, it is also possible that the aglycones in olive leaf extracts compete with the glucose released from food in the gut for glucose receptors, reducing absorption. According to the study, the use of olive leaf extracts by prehypertensive men revealed no significant effects on fasting glucose, insulin, or other indices [69].

10 Lipid Profile

Total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), and low-density lipoprotein cholesterol (LDL-C) are lipid profile measures in the blood that are frequently evaluated. Increased TC, TG, LDL-C, and decreased HDL-C are signs of dyslipidemia. Dyslipidemia is a known modifiable risk factor for hypertension, ischemic heart disease, and stroke. Participants with dyslipidemia received treatment with the Unani polyherbal medicine Jawarish Falafili (JF) in a prospective randomized research. When JF was ingested, significant decreases in mean blood TC, TG, and LDL-C were seen at baseline compared to the control group who took atorvastatin for dyslipidemia. However, neither group's mean serum HDL-C levels significantly changed after treatment [65]. Compared to the control group in a different trial, consumption of olive leaf extract was also linked to physiologically significant decreases in TC, LDL-C, and TAG, with no change in the effect on HDL-C [70]. The TC and LDL-C reductions seen using olive leaf extracts and JF could be equivalent to decreased total CVD risk when considering earlier statin trials [69]. It is unknown what processes underlie the lipid-lowering effects of herbal therapy.

The consumption of phenolic components of herbal medicine, on the other hand, appears to reduce the activities of critical cholesterol-regulatory enzymes, 3-hydroxy-3-methylglutaryl-CoA (HMG-CoA) reductase (the main target of statins), and acetyl-CoA cholesterol acyltransferase (ACAT), leading to a reduction in cholesterol biosynthesis [71]. Contrarily, neither in the entire trial group nor in the subgroup of hypertension patients did quercetin supplementation for 6 weeks impact fasting serum concentrations of total cholesterol, LDL cholesterol, or HDL cholesterol. As opposed to this, Lee et al. [72] discovered that supplementing male smokers with quercetin (100 mg/d) for 10 weeks considerably decreased fasting serum concentrations of total cholesterol and LDL cholesterol and significantly elevated serum HDL-C. The length of quercetin administration, the study participants' baseline characteristics, and the dosage of quercetin taken internally may be to blame for these conflicting outcomes.

Traditional medicine uses *Phyllanthus emblica*, a plant high in antioxidants, tannins, and vitamin C, to cure various illnesses. Patients with essential hypertension were randomly assigned to receive a *Phyllanthus emblica* capsule (500 mg) or a placebo twice daily, in addition to their usual medications, over 12 weeks in a randomized controlled experiment. In the beginning, the treatment and placebo groups were comparable. Patients with essential hypertension have a satisfactory safety profile when taking *Phyllanthus emblica*. However, using *Phyllanthus emblica* failed to improve oxidant status, antioxidant capacity, or lipid profile, and it did not result in any further drops in systolic and diastolic blood pressure levels [9].

In Egypt, the management of hypertension has traditionally involved the use of *Hibiscus sabdariffa* and *Olea europaea*. When captopril 25 mg, *Hibiscus sabdariffa*, and *Olea europaea* were administered to Egyptian patients with grade 1 essential hypertension for 8 weeks, the subjects' mean triglyceride levels significantly decreased [73].

11 Hemoglobin Level

Some signs of rising hemoglobin (Hb) levels may cause a rise in systolic and diastolic blood pressure. A HemoCue Hb 201+ analyzer (HemoCue AB, Ngelholm, Sweden) routinely analyses Hb levels in finger stick capillary samples. In research by Atsma et al. [74], both male and female adults with hypertension showed a positive rise of Hb with both SBP and DBP. Several scientific explanations for the connection between Hb and blood pressure have been proposed. First, pulse wave velocity, a measure of arterial stiffness, is closely correlated with Hb, which raises SBP and DBP [75]. Furthermore, Hb may relax smooth muscle cells, change peripheral resistance, and thus modify blood pressure by scavenging nitric oxide (NO) generated in the endothelial cells that line blood arteries. Increased free Hb might bind to NO, which tightens the blood vessels and raises blood pressure [76]. Third, elevated Hb concentrations would result in elevated blood viscosity. Previous studies have shown that increasing hematocrit and hemoglobin levels cause blood to become more viscous, possibly damaging cardiovascular function by affecting blood pressure. Iron content in herbal medicine and its ability to treat anemia make it a popular drug. Hematopoiesis is significantly influenced by iron. However, since other elements such as alkaloids, flavonoids, saponins, tannins, calcium, zinc, and vitamins C and K contribute to the body's ability to absorb iron, the therapeutic potential of the herbs cannot be determined only based on their availability of iron. For instance, vitamin C helps the body absorb iron [77]. Some herbal medicines were beneficial for treating iron deficiency anemia, but studies that are more likely to be accurate have primarily focused on this influence on blood pressure control.

12 Conclusions

Blood pressure, blood glucose levels, blood lipids, and hemoglobin levels can all be affected, albeit to differing degrees, by the various herbal medicine protocols. Other confounding factors, most likely conventional medicines, smoking, exercise, co-morbidities, and food, have been the primary contributors to the changes in hypertension treatment. Certain targeted herbal medicine elements have the potential to complement hypertension treatment. However, it is essential to evaluate each patient's pharmacological therapy individually.

Abstract

Inflammation is the hallmark of several immune defence mechanisms against pathogenic as well as non-pathogenic challenges. However, uncontrolled inflammation can often lead to chronic pathological conditions such as diabetes, autoimmunity, cancer, and other cardiovascular diseases. Present anti-inflammatory drugs pose serious physiological threats in the long run, showing severe side effects and thus, there is a huge demand for alternative drugs. Several medicinal plants used by different ethnic, indigenous, and tribal communities across the world show anti-inflammatory and wound-healing capabilities. One such indigenous community of Sub-Himalayan Bengal of India is the Rajbanshi community, who have established their own folk medicine system. This chapter discusses in detail the traditional Rajbanshi healers, the medicinal plants they use, their preparation of the medicinal formulation, as well as route and dose of administration. Plants used to treat various inflammatory ailments such as allergy, common cold, diabetes, skin diseases, cut, burn, gastrointestinal problems, and wound healing properties are enlisted in this chapter. The study also evaluates seven of the plants surveyed for judging their capability to scavenge free radicals, inhibit delayed-type hypersensitivity, and stimulate antibody production in the murine model. This chapter provides an opportunity to unravel new anti-inflammatory drugs with the potential for immunotherapeutic applicability.

SRBC	Sheep Red Blood Cells
TBA	Thiobarbituric acid
TCA	Trichloroacetic acid

1 Introduction

Inflammation is a host immune response to protect the body against pathogenic and non-pathogenic infection and injury. As a general mechanism, inflammation gradually initiates the healing process to recover from the local tissue injury and restores the body's homeostasis. However, the case of chronic inflammation and severe hypersensitivity, where the healing process is not restored properly, can lead to chronic inflammatory conditions affecting several organs such as the heart, liver, lungs, kidney, pancreas, gastrointestinal tract, or even brain. These situations can lead to serious inflammatory-associated disorders such as diabetes, pancreatitis, atherosclerosis, Alzheimer's, rheumatoid arthritis, osteoarthritis, tuberculosis, asthma, pulmonary fibrosis, COVID-19, and cancer [7, 16–18, 20, 51, 52, 54]. Synthetic anti-inflammatory drugs are beneficial in treating inflammatory diseases but with prolonged use, they can cause severe life-threatening side effects. Non-steroidal anti-inflammatory drugs/ NSAIDs, such as aspirin, ibuprofen, fenoprofen, indomethacin, diclofenac, flurbiprofen, naproxen, piroxicam, tenoxicam, and oxaprozin which are commonly used, cause serious deleterious effects leading to cardiovascular risks, gastrointestinal and hepatotoxicity, hypertension, and even neurotoxic effects [3]. Thus, newer and alternative approaches, showing comparable effectivity with less or no deleterious side effects need to be taken into consideration. Medicinal plants contain many phytoconstituents which show comparable efficacy as synthetic drugs [57]. There are several traditional methods practised by indigenous communities to treat inflammatory illness using herbal formulations [19] that need to be explored for new and safer anti-inflammatory drugs.

Plants are one of the most important source of medicine in many parts of the world [13–15, 21–31, 35–37, 49, 50]. In spite of enormous progress in modern medicine and pharmaceutical research, the use of medicinal plants still remains an important part of daily life. With the arrival of modern chemistry in the mid-eighteenth century, the ability to isolate, and purify specific compounds and synthesize them in large quantities became the foundations of the current pharmaceutical industry. Natural plant extracts of therapeutic relevance are of paramount importance as reservoirs of structural and chemical diversity [1, 40] and are used commercially across the globe. India represents a country of diversified ethnic groups with rich knowledge of biological resources and traditional medicines. Here, Ayurveda still remains dominant, compared to modern medicine. The basis of the ancient wisdom of Ayurveda medicine was that a system as complicated as the human body could not easily be cured by single compounds, but rather to reset harmony of the spirit and body by the administration of combinations of medicines. Different indigenous communities in India treat their daily ailments based on the knowledge that they have been sharing among their community for generations [12, 33]. Rajbanshi community is one such indigenous group of people, who have been living for thousands of years in the Terai and Brahmaputra valleys of Eastern Himalaya, which is rich in biodiversity. Rajbanshis are traditionally agriculturists and at the same time being deeply rooted in mother nature they have acquired great knowledge of plants with medicinal values in due course of time [44]. Rajbanshi traditional healers, called Kabiraj, have vast knowledge regarding the use of plant species for the treatment of various ailments. The new millennium with its developed technology has provided many opportunities for validation of the uses of natural products. The present work would like to unravel the vast knowledge of the Rajbanshi people regarding their ancient traditional medicinal practices, mainly in curing inflammation and healing wounds. At the same time, we have also put efforts to validate the efficacy of some of these medicinal plants through laboratory experiments which could provide preliminary data to explore their potentiality in a larger perspective as anti-inflammatory agents. We believe this work will pave the path for further work in the field of immunotherapy against inflammatory diseases.

2 Overview of Herbal Medicine Practices in the West Bengal Area of India

West Bengal is a state of India, situated between 27°13′15″ to 21°25′24″N latitude and 85°48′20″E 89°53′04″E longitude and the total area that the state covers is 88,752 Km^2. The state has diversified landforms, with mountains, plateaus, hills, plains, and coastal regions. In the northern region, it has the Himalayas and in the south, it has the Bay of Bengal and the Sundarbans coastal area. Due to this varied geographical pattern, West Bengal is rich in biodiversity with respect to both its flora and fauna. There are several ethnic and tribal communities in West Bengal, in the southern region there are mainly the Santhals, Koras, Mundas, Mahali, Kora, Meches, Lodhas, Bhumijs, Oraon, Kherias, and in the northern districts there are mainly the Rajbanshis, Koches, Meches, Rabha, Lepcha, Gorkhas, and Adivasis [48]. All of these communities stay very close to nature, mostly nearby forests, and have enormous knowledge regarding the use of medicinal plants, which has been passed to them from one generation to another. Folk and ethnic medicine has become an integral part of their culture and tradition. Almost every house in the community has medicinal plants that are used as a regular source of remedy to deal with day-to-day health problems such as cuts, injuries, burns, fractures, fever, headache, diarrhoea, skin rash, allergy, etc. Usually, at first, they try to cure the health problem happening in the family with their own indigenous knowledge of household herbal remedies. And in case it is not being cured by them, they approach the traditional healers. The traditional healers are commonly known as Ojha, Kabiraj, and Mahan, on whom the local people depend for their treatment either due to their age-old faith or also often due to their financial constraints [2].

Every medicinal plant that is being used for treatment has been given a local name in the vernacular language by the community people. Among the varied parts of the plants being used, the aerial parts are mostly preferred in preparing the medicine [46]. A study by Sarkar and Mandal [47] mentioned that the Santal, Munda, Lodha, and Mahali tribes have their own traditional way to treat different ailments, where they use different plants such as *Shorea robusta, Andrographis paniculata, Adhatoda vasica, Caesalpinia pulcherrima, Calotropis gigantea, Butea monosperma, Cajanus cajan, Tagetes patula, Ocimum sanctum, Psidium guajava,* and *Moringa oleifera*. For curing diarrhoea, the Santal and Lodha tribe often use roots of *Shorea robusta*, leaves of *Psidium guajava,* and also bark and leaves of *Butea monosperma*. Leaves and roots of *Datura metel* and *Calotropis gigantea* are used by Santal, Munda, and Lodha community for treating dog bites. Various parts of *Cajanus cajan* is used by the Munda and Lodha community to treat Jaundice. The Santal and Lodha community use roots and leaves of *Andrographis paniculata* during snake bite. *Adhatoda vasica* is used for treating cough and cold, *Datura metel* for treating asthma by Santal, Lodha, and Munda communities. However, these tribes now believe that the practice of treating diseases with ethno-medicines is diminishing gradually due to the decline in the number of plant species in their localities and the adjoining areas. Another work was carried out by Paul [42] in the district of Purulia, which is located in the western part of West Bengal and is predominated by Toto and Birhor tribes. The study says that these tribes as well as local communities use several plants for treating fever, such as stems of *Tinospora cordifolia*, roots and leaves of *Calotropis gigantea*, roots of *Hemidesmus indicus* and *Thysanolaena agrostis* Nees, the entire plant of *Andrographis paniculata* wall, and the bark of *Randia dumetorum.* Leaves and roots of *Breynia retusa* Alston and leaves of *Ocimum canum* for treating pneumonia and cough, the entire plant of *Alangium salviifolium* for snake bite, bark and leaves of *Streblus asper* for bronchitis, and roots of *Clitoria ternatea* and *Mimosa pudica* are used for treating infertility. Indigenous people of this district also used leaves/bulbs of *Allium cepa* Linn, the entire plant of *Andrographis paniculata* wall, and the entire plant of *Polygonum plebeium* R.Br. for treating diarrhoea and dysentery.

Raj and co-workers [43] did an extensive study by interviewing indigenous people in the villages nearby Chilapatta Reserve Forest, which is situated in the sub-Himalayan region of West Bengal. The indigenous people of this area mostly suffer from stomach-related disorders such as gastroenteritis, dysentery, stomach pain, indigestion, stomach worm, diarrhoea, and ulcers, and thus, there are about 40 different plant species that are being used for stomach-related ailments. Next to that are the plant species that are used for healing different types of cuts and wounds such as *Justicia adhatoda* L., *Justicia gendarussa* Burm. f., *Alternanthera brasiliana* (L.) Kuntze, *Rauvolfia serpentina* (L.), *Thespesia populnea* (L.), *Asparagus racemosus* Willd., *Ageratina adenophora* (Spreng.), *Ageratum conyzoides* L., *Eupatorium odoratum* L., *Oroxylum indicum* (L.) Benth, *Bryophyllum pinnatum* Kurz., *Shorea robusta* Gaerth f., *Acacia catechu* (L. f.) Willd., *Cassia sophera* L, *Leucas aspera* (Willd.) Spreng, *Melastoma malabathricum* L, *Melia azedarach* L, *Moringa oleifera* L, *Datura metel* L, *Solanum nigrum* L, *Christella dentata*

(Forssk.), *Cissus repanda* Vahl, *Alpinia malaccensis* (Burm.f.) Roscoe, *Curcuma caesia* Roxb., and *Curcuma longa* L. For treating cough and cold they mainly used *Andrographis paniculata* (Burm.f.) Wall. *ex* Nees, *Justicia adhatoda*, *Centella asiatica* (L.) Urb, *Alstonia scholaris* (L.) R. Br., *Phoenix sylvestris* (L.) Roxb, *Terminalia bellirica* (Gaertn.) Roxb, *Elaeocarpus ganitrus* Roxb. ex G. Don, *Ricinus communis* L, *Ocimum sanctum* L, *Melia azedarach* L, Moringa oleifera L., *Myristica longifolia* Wall, *Syzygium cumini* (L.) Skeels, *Piper nigrum* L., and *Lantana camara* L. Another study by Dutta et al. showed that the tribal population of Cooch Behar used different herbal formulations mainly to treat abdominal disorders, jaundice, liver problems, and intestinal worms, and also to heal cuts and wounds [9].

This traditional knowledge has become the basis of primary healthcare being practised by different ethnic and indigenous communities of West Bengal. The use of traditional medicine is important for providing effective treatments that are prepared for the individual's needs. Additionally, Ayurveda, a traditional Indian system of medicine, has been shown to be effective in treating a variety of conditions, including diabetes, heart disease, and cancer. Furthermore, traditional medicine has been found to be an effective form of preventative care, in this region. Herbal formulations prepared by making powder or paste of different parts of plants are mainly used for curing diseases such as ulcers, diabetes, skin diseases, vomiting, diarrhoea, liver problems, fever, neurological disorder and gynaecological disorders.

3 Herbal Medicine Practices in West Bengal

3.1 Study Area and the Survey Work

The study area comprises north of West Bengal, India, located at 26°22′N latitude and 89°29′E longitude, covering the Cooch Behar district (Fig.1a). Local practitioners/traditional healers were interviewed through structured questionnaires. A total of 20 informants, where 13 of them were traditional healers or Kabiraj, were interviewed to obtain details about their methods of treatment. Written consent was taken from each interviewed person, who was willing to share their knowledge. The information was recorded on the basis of the names of the plants, their medicinal use, the formulation of the herbal preparation, and the methods of administration. Interviews and discussions were conducted in the local Rajbanshi language.

3.2 Leaf Extract Preparation

Most of the plant specimens were collected from the medicinal garden of traditional healers and some from nearby natural vegetation. The collected plant specimens were preserved with 2% mercuric chloride in ethanol and were deposited at the Department of Botany, University of North Bengal for identification. A unique accession number was assigned to each herbarium specimen by the Department of Botany. For extract preparation, leaves of the plants were collected, cleaned, shade

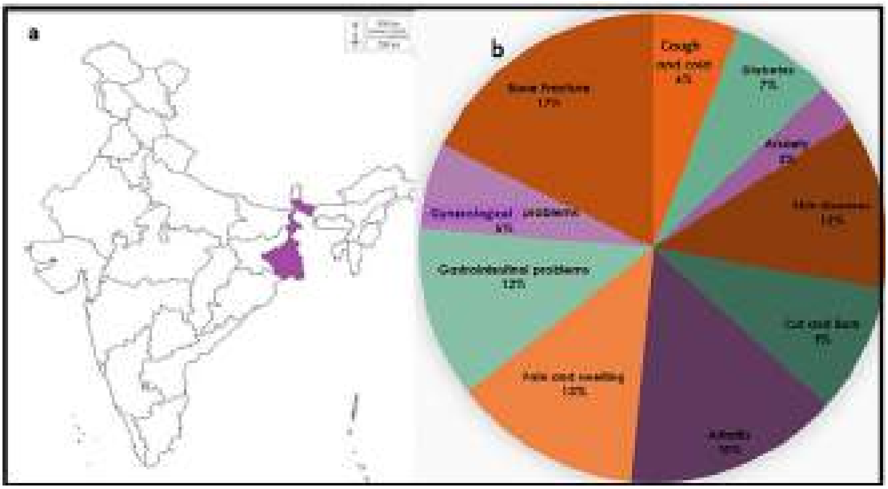

Fig. 1 (**a**) Location of West Bengal in the country map of India; (**b**) Different types of diseases cured by the Rajbanshi community with their indigenous herbal preparations

dried, and ground into powder form with a mechanical grinder. For each type of plant, 10 gm of ground leaves were then soaked in 100 ml of ethanol (80% v/v) in a 1:10 ratio and placed for 3 days in a magnetic stirrer. After 3 days, the extract was filtered first with Whatman paper (2) followed by a Millipore syringe filter (0.22 mm). The dry weight of the extracts was determined by evaporating to dryness through Rotary Vaccum (Buchi). Seven plants were chosen for further investigations, namely, *Ageratum conyzoides* (ACE), *Centella asiatica* (CAE), *Cajanus cajan* (CCE), *Mikania micrantha* (MME), *Coccinia grandis* (CGE), *Cleome spinosa* (CSE), and *Drymaria diandra* (DDE).

3.3 Free Radical Scavenging Assay

Inflammation leads to the generation of reactive oxygen species (ROS), which in due course of time causes oxidative stress and damage to the tissue. Natural compounds which are capable of quenching/scavenging ROS could be considered a potential anti-oxidant and anti-inflammatory agent. Thus, free radical scavenging assays were performed.

3.3.1 2,2-Diphenyl-1-picrylhydrazyl Radical Scavenging (DPPH) Assay

The protocol followed by Mahdi-Pour et al. [39] and Patel et al. [41] was considered for DPPH scavenging assay with some modifications. Different concentrations of 2 μl of extracts containing 0.0292 mg/ml, 0.0584 mg/ml, 0.0876 mg/ml were mixed with 800 μl of DPPH solution in methanol. The solution mixture was incubated for 30 min in the dark at room temperature. Gallic acid (GA) was used as a positive control. At 517 nm, the optical density (OD) was estimated through a spectrophotometer (HITACHI, U-2900). The free radical scavenging was calculated as a percentage of inhibition according to the following formula:

$$\text{Percentage of DPPH radical \% scavenging} = \{(A0 - A1)/A0\} \times 100$$

Where absorbance of the control reaction is denoted as A0 and A1 is of the extracts/ethanol.

3.3.2 Hydroxyl Radical Scavenging Assay Through Malondialdehyde (MDA) Generation

In vitro hydroxyl radical scavenging properties of different plant extracts were investigated using Fe^{2+}- ascorbate- EDTA (Ethylenediaminetetraacetic acid)- H_2O_2 system. The reaction mixture of 1 ml final volume contained L-ascorbic acid (1 Mm), 2-deoxy D-ribose (2.8 mM), ferric chloride (2 mM), hydrogen peroxide (H_2O_2) (1 mM), EDTA (1 mM) and phosphate buffer (4 mM) was incubated at 37 °C for 1 h with different concentration of leaf extract (0.146 mg/ml and 0.0584 mg/ml). TBA-TCA reagent containing 2.8% trichloroacetic acid and 1% aqueous thiobarbituric acid (TBA) was administered into the mixture. The reaction mixture was then boiled (15mins) for generating pink-coloured MDA-TBA chromogen. Once the reaction mixture had cooled the OD was estimated at 532 nm in UV- spectrophotometer (Make-Hitachi, U2900) [5, 45]. Mannitol (MA) a well-known anti-oxidant was used as a positive control to compare the level of efficacy of the plant extract. The efficacy of different plant extracts and ethanol as vehicle control was calculated assuming the level of MDA generation to be 100% in tubes deprived of extracts or ethanol and the inhibition percentage was calculated with the following formula:

$$\text{Percentage of inhibition} = \frac{\text{MDA generated in untreated tube} - \text{MDA generated in extract/ethanol treated tube}}{\text{MDA generated in untreated tube}} \times 100\%$$

3.4 Experiments on Animal Model

3.4.1 Animal Model

Swiss albino mice of 10–12 weeks (both male and female) were considered for in vivo experiments. Each experiment was repeated at least thrice taking 10 mice in each set. All experimental procedures were followed as guided by the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA), Govt. of India. The Institutional Animal Ethics Committee of Cooch Behar Panchanan Barma University approved the protocols (Ref. No. CBPBU/IAEC/ZOO/010/2018).

3.4.2 Delayed Type Hypersensitivity (DTH) Assay

Delayed-type hypersensitivity (DTH) reactions represent a clinically important class of immune responses that has wide-ranging significance for various health and disease conditions [39]. Several pathogens such as mycobacteria, different proteins, as well as haptens can induce DTH reaction [34, 55]. Thus, to judge the anti-inflammatory property of the plant extract, delayed-type hypersensitivity model induced by a strong hapten, 2,4 dinitrofluorobenzene (DNFB) was considered. Swiss albino mice were injected subcutaneously with DNFB made in acetone. For primary sensitization, 0.000001% DNFB was injected in the subcutaneous region of the right foot pad of the mouse. The reinjection was done after 8 days on the left foot pad with 0.0001% DNFB. Different leaf extracts prepared in ethanol were administrated (25 μl dose) intravenously 1 h before resensitization. For each experiment, an equivalent amount of ethanol (alcohol) was administered in a separate set of animals 1 h prior to resensitization [6]. The size of the inflammation of the foot pad (diameter) was measured through a slide calliper and has been indicated as the degree of inflammation.

3.4.3 Hemagglutination Assay (HA Titre)

To understand whether the plant extract can stimulate antibody production with its treatment, HA titre was performed, where the antigen (Ag) and antibody (Ab) reaction can be observed as a visible agglutination ring at the bottom of the titre plate. Sheep erythrocyte (SRBC) was used as an antigen for immunization. Different leaf extracts/ethanol (25 μl dose) were injected intravenously 1 day before immunization. 0.1 ml of the 25% of SRBC (Ag) was injected intravenously in the lateral tail vein of the mice for immunization. The mice were sacrificed on the seventh day of immunization and serum was collected and stored at −20 °C. On the day of the experiment, the serum was heat inactivated at 56 °C for 45 min in the water bath. The heat-inactivated serum (Ab) was sterilized by passing through Millipore filters (0.45 μm, Sartorius) before experimentation. The experiment was carried out in a 96 well micro-titre plate where the first well contained 1:10 dilution of the heat-inactivated serum and the second well onward two-fold serial dilution (1:20 to 1:20,480) was made with PBS. Then in each well, 0.1% of antigen (Ag) was added before the incubation for 4–6 h at 37 °C in a humidified atmosphere. The reciprocal value of serum dilution in the last well giving positive haemagglutination reaction was considered as agglutination titre value. There will be the least agglutination in one of the wells down the row, beyond which no agglutination is visible, is considered as the end point of agglutination [4, 53].

4 Study Outcome

4.1 Outcomes of the Survey

A total of 20 informers were interviewed during the survey work. In this study we found that most of the healers are aged over 50 years old. The common diseases that were treated with different medicinal plants were cough and cold, diabetes, anxiety, skin diseases, cut and burn, pain and swelling, bone fracture, gynaecological problems, as well as gastrointestinal problems (Fig. 1b).

During this review we have recorded 37 specimens of medicinal plants used by the traditional healers, which are *Mikania micrantha, Stephania japonica,* Ageratum conyzoides, *Cleome spinosa, Cajanus cajan, Sida acuta, Eclipta prostrata,* Centella asiatica, *Ludwigia perennis, Drymaria diandra, Peperomia pellucida, Coccinia grandis, Vitex negundo, Plumbago zeylanica, Terminalia arjuna, Andrographis paniculata, Leucas zeylanica, Cissus quadrangularis, Heliotropium indicum, Calotropis procera, Scoparia dulcis, Trapa bispinosa, Ocimum sanctum, Achyranthes aspera, Euphorbia hirta, Eucalyptus globulus, Ocimum gratissimum, Abroma augusta, Mirabilis jalapa, Trichosanthes dioica, Piper nigrum, Mangifera indica, Tinospora cordifolia, Momordica charantia, Moringa oleifera, Azadirachta indica, and Curcuma longa* (Fig. 2, Tables 1 and 2).

Fig. 2 Medicinal plant used by Rajbanshi community for treating inflammatory diseases and for wound repairing and healing: *1. Mikania micrantha* 2. *Stephania japonica 3.* Ageratum conyzoides *4. Table 1 Medicinal plant used by Rajbanshi community for treating various inflammatory diseases and for wound healing and repairing. The scientific name, common name, parts used, its preparation, and treatment are mentioned

Sl no.	Scientific name	Local name	Parts used	How it is being used	Ailments cured by Kabiraj
1	*Mikania micrantha*	Ashamlata	Leaves, stem	Boiled with water and decoction	Eczema, fungal infection, wound healing, stomach ache
2	*Stephania japonica*	Muchilata	Leaves, root	Mixed with other plants and boiled with water	Astringent, healing bone fracture, diarrhoea, fever, headache, urinary diseases
3	*Ageratum conyzoides*	Uchundi/ Bonpudina	Leaves, whole plant	Paste of the leaves mixed with other plants	Arthritis (joint inflammation), antifungal, bleeding control
4	*Cleome spinosa*	Hurhure	Leaves	Decoction	Bacterial infection, swelling, wound healing
5	*Cajanus cajan*	Arahar	Leaves, fruit	Leaf decoction	Jaundice; dysentery, wound healing
6	*Sida acuta*	Banmethi/ kureta	Leaves, whole plant	Decoction, juice of the leaves	Skin diseases, fever, common cold, wound healing
7	*Eclipta prostrata*	Keshraj/ kalakeshari	Whole plant	Paste with coconut oil	Promote hair growth, insomnia, dermatitis
8	*Centella asiatica*	Thankuni	Leaves	Two to three leaves were chewed daily during early morning, paste the leaves and apply 1–2 drops to the eye	Stomach problem, dysentery, conjunctivitis, wound healing
9	*Ludwigia perennis*	Bon lobongo	Leaves, roots	Boiled leaves or paste	Used to lower down fever and also for skin cut and wound healing
10	*Drymaria diandra*	Hargila	Whole plant	Plant juice	Laxative, inflammation
11	*Peperomia pellucida*	Luchipata	Whole plant	Plant juice/leaf paste	Stomach problem, cut and wounds

(continued)

Table 1 (continued)

Sl no.	Scientific name	Local name	Parts used	How it is being used	Ailments cured by Kabiraj
12	*Coccinia grandis*	Telakochu	Leaves and fruit	Fruit used as vegetable	Diabetes, osteoarthritis
13	*Vitex negundo*	Nishinda	Leaves	Mixed with different plants with mustard oil, honey, and water and directly applied to the affected area	Arthritis (joint inflammation)
14	*Plumbago zeylanica*	Agechita/ Chitrak	Leaves, roots	Powder of the leaves, paste of the leaves and roots	Piles, common cold cough, improve digestive system
15	*Terminalia arjuna*	Arjun	Bark	The bark of the tree was dried, ground, and then mixed with water/ milk	Heart-related problems, bone fracture
16	*Andrographis paniculata*	Kalmegh	Leaves	One or two washed leaves soaked in water overnight were chewed	Control diabetes, health tonic, treat intestinal worm
17	*Leucas zeylanica*	Dondokolosh	Whole plant	Used as a leafy vegetable (sauté with mustard oil), decoction	Fever, body dche, treat stomach parasite
18	*Cissus quadrangularis*	Harjora	Whole plant	Mixed with other plants with different solvents	Arthritis (joint inflammation), pain, healing of broken bone
19	*Heliotropium indicum*	Hatisur	Whole plant	Mixed with other plants with mustard oil and honey	Arthritis (joint inflammation), healing of broken bone
20	*Calotropis procera*	Akanda	Leaves	Mixed with other plants with mustard oil and honey, roasted leaves applied directly in inflamed area due to arthritis	Arthritis (joint inflammation), pain
21	*Scoparia dulcis*	Chinigur	Leaves	Juice of leaves with water taken orally	Diabetes, jaundice, skin diseases
22	*Trapa bispinosa*	Jolsingara/ paniphol	Fruit	Fresh fruits, or dry fruits made into powder	Helps to clean bowel system, treating ulcers

(continued)

Table 1 (continued)

Sl no.	Scientific name	Local name	Parts used	How it is being used	Ailments cured by Kabiraj
					and wound, flour of fruit is nutritious for health
23	*Ocimum sanctum*	Tulsi	Leaves	Juice of the leaves mixed with honey	Helps to treat cough, cold, and throat infection
24	*Achyranthes aspera*	Apang	Leaves/ roots	In the form of juice for oral consumption or for local application on skin	Consumption of juice helps to treat asthma, cough, pneumonia Local application of the juice helps to treat skin rash and itchiness Brushing tooth with the stem of helps to cure toothache
25	*Euphorbia hirta*	Dudhiya	Leaves	Juice made up of tender leaves	Used to cure respiratory diseases like asthma and bronchitis and irregular menstruation
26	*Eucalyptus globulus*	Eucalyptus	Leaves	Leaves were mixed with other plants to prepare paste	Used to treat arthritis; smoke from the burnt dried leaves helps to reduce cough
27	*Ocimum gratissimum*	Ramtulsi	Leaves	Leaves are crushed and mixed with honey	Helps to treat cough and cold
28	*Abroma augusta*	Ulotkombol	Root, bark, stem	Extracts from root, stem, and bark	Helps to cure gynaecological problems
29	*Mirabilis Jalapa*	Sandhyamalati	Leaves	Juice of the leaves	Leaf juice applied on the wound for healing

Almost all parts of medicinal plants were used for the preparation of medicinal formulations. However, leaves were used mostly compared to roots, stems, or flowers. Depending upon the disease two or more parts of the plants were used to prepare the formulation for the treatment. The mode of application of medicines was topical, orally, or by inhaling the smoke. Herbal preparations were often mixed with mustard oil, coconut oil, honey, or milk. It was observed that many of the traditional

Table 2 List of herbal formulation prepared by Rajbanshi Kabiraj for the treatment of different ailments

Sl. No.	Herbal Ingredients	Solvent	Procedure	Result
1	Leaves of *Trichosanthes dioica* *Curcuma longa* Roots of *Asparagus racemosus*	Water	Leaves were mixed with *Curcuma longa* and roots of *Asparagus racemosus*, crushed and mixed with water	The filtered portion is taken daily to cure allergic problems
3	Seeds of *Syzigium cumini* Internal white part of *Mangifera indica* seed	Honey	All of the ingredients were dried and ground in powder form. After that mixed with solvent for preparation of pills and sun dried.	This combination is very much effective for cough and cold and diabetes
4	*Andrographis paniculata* *Vitex negundo* G*lycyrrhiza glabra* *Azadirachta Indica*	Water	All the ingredients were sun dried, ground into powder form and prepared as pills	One pill every day in empty stomach will help to cure worms of abdomen and also important for healthy stomach
5	V*itex negundo* *Azadirachta indica* *Neolamarckia cadamba* *Datura metel* *Allium sativum* *Curcuma longa*	Mustard oil	All the ingredients were boiled in mustard oil until the oil becomes black	Its helps in pain of arthritis
6	*Vetiveria zizanioides* Rice (*Oryza sativa*)	Water	Roots of the grass were mixed with rice which was soaked overnight and made into paste. The paste was taken after meal	Helps to cure Haematuria and hematemesis
7	*Centella asiatica,* *Leucas zeylanica*	Water	All the ingredients were boiled with water and then dried as pills	Pills are taken after meals and its very much effective for jaundice, body ache, abdominal dysfunction
8	*Datura metel* *Calotropis procera.* *Curcuma longa*	Mustard oil	All the ingredients were made into paste and then mixed with mustard oil and boiled for 20–30 mins. The content was then filtered and the oil collected was used.	This oil is very helpful for reducing pain and inflammation caused by fracture of bone
9	*Withania somnifera*	Water, ghee	A thick paste of all the ingredients was prepared	Its helps in arthritis and also help in joining of

Table 2 (continued)

Sl. No.	Herbal Ingredients	Solvent	Procedure	Result
	Cissus quadrangularis *Leucas zeylanica* *Bambusa polymorpha* *Moringa oleifera* *Terminalia arjuna* *Tragia involucrata* *Piper nigrum* *Zingiber officinale* *Vitex negundo*	(clarified butter)	and applied on the area of fracture or on the area of dislocated bone	bone and also helps to reduce the pain of bone dislocation
10	Leaves of *Trichosanthes dioica* *Asparagus racemosus* *Phyllanthus emblica* *Terminalia chebula* *Curcuma longa* *Tinospora cordifolia*	Water	All the ingredients were ground and boiled with 250 ml of water for 30 min. The filtered water was taken every day on an empty stomach	Its helps to cure allergy

healers were interested in treating bone-related problems, like fractures of bone, dislocation of bones, and arthritis. For treating bone fracture they prepare a paste of fresh leaves of *Cissus quadrangularis, Vitex nigundo, Calotropis procera*, and *Heliotropicum indicum* mixed with different solvents and the paste is applied directly on the affected area. According to the local healers *Mikania micrantha, Eclipta prostrata*, and *Sida acuta* are the medicinal plants used for skin, hair-related problems, and also for the treatment of allergies. Application of paste of *Eclipta prostrata* also known as Kalakeshari/Keshraj in vernacular language, helps in the regrowth of hair, dermatitis, and curing insomnia if the leaf paste was mixed with coconut oil. For treating cough and cold, a decoction of fresh leaves of *Ocimum sanctum* (Holy basil or Tulsi) was used. *Ocimum gratissimum*, *Piper nigrum*, and *Leucas zeylanica* were also used to treat cough and cold. *Piper nigrum*, known as golmorich, and its fruits are traditionally used for flavouring food recipes. Ranjbanshi community used it for treating asthma, cough, headache, menstrual pain, gastric problems, and urinary problems too. The roots of *Vetiveria zizanioides* ground with scented-soaked rice and the paste was consumed to cure Haematuria

Fig. 3 Some herbal medicinal formulation in the form of syrup and pills prepared by Rajbanshi community

and Hematemesis. According to traditional medicinal practitioners *Heliotropicum indicum* was very useful in treating conjunctivitis. *Tinospora cordifolia* also known as Guloncho in vernacular language is a deciduous climbing shrub that is traditionally used to cure diabetes, reduce hypertension, and also enhance memory. The methods of application of herbal formulations are different depending on the ailment being treated and are mentioned in Tables 1 and 2. In Fig. 3, different types of medicines prepared by Kabiraj's has been shown. Seven different plants which were mainly used to treat inflammation and for healing wounds by the Rajbanshi community were chosen for comparative analysis of their anti-oxidant, anti-inflammatory, and immunostimulatory activities (Fig. 3). The dry weights of the ethanolic leaf extract and their accession number are represented in Fig. 4.

4.2 Antioxidant Property of the Different Plant Extracts

4.2.1 DPPH Scavenging

In the present investigation, three different doses (0.0292 mg/ml, 0.0584 mg/ml, and 0.876 mg/ml) of different ethanolic leaf extracts have been considered. The percentage of inhibition of DPPH generation by different extracts has been compared to the blank set, where the purple colour gradually decolorizes into pale yellow indicating DPPH scavenging. Out of seven plant extracts , DDE, CAE, CSE, and CGE showed a high percentage of inhibition in all three doses compared to other extracts. Starting from the lowest dose to the highest dose, CSE exhibited the maximum inhibition, comprising 48.80 $\pm$ 3.38 (0.0292 mg/ml), 63.82 $\pm$ 7.39 (0.0584 mg/ml), and

Fig. 4 The identification accession number and the dry weight of the ethanolic leaf extract of seven different plants used for assessing their anti-oxidant, anti-inflammatory, and immunostimulatory properties

72.26 ± 3.23 (0.876 mg/ml), whereas with DDE and CGE the percentage of inhibition ranged between 41% and 50% from lower to higher doses. The percentage of inhibition was low with the lower doses of CAE, around 34% to 36%, however, with the highest dose (0.876 mg/ml) it showed 51.38 ± 3.37% of DPPH inhibition (Fig. 5). The result of CSE at 0.876 mg/ml dose was comparable to Gallic acid, a well-known anti-oxidant which exhibited inhibition of DPPH between the range of 74% and 86% from lower to a higher dose.

4.2.2 Hydroxyl Radical Scavenging

Hydroxyl radical is one of the major reactive oxygen species, formed continuously during the process of reduction of oxygen to water in living organisms. This hydroxyl radical that is being generated can cause a breakdown of disulphide bonds in several proteins, especially fibrinogen, which can lead to abnormal protein configuration as observed during cancer, atherosclerosis, and in neurological disorders. Thus, the present study investigates the protective effect of plant extracts against damage due to hydroxyl radical generation. Two different concentrations of ethanolic leaf extract were considered in the present investigation, 0.0584 mg/ml and 0.146 mg/ml to investigate the scavenging of hydroxyl ion generation. The concentration of malonaldehyde (MDA) generated in the reaction mixture is indicative of the degree of hydroxyl radical generation. The inhibition of hydroxyl generation has been compared with the blank set (Fig. 5).

MDA generation was found significantly lower in almost all the extracts in both the concentrations (0.146 mg/ml and 0.0584 mg/ml) except CCE, where the inhibition of hydroxyl generation was not significant compared to the vehicle control (Fig. 6). The level of inhibition of hydroxyl generation was highly significant for

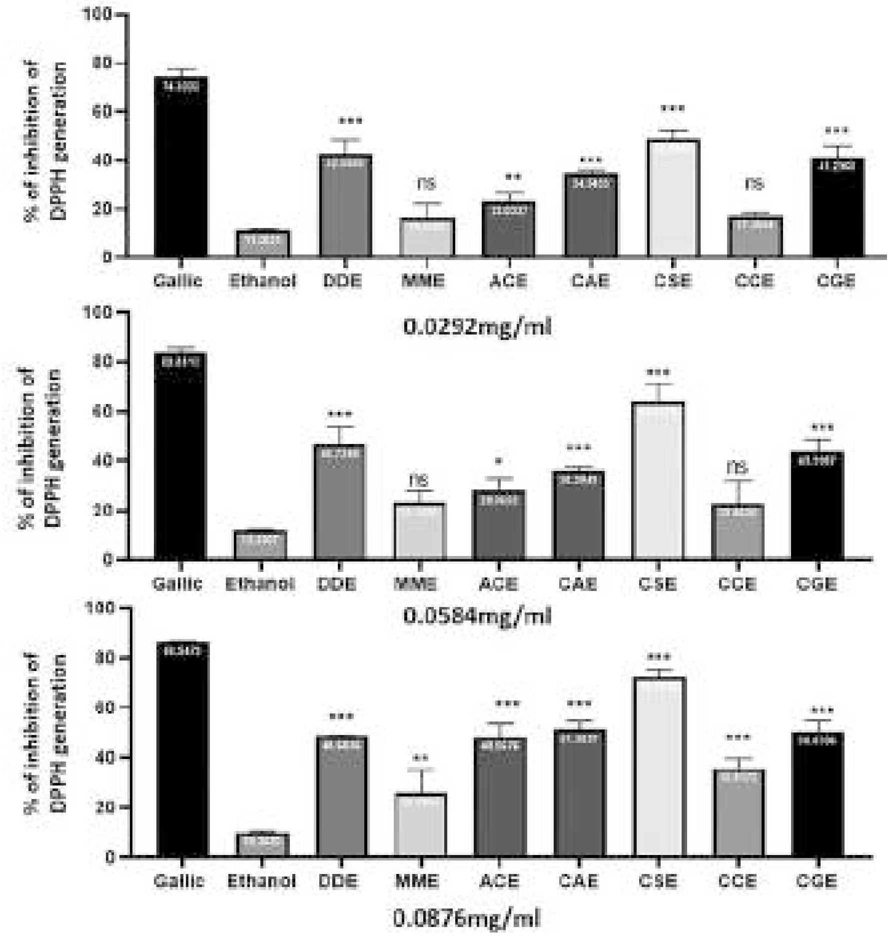

Fig. 5 Inhibition of DPPH generation by different plant extracts at 0.0.292 mg/ml, 0.0584 mg/ml, 0.0879 mg/ml. Gallic acid (Gallic) has been used as a positive control. Results were expressed as Mean ± SD ***$p < 0.001$, **$p < 0.01$, *$p < 0.05$, *ns* non significant. The significance of the antioxidant property has been estimated comparing the value of the vehicle control (ethanol)

CSE and ACE in both concentrations compared to others. However, CAE and DDE also exhibited high antioxidant properties compared to CCE and CGE. As observed in DPPH scavenging (Fig. 5), here also CSE could significantly inhibit MDA generation up to 52.84 ± 1.84% at 0.0584 mg/ml dose and 67.47 ± 3.94 at 0.146 mg/ml, dose indicating high potentiality in scavenging hydroxyl radical generation. ACE (58.21 ± 6.97%), CAE (57.55 ± 1.29%), CGE (55.44 ± 4.73%), and DDE (48.61 ± 7.24) at 0.146 mg/ml dose also showed better efficacy in inhibiting hydroxyl radical generation (Fig. 6). Mannitol (MA) has been used as a positive control to understand the potentiality of the antioxidant property of the extracts, where CSE showed to some extent similar effects with mannitol.

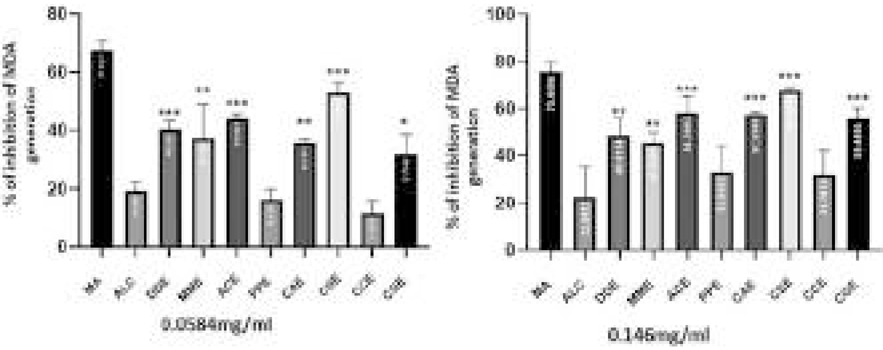

Fig. 6 Inhibition of hydr oxyl ion generation by different ethanolic leaf extracts at 0.0584 mg/ml and 0.146 mg/ml dose. Mannitol (MA) has been used as a positive control. Result expressed as Mean ± SD ***$p < 0.001$, **$p < 0.01$, *$p < 0.05$, non-significant has been denoted by ns. The significance of the antioxidant property has been estimated comparing the value of vehicle control (ethanol)

4.3 Anti-inflammatory Property of Different Plant Extracts

Delayed type hypersensitivity (DTH) is a vital defence against several pathogens such as *Mycobacterium tuberculosis, Mycobacterium leprae*, *Leishmania sp*, *Histoplasma*, *Coccidioides* fungi and is also involved in tissue rejection and cancer immunity [10, 32, 38, 55, 56]. Thus, to understand the potentiality of the different ethanolic leaf extracts for curing deleterious DTH response, DNFB, a strong hapten has been used to induce DTH reaction. In case of DTH reaction in the skin, there is an early infiltration of non-specific cells during primary sensitization with the antigen, which is followed by a specific response upon resensitization with the same antigen, which is mainly T cell-mediated response. This antigen-specific hypersensitive response leads to erythema (redness of skin) and oedema at the site of the antigenic challenge in the sensitized animal [4]. The hypersensitivity response is usually delayed, showing effects after 48–72 h of resensitization. In our animal model, the DTH response exhibited within 48 h and gradually got severe. Ethanolic leaf extracts were injected intravenously 1 h before resensitization. Among all the ethanolic leaf extracts, CSE showed the best result in alleviating the DTH inflammation faster. On the 12th day of resensitization with CSE treatment the paw size was 0.295 ± 0.023, which is almost the size of a 0 h normal paw (0.276 ± 0.014). The other extracts such as CAE (0.301 ± 0.005) and ACE (0.313 ± 0.012) also showed better inhibition compared to other extracts, however, the foot pad healing process was still in continuation (Fig. 7a). In the untreated and vehicle (ethanol) control groups, the foot pad muscles as well as paw digits were also lost in the course of inflammation. However, in the plant extract-treated groups, the foot pad loss gradually recovered and the inflammation also subsided much earlier than in the control groups. In the treatment groups, none of the mice exhibited digit loss (Fig. 7b). In the case of the control groups it took more than 3 weeks to subside

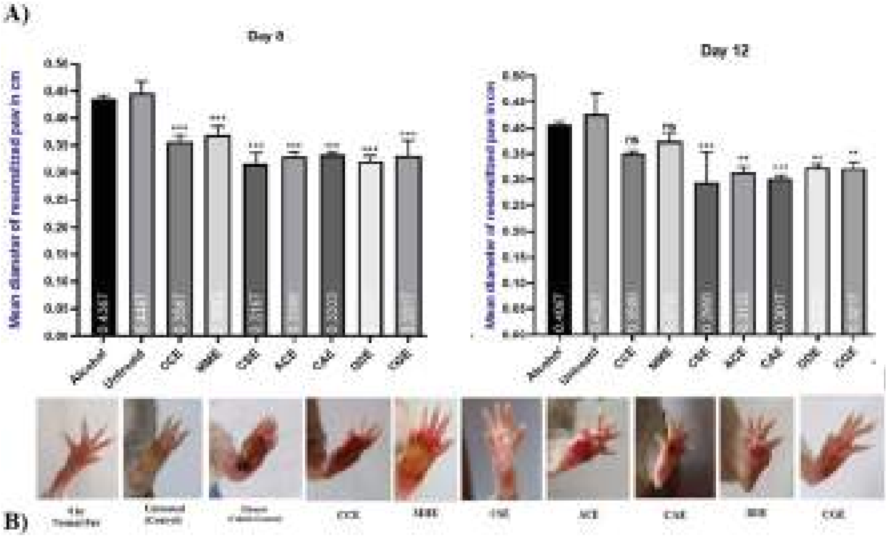

Fig. 7 (**a**) DTH (*delayed type of hypersensitivity*) reaction of resensitized paw in treated, untreated (control), and ethanol (vehicle control) at 8th and 12th days of DTH inflammation, represented by mean diameter in cm, considering the day of resensitization as day 0. Results are expressed as mean ± SD, ***$p < 0.001$, **$p < 0.01$ and *$p < 0.05$, non-significant value has been denoted by ns. (**b**) Photograph shown are of the resensitized paw on the 12th day. The far left photograph shows the normal paw (0 h, before the resensitization)

the DTH inflammation, although the vehicle control groups (ethanol) recovered a bit earlier than the untreated one. CSE-treated mice never exhibited digit loss and the inflamed foot pad eventually healed back to its normal size within 12 days of resensitization, suggesting its strong anti-inflammatory and wound-healing properties. The DTH paw treated with CAE and ACE extract resumed back to normal paw diameter in 13–14 days.

4.4 Immunostimulatory Property of the Different Plant Extracts

The antibody or humoral-mediated immune response during primary immunization was investigated through a haemagglutination titre (HA) assay, which measures the kinetics of primary immunity. The mode of plant extract treatment is similar to the DTH assay, where the mice were injected intravenously with different leaf extracts, 1 h before the immunization with sheep RBC (SRBC). It was interesting to observe that almost all the plant extracts were capable enough to boost antibody (Ab) production higher than the ethanol-treated and untreated mice, however, the level of stimulation varied (Fig. 8). In the serum collected from the primary immunized mice, the highest antibody (IgM) titre value was shown with CSE (*Cleome spinosa*) treatment which was 1:2560, followed by CCE (*Cajanus cajan*) 1:1280 and then MME (*Mikania micrantha*), ACE (*Ageratum conyzoides*), CAE (*Centella

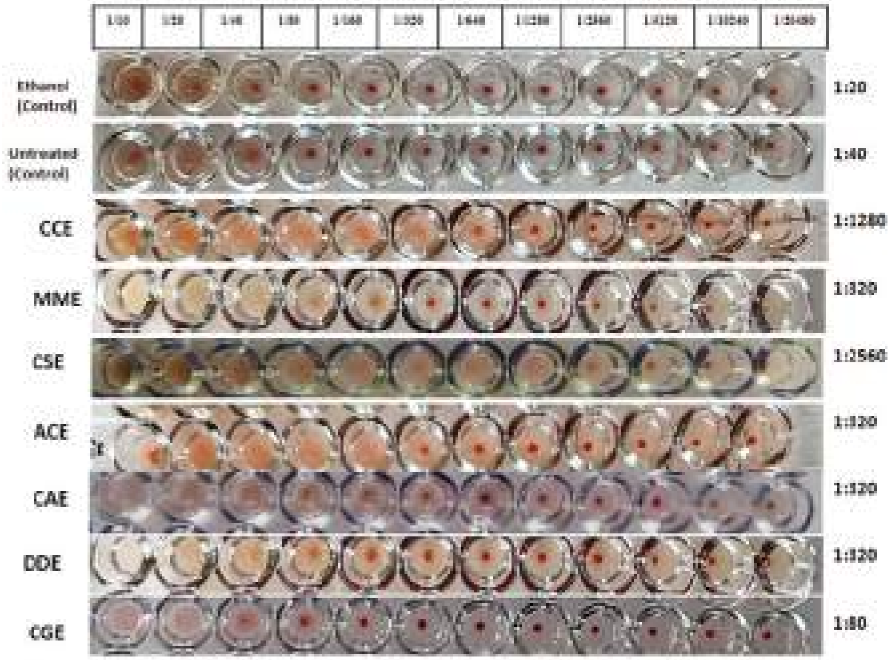

Fig. 8 Antibody response after the treatment of different plant extract. Hemagglutinin titre (HA) value shows the level of antibody production during primary immune response, mostly IgM (immunoglobulin M). The titre value mentioned on the extreme right indicates the last dilution of serum capable of agglutinating antigen

asiatica), DDE (*Drymaria diandra*) where all showed 1:320 titre value, and CGE (*Coccinia grandis*) showed the least with 1:80. Whereas, the Ab titre value was 1:20 with ethyl alcohol and 1:40 in the untreated group.

5 Discussion of Findings

Among the several ethnic communities in West Bengal, Rajbanshi community are the ancient tribe of Koch kingdom, belonging to the Indo-Mongoloid race. This chapter documents the ethnomedicinal knowledge shared by the Rajbanshi community of the Cooch Behar district of West Bengal, India. Cooch Behar is a historic location rich in culture and heritage, marked as a princely state since the sixteenth century, and is known to be the last ruling Hindu dynasty of Bengal before British rule. The Rajbanshi community inhabits mostly the northern part of West Bengal which comes under the sub-Himalayan region. The river system here plays an important role in its civilization by providing a source of water for irrigation and for drinking purposes. Torsa, Tista, Mahananda, Karatowa, and their tributaries are important rivers of this region. This Terai region of Bengal is covered with dense forest, inhabiting a huge number of exotic and wild species of flora and fauna. This area is often subjected to heavy rainfall and flash floods every year. These two important geographical features having rivers and forests makes them suitable for agricultural practices and at the same time makes them vulnerable to disease outbreak, due to drinking contaminated water during the rainy season and the dense forest that harbours parasitic diseases. The diseases that have always been prevailing in this region are dysentery, diarrhoea, cholera, malarial fever, smallpox, goitre, whooping cough, common cold, and skin diseases. In spite of the fact that the people were affected with serious diseases, the healthcare facility was never up to the mark. Due to a lack of proper healthcare facilities, the community had to be dependent on their indigenous traditional herbal medicine. In almost every household in this community, a herbal medicinal garden exists, this way they also contribute in conserving the species. Traditional medicine has been utilized by indigenous communities for centuries and the practice is still deeply rooted in the Rajbanshi community to treat a variety of ailments. Though with due course of time, the availability of modern healthcare services improved, the community still continues to rely on traditional medicine, highlighting the importance of plants in the treatment of illnesses. The results of the survey illustrated the continued significance of traditional medicine in the lives of these indigenous people in the study area. The present study documented the ancient practice of traditional medicine by the Rajbanshi community of India. About 37 medicinal plants were documented that are used to treat inflammation and for healing different types of wounds by Rajbanshis. This study highlights the plants which are focused mainly to cure inflammation, inflammation-related disorders, and healing wounds. Though some of the plants were also used for treating different types of fevers, such as *Stephania japonica, Sida acuta, Ludwigia perennis,* and *Leucas zeylanica*. For treating diarrhoea, dysentery, and for stomach-related disorders *Stephania japonica*, *Cajanus cajan*, *Mikania micrantha*, *Centella asiatica*, and *Leucas zeylanica* are used. The community used several parts of plants for preparing the herbal formulations, starting from the entire plant to its leaves, stem, roots, buds, flowers, seeds, fruits, and bark. Leaves were used the most for preparing the herbal formulation. Different modes of application were preferred for treatment such as consuming the filtrate of the leaf, applying the paste on the wound/inflamed area, inhaling the smoke of burnt leaves, or simply consuming it as cooked vegetables. The herbal preparations were utilized mostly to heal wounds and sores, abdominal pain/ache, cure jaundice, liver problems, as well as for anti-parasitic activities. However, the traditional healers of Cooch Behar district have now inclined more towards treating bone-related problems, such as breaking or dislocation of bones, and arthritis.

Almost all living beings are subject to attack by foreign pathogenic agents. Our immune system plays the most important role in combating those foreign particles and acts as a barrier in establishing the infection induced by pathogens as well as non-pathogenic agents. The non-specific immune system acts as the primary barrier by releasing several mediators and recruiting immune cells at the target site for prompt response through inflammation. Whereas, the specific immune response is target specific which responds through antibody production or through cell-mediated immune response. Immunostimulatory agents from the plant world have the potential to activate the immunological responsiveness of an organism directly at the cell level or by inducing the production of mediators. Plants and plant-derived products are safer, eco-friendly, low-cost, fast, and less toxic as compared with conventional treatment methods and act specifically on target cells without affecting normal cells when administered in proper doses. It strengthens the overall activity of the immune system including those elements that are most capable of controlling inflammatory conditions. Thus, the present study has selected seven different plant species (*Ageratum conyzoides*, *Cenetella asiatica*, *Cajanus cajan*, *Mikania micrantha*, *Coccinia grandis*, *Cleome spinosa*, and *Drymaria diandra*) which were mainly used to cure inflammatory diseases and for healing different cuts and wounds by the Rajbanshi people. Ethanolic extracts of these seven different plants were evaluated for their anti-inflammatory and immunostimulatory properties. The purpose was to look for plants with immunopharmacological properties to cure inflammatory diseases in humans. Among the seven plants investigated, *Cleome spinosa* (CSE), *Cajanus cajan* (CAE), and *Drymaria diandra* (DDE) showed high immunopharmacological properties. They exhibited anti-oxidant and anti-inflammatory properties by scavenging free radical generation, alleviating deleterious DTH response, and healing the DTH wound faster. Knowing the fact that ROS generation is one of the crucial components in aggravating inflammation and causing tissue damage, a plant product that can scavenge ROS and at the same time minimize tissue damage induced by deleterious DTH reaction and heal the wound faster without any digit loss in the murine model could turn out to be a wonderful drug.

The HA titre results were quite fascinating as with CSE and CCE treatment, the antibody titre in the host serum increased several folds higher than the control groups upon antigenic challenge. This immunostimulatory property of *Cleome spinosa* and *Cajanus cajan* has been reported here for the first time. However, other plants such as *Ageratum conyzoides* (ACE), Centella asiatica *(CAE), Mikania micrantha* (MME), and *Dymaria diandra* (DDE) also exhibited similar properties but with lower effectivity. There are certain advantages of using plants to boost the immune system as they can be utilized directly as feed and can stimulate both systemic and mucosal immunity. Our study shows that ethanolic leaf extract *Cleome spinosa* and *Cajanus cajan* plant extract can stimulate the antibody-mediated immune system in a murine model when challenged with sheep RBC. There are several pathological conditions where the immunocompromized host shows more susceptibility towards infections due to certain environmental or genetic factors [11]. One such condition is severe combined immunodeficiency (SCID) disease where there is a deficit of both humoral and adaptive immune response leading to uncontrolled damage [8]. Immunodeficiency can also arise during treatment with various agents/drugs during malignancy or for allograft rejection, leading to secondary immunodeficiency, compromising the host defence mechanism. During immunosuppression induced by pathogens, a herbal compound that has the potential to activate the humoral arm of the immune system can prove to be a wonderful agent to induce antibody production to neutralize the pathogenic effect or binds with the antigen facilitating its destruction by other cells. Thus, it will be interesting to study in detail the immunopharmacological properties of *Cleome spinosa* and *Cajanus cajan* in the future with pathogenic challenges. At the same time, we also suggest that further research on *Cleome spinosa* (CSE), *Cajanus cajan* (CAE), and *Drymaria diandra* (DDE) might provide some important leads to the search for new drugs to cure pathogenic as well as non-pathogenic inflammatory diseases.

6 Conclusion

Globally, the use of medicinal plants is widespread in the developing world, providing primary health care, livelihood improvement, and even a source of income for many people. As a result, the importance of preserving and protecting these plants is of paramount importance for the continued health of both local communities and the global population. Studies have demonstrated that medicinal plants can offer a wide range of therapeutic benefits, from treating chronic and acute illnesses to improving overall wellness. Furthermore, medicinal plants can be used to enhance nutrition, reduce the use of synthetic drugs, and provide economic opportunities for communities. As a result, the conservation of medicinal plants is imperative to ensure that their medicinal properties are not lost. Moreover, research into the potential medicinal uses of plants is an important part of the health care industry. This research can help to identify new medicines, develop safer drugs, and improve the efficiency of existing medicines. Furthermore, the use of medicinal plants can also help to reduce the cost of health care, as many of these plants are readily available and do not require the use of expensive pharmaceuticals. In this study we have documented different ethnomedicinal plants which are mainly used by the Rajbanshi community. Through ethnobotanical studies, it is important to document the indigenous knowledge associated with the plants of a certain region. This knowledge can be used to help conserve and utilize the biological resources of the region, as well as to uncover potential bio-cultural benefits. In addition, the collection of local names and traditional uses of the plants can provide important insights into the culture of the indigenous people of the area.

Strategies related to drug discovery are taking a new turn by including the knowledge gained from traditional and alternative system of medicines. The world still holds enormous medicinal plants and still there are many indigenous ethnic communities that use plants as the important source of treatment. Both need to be explored extensively, for the development of new anti-inflammatory drugs, as a majority of the plant species have not been investigated for their potentiality to cure inflammatory disorders which are non-cytotoxic. Thus, learning from the indigenous communities about their age-old traditional treatment methods and implementing it for the betterment of the mankind is the need of the hour.

Acknowledgment The present work was financially supported by Science & Technology and Biotechnology, Govt. of West Bengal, India (Memo No. 342 (sanc.)-ST/P/S&T/16 G-27/2018). The authors acknowledge the Rajbanshi community who have shared their knowledge/information that enabled the authors to put forward a well-rounded perspective on the topic. The authors also show gratitude towards Mr. Jadu Saud for assisting during the field survey.

Plants Used in the Management and Treatment of Cardiovascular Diseases: Case Study of the Benin People of Southern Nigeria

30

Matthew Chidozie Ogwu, Happiness Isioma Ogwu, and Enoch Akwasi Kosoe

Contents

Abstract

There is a global increase in cardiovascular diseases (like stroke, heart attack, and heart failure), especially in developing countries. Healthcare organizations in these low- and middle-income countries are unable to handle the current and projected economic and social effects of CDVDs and are struggling to deal with other diseases and developmental challenges that disproportionately impact the region. This chapter aims to produce an inventory of plants and plant-based remedies used by Benin people, Nigeria, for the treatment and management of CDVDs. Fourteen locally identifiable key informants including professional

herbalists, traditional healers, and herbal remedy sellers were administered questionnaires to document plants and plant-based remedies used in the management and treatment of CDVD by Benin people of Southern Nigeria. From the survey, a total of 17 medicinal plants belonging to 14 plant families were identified, documented, and collected as used by Benin people for the treatment and management of CDVD. The plants included *Theobroma cacao, Aloe barbadensis, Momordica charantia, Laurus nobilis, Morinda citrifolia, Carica papaya, Allium cepa, Ficus exasperate, Elaeis guineensis, Olea europaea, Persea Americana, Moringa oleifera, Beta vulgaris, Allium sativa, Hunteria umbellate, Zingiber officinale,* and *Curcuma* species. The dominant plant families were Lauraceae, Amarylidaceae, and Zingiberaceae with two representatives each. The plants were mostly collected from home gardens, markets, and local forests and within either cultivated or wild systems. Although plants and plant-based remedies were mostly taken to address hypertension and high blood pressure, they are also used to manage stroke and to address CDVD-related chest pains without any side effects. Medicinal plants used in the management and treatment of CDVD contain natural bioactive compounds that accumulate in the plants as secondary metabolites, such as alkaloids, sterols, terpenes, flavonoids, saponins, glycosides, and tannins. The fundamental problem that most herbal medications address is the lack of standardization that may be used to classify them even though these effects usually overlap.

1 Introduction

There has been a considerable rise in cases of cardiovascular diseases globally [222]. CDVD is now considered among the principal cause of mortality globally. The incidences of diseases are rising at an alarming rate, especially in developing countries [102, 138, 149]. CDVD refers to any disease of the heart and blood vessels [102]. Also, cardiovascular disease was defined by Abunnaja and Sanchez [3] as "the pathologic process (usually atherosclerosis) affecting the entire arterial circulation, not just the coronary arteries" [3]. The most common CDVDs are cardiomyopathy, aortic disease, hypertension, strokes, coronary heart disease, high blood pressure, heart attack and failure, and peripheral arterial disease [102, 108, 125, 244]. CDVD causes economic, sociocultural, and health burdens to societies globally and accounts for around 31% of deaths every year [199, 236]. Globally, the World Health Organization (WHO) estimates that cardiovascular disease claims about 17.9 million lives [19, 42, 65, 122, 138, 199].

Healthcare organizations in low- and middle-income countries are unable to handle the current and projected economic and social effects of CDVDs, and the economic burden on high-income countries is unsustainable [116]. The CDVD crisis has increased the strain on the healthcare systems of sub-Saharan African (SSA) nations, which are already trying to deal with other diseases and developmental challenges that disproportionately impact the region [78, 85, 135, 139, 141, 145, 166, 183]. Also, information about region and age-specific death from CDVDs suggests SSA is disproportionately affected and so are people above 45 years [59, 227, 239]. Some causes of CDVD include unhealthy habits like smoking, and others like high cholesterol, hypertension, obesity, excess inactivity, and diabetes mellitus [149]. By 2025, the United Nations (UN) wants to reduce fatalities from noncommunicable diseases including cardiovascular disease by 25%. The current therapeutic approaches' economic costs to lower the three main CDVD risk factors – hyperlipidaemia, atherosclerosis, and hypertension – cannot be sustained on a worldwide scale [116].

Regarding the treatment of CDVD in SSA, herbal therapy is the most preferred healthcare for those affected but is also often complemented with modern medicines. It is arguably so because of sociocultural and economic motivations like affordability, availability, self-medication, and history of successful use in traditional communities [87, 128]. Herbal therapy for CDVD in SSA mostly revolves around the use of medicinal plants and spirituality because of their fewer side effects, reliability, accessibility, availability, and ability to self-medicate. Moreover, modern medicine is considered by some native people to be ineffective in the treatment and management of certain disease conditions [175]. Herbal medicines refer to the use of plant parts, materials, extracts, preparations, and products either alone or their combinations to address diverse medical uses [81, 128, 140, 143, 144, 146, 147]. Traditional medicine is a common healthcare means in developing countries of the Global South, whereas complementary or alternative medicine refers to modern medicine used in developed nations [33]. The use of traditional medicine in SSA and other parts of the Global South is often attributed to their accessibility, effectiveness, familiarity, perceived safety, naturalness, cost friendliness, and culture [29, 49, 127, 134, 178, 209].

This chapter aims to produce an inventory of the plant and plant-based remedies used by Benin people, Nigeria, for the treatment and management of CDVDs. A focused approach was adopted to select informants along with a non-experimental validation of the plants used through a literature review of the phytochemical and pharmacological information supporting the medicinal activities of the plants and plant-based remedies used in the treatment and management of CDVDs. Also, this chapter documents the traditional medicinal practices for the treatment and management of cardiovascular diseases and enumerated how these plants are used (i.e., either alone or in combination).

2 Plants and Plant-Based Remedies for the Treatment and Management of Cardiovascular Diseases in Benin City, Southern Nigeria

A survey was carried out in the six Local Government Areas that make up Benin City, Edo State (6.34° N and 5.60° E; Fig. 1) and occupied by Benin people of Southern Nigeria to document medicinal plants and traditional plant-based remedies used in the treatment and management of CDVDs. Benin City lies within the humid tropical rainforest zone of Nigeria but its vegetation has been heavily altered by

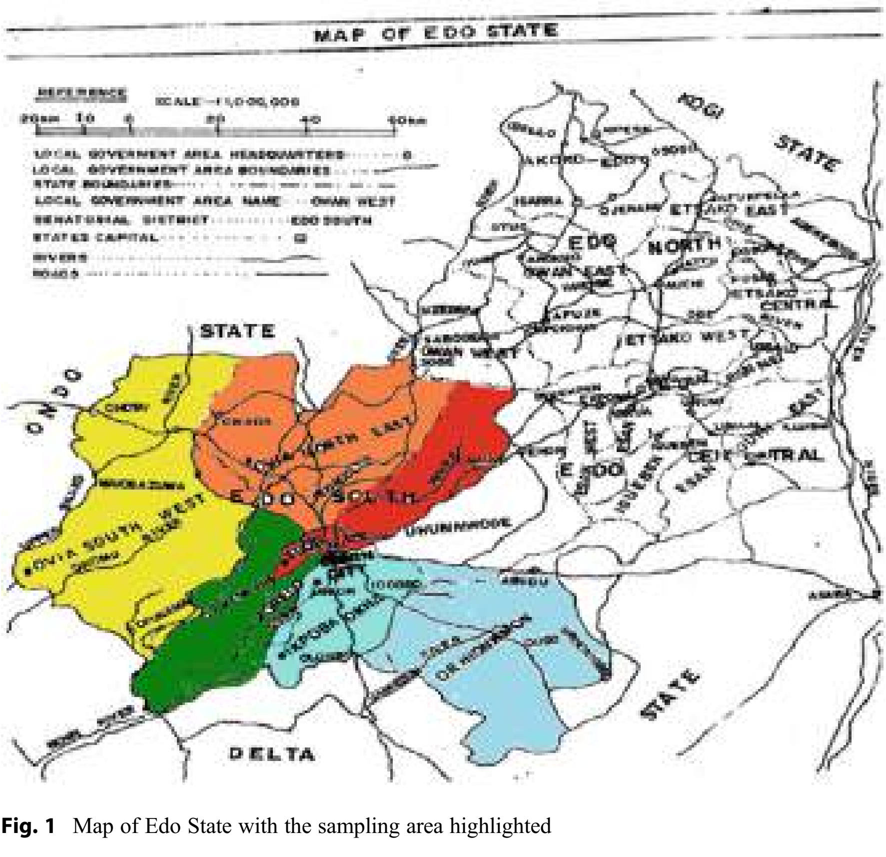

Fig. 1 Map of Edo State with the sampling area highlighted

anthropogenic activities and human population growth and is currently a mosaic of secondary forest [161–163]. The climate is monsoonal with two distinct seasons (dry and rainy season) with high rainfall (2000–3000 mm), temperature (20–40 °C), and average atmospheric humidity of 28% and with radiation of 1600 h per year [150, 152]. A detailed description of the geography, biodiversity, and soil features of the study area is present in Osawaru et al. [155–160], Osawaru and Ogwu [153, 154], Ogwu and Osawaru [142].

The survey to document traditional medicine practices and higher plants used for managing and treating CDVD by Benin people was conducted between January and June 2021 using survey sheets for information collection, a digital camera, an audio recording device for interviews, and a mobile phone-enabled position marker. The survey focused on randomly selected and locally identifiable professional herbalists, traditional healers, and herbal remedy sellers using semi-structured, open-ended questionnaires in English and/or preferred native languages. The 14 randomly selected respondents and interviewees are duly registered with all the relevant authorities (Table 1). The questionnaires were administered to the key informants (full-time traditional healers, part-time practitioners, elderly people who know the

traditional values of the plants, relatives, and acquaintances who at one time or the other used some of these plants for the treatment and management of CDVD). The respondents animated a field survey to identify and collect plants and plant parts used for the treatment and management of CDVD. Specific information about the plants like their botanical and local names, part of the plant used, method of preparation and dosage, application, and treatment duration were asked and recorded. Collections were made from homestead farms, distant farms, and different forests present in the study area.

Data collected include the socio-demographic features of the survey respondents (e.g., marital status, educational level, employment status, gender, occupation, and tribe/ethnicity). Other pertinent data collected included plants used for CDVD treatment and/or management and preparation of the herbal remedies. Data collected were processed and analysed using Windows Microsoft Excel 2016 version software to understand inherent patterns. The therapeutic relevance of each identified species was also recorded. Based on the knowledge of the informants, a total of 17 medicinal higher plant species that are used for the treatment and management of CDVD were identified by a taxonomist at the University of Benin, Nigeria, and documented.

2.1 Medicinal Plants and Plant-Based Remedies Used by Benin People for the Treatment and Management of Cardiovascular Diseases

From the survey, a total of 17 medicinal plants belonging to 14 plant families were identified, documented, and collected as used by Benin people for the treatment and management of CDVD (Tables 2 and 3). The plants included *Theobroma cacao, Aloe barbadensis, Momordica charantia, Laurus nobilis, Morinda citrifolia, Carica papaya, Allium cepa, Ficus exasperate, Elaeis guineensis, Olea europaea, Persea Americana, Moringa oleifera, Beta vulgaris, Allium sativa, Hunteria umbellate, Zingiber officinale,* and *Curcuma* species. Some of these plants including *Allium sativum*, *Persea americana*, *Hunteria umbellate, Moringa oleifera*, and *Allium cepa* have been previously documented as useful for managing and treating CDVD [138]. The dominant plant families are Lauraceae, Amaryllidaceae, and Zingiberaceae with two representatives each. The other plant families are Malvaceae, Liliaceae, Cucurbitaceae, Rubiaceae, Caricaceae, Moraceae, Apocynaceae, Arecaceae, Moringaceae, Oleaceae, and Amaranthaceae. The habitat of these plants ranges from evergreen rainforests to warm temperate zone (Table 2). The plants were mostly collected from home gardens, markets, and local forests and within either cultivated or wild systems (Table 3). Earlier, Osawaru and Ogwu [154] confirmed the presence of plants with herbal medicine value as well as plant-based herbal remedies in local markets in Benin City and its environs. The plants and plant-based remedies were taken to address the following CDVDs – stroke, high blood pressure, hypertension, and chest pains without any side effects. It is known that plants are used to treat people with CDVDs like heart attacks, hypertension, cerebrovascular disorder, and heart failure [95, 126, 138]. Although these plants and

Table 2 Ethnobotanical documentation of plants and plant-based remedies used in the treatment and management of cardiovascular disorders

Plant and Plant-Based Remedy						
Plant name	Scientific name	Usefulness	Plant Family	Plant Habitat and Origin	Efficacy	Known Side Effects
Cocoa and Aloe Vera	*Theobroma cacao* *Aloe barbadensis*	Stroke and high blood pressure	Malvaceae Liliaceae	Evergreen tropical rainforest Tropical/subtropical forest (xerophytic environment)	Successful	None
Bitter melon/ bitter squash	*Momordica charantia*	High blood pressure	Cucurbitaceae	Terrestrial	Successful	None
Bay leaf	*Laurus nobilis*	High blood pressure	Lauraceae	Mediterranean area	Successful	None
Indian mulberry or hog apple	*Morinda citrifolia*	High blood pressure	Rubiaceae	Shady forests	Successful	None
Pawpaw	*Carica papaya*	High blood pressure	Caricaceae	Tropics of America	Successful	None
Onions	*Allium cepa*	Hypertension	Amaryllidaceae	Temperate zone	Successful	None
Sandpaper plant	*Ficus exasperata*	Hypertension	Moraceae	Moist deciduous Fringe Forest	Successful	None
Garlic, ginger, and turmeric	*Allium sativa* *Zingiber officinale* and *Curcuma* species	Hypertension	Amaryllidaceae Zingiberaceae	Terrestrial	Successful	None
Abeere	*Hunteria umbellata*	Hypertension	Apocynaceae	Terrestrial	Successful	None
Palm kernel nut Moringa seed	*Elaeis guineensis* *Moringa oleifera*	Stroke	Arecaceae Moringaceae	Tropical or subtropical region	Successful	None
Olive seed	*Olea europaea*	High blood pressure	Oleaceae	Mediterranean basin	Successful	None
Avocado pear	*Persea americana*	Chest pain	Lauraceae	Tropical/temperate region	Successful	None
Beetroot	*Beta vulgaris*	Hypertension	Amaranthaceae	Warm temperate zone	Successful	Yes, not to be taken with malaria medication

Table 3 Primary usage or methods of using these plants for treatment and management of cardiovascular disorders

Plant Remedy	Parts Used	Methods of Administration	Duration of Use	When Used	Dosage	Storage Method	Source of Plant	Wild or Cultivated	Collection Time
Cocoa Aloe Vera	Leaves and seeds	Infusion	Until recovery	Morning and evening	2 teaspoons	Canning	Garden and forest	Cultivated	Anytime
Bitter melon	Fruits and seeds	Aqueous steeping	Daily	Morning and evening	A glass	Freezing	Market and garden	Cultivated	Anytime
Bay leaf	Leaves	Aqueous steeping	Daily	Morning and evening	A glass	Bare floor or dry place	Market	Cultivated	Anytime
Indian Mulberry	Fruits and seeds	Aqueous steeping	Daily		25 ounces	Freezing	Garden	Cultivated	Anytime
Pawpaw	Fruits	Aqueous steeping	Daily	All the time	2–3 glasses	Freezing	Garden and market	Cultivated	Anytime
Onions	Whole bulb and bulb peels	Aqueous steeping	Daily	All the time	As many as possible	Freezing	Market	Cultivated	Anytime
Sandpaper plant	Leaves	Aqueous steeping	Daily	3 times daily	NR	Freezing	Garden	Wild	Anytime

Avocado pear	Seed	Raw	1 week	Once daily	2 tablespoons	NR	Market	Cultivated	Anytime
Beetroot	Fruit and seed	Oral	Until recovery	Morning	1 bottle	Freezing	Market	Imported	Morning

NR Not reported

their herbal remedies have active substances with pharmacological and prophylactic properties, they often have little to no side effects when taken in moderation. These bioactive compounds include phenolics, flavonoids, nitrogen, anti-inflammatory, terpenoids, antioxidants, and other secondary metabolic compounds. Other researchers [26, 101, 199] have documented and confirmed the in vitro and in vivo efficacy of *Ginseng*, *Ginkgo biloba*, *Gastrodia elata,* Nerium *oleander*, Salvia *miltiorrhiza*, *Dracocephalum moldavica, Daucus carota*, *Ganoderma lucidum*, *Tinospora cordifolia*, *Hydrocotyle asiatica, Bombax ceiba, Terminalia arjuna*, *Amaranthus viridis, Andrographis paniculate, Mucuna pruriens*, *Picrorhiza kurroa*, and *Gynostemma pentaphyllum in the treatment and management of CDVD.* The consumption or use of these plants reduces the risk of CDVDs like congestive heart failure, hypertension, ischaemic heart disease, and arrhythmias [96, 99, 127, 138, 179, 186].

2.2 Enumeration of Plants Used in the Management and Treatment of Cardiovascular Disease by Benin People in Southern Nigeria

2.2.1 Cocoa (*Theobroma cacao*)

The use of cocoa in traditional medicine is linked to the phytochemical constituents in the plants like flavanol, polyphenol, and procyanidin in significant concentrations [25, 41, 197]. These compounds have nutritional and pharmacological benefits. The polyphenols in cocoa have cardiovascular-protective properties by modulating different inflammatory markers connected to atherosclerosis [99]. The flavanol in cocoa also has a regulatory capacity and helps with total dietary requirements [99, 109, 229]. Cocoa consumption has been linked to flow-mediated vascular dilatation, blood pressure, total lipid profiles, and insulin resistance [74, 75, 88, 184].

Also, methylxanthines have been reported from cocoa extracts and like theobromine and caffeine help enhance the vascular and central nervous system and work in tandem with flavonols and other secondary metabolic compounds [151, 194, 197]. Both procyanidins and flavanols have been connected to diverse cardiometabolic and cardiovascular advantages in humans through the improvements of endothelium-dependent vasodilation, blood pressure regulation, inflammation, and platelet activation [40, 46, 63, 73, 75, 103, 115, 119, 165, 176, 181, 185, 188, 193, 195, 197, 214]. Also, it provides insight into the distribution, absorption, metabolism, and excretion of flavonols [5, 164, 187].

2.2.2 Aloe Vera (*Aloe barbadensis*)

Aloe vera is an important tradomedicinal plant and its innermost leaf layer contains diverse minerals and secondary metabolites [190, 200]. Aloe is used as medicine by diverse cultures and societies globally worldwide since time immemorial [105]. Aloe vera leaves contain high amounts of anthraquinone [200]. The inner layer leaf of Aloe vera is called Aloe vera gel (AVG) or aloe gel and it does not contain those essential anthraquinone compounds [190]. The plant has several beneficial properties including those lipid-lowering, immunomodulatory effects, antioxidant, anti-inflammatory, and hepatoprotective effects [190, 200]. Aloe vera contains polysaccharides like acetylated polymannan, glucomannan, acemannan, and mannose-6-phosphate that have therapeutic and pharmacological effects. AVG has direct and indirect cardioprotective impacts through hyperglycaemia, hyperlipidaemia, hypertension, and obesity effects [190]. The mineral nutrients in AVG (like iron, zinc, copper, and selenium) also participate in enzymatic, cell metabolic, and antioxidant functions with net positive effects on CDVD. Also, AVG contains a lot of antioxidant vitamins which have been linked to decreased serum levels of and risk of coronary heart disease. Both lophenol and cycloartenol are present in aloe and they can regulate blood glucose [200].

2.2.3 Bitter Melon (*Momordica charantia*)

Bitter melon offers diverse health advantages for reducing illnesses and enhancing life [191]. It is grown in most countries with tropical or sub-tropical climates and popular medicinal food in many developing countries [219]. Bitter melon's whole fruit, seeds, and leaves control oxidative stress and prevent fat build-up, and contain a variety of bioactive substances, including alkaloids, polypeptides, vitamins, and minerals. It aids in controlling blood cholesterol levels, and defending the body against cardiovascular diseases like atherosclerosis [22, 191, 203]. Also, bitter melon improves glucose and lipid metabolism [35, 208, 218]. The medicinal benefits of bitter melon are linked to its high antioxidant qualities, which are partly owing to the presence of secondary phytochemicals like isoflavones, phenols, flavonoids, anthroquinones, terpenes, and glucosinolates that give the fruit its bitter flavour [17, 47, 64]. Loss of potential health benefits may occur when active bitter components are removed by a variety of debittering techniques and selective breeding [207]. Bitter melon contains vitamins, minerals, and flavonoids [17, 117]. Because it contains a variety of bioactive components, bitter melon exhibits pharmacological effects that have been linked to improved health, including the ability to scavenge free radicals and have hypoglycaemic and hypolipidemic effects [191, 230].

2.2.4 Bay Leaf (*Laurus nobilis*)

Bay leaf can be used in alternative medicine and is effective as a blood pressure-lowering medication [14, 54, 71]. Bay leaf consumption decreases CDVD risks [98]. This plant has a track record for effectively treating disease, has few adverse effects, and is accessible. Bay leaves contain tannins, flavonoids, citrate, eugenol, and essential oils [98, 215]. Antioxidant chemicals, which include tannins and flavonoids, are present in bay leaves and have health benefits regarding blood pressure [54, 98]. The availability and prevalence of bay leaf are anticipated to aid in spreading awareness and promoting it as a herbal alternative for health. Bay leaf is a plant that is often used in the neighbourhood as a complementary medicine. It is a diuretic and has been used to treat eructation, epigastric bloating, poor digestion, and flatulence [70]. In addition to its hypoglycaemic benefits, bay leaf can improve diabetic patients' capillary function, lipid metabolism, liver, and kidney function, as well as their antioxidant status [51, 69]. The glucosidase enzyme reduces blood sugar levels, and the phenolic chemicals in bay leaves could block it [94]. The bay leaf extract may cause pancreatic cells to secrete more insulin or that it acts similarly to insulin [221]. The fact that these extracts diminish gluconeogenesis and glycogenolysis, decrease glucose absorption, and improve peripheral glucose utilization also suggests that they may have hypoglycaemic effects [51, 170].

2.2.5 Indian Mulberry (*Morinda citrifolia*)

Indian mulberry is one of the main components in several traditional formulas that are sold all over the world [53]. Mulberries and their extracts are used to treat both acute and chronic illnesses because they have powerful antimicrobial, anti-hyperlipidaemic, anti-inflammatory, and anti-cancer properties [238]. The mulberry roots, bark, leaves, fruits, and stem twigs are rich sources of vital bioactive compounds [53, 93, 167, 238]. Mulberries are a great source of phosphorus, iron, riboflavin, calcium, vitamin (C and K), potassium, and other essential minerals for our bodies [13, 93]. Additionally, they contain a sizable amount of dietary fibre as well as a variety of organic substances, such as phytonutrients, zeaxanthin, resveratrol, anthocyanins, lutein, and different polyphenolic compounds [93]. This plant's extraordinary benefits in decreasing blood cholesterol and serum glucose levels make it possible to utilize them. The presence of numerous bioactive components in this plant, including flavonoids, polyphenols, alkaloids, terpenoids, and steroids, is what gives it these qualities [93].

2.2.6 Pawpaw (*Carica papaya*)

Pawpaw has high dietary fibre, protein, carbohydrates, vitamins, and mineral nutrients. The plant is used to address diverse ailments including for treating indigestion and gastric ulcer. The consumption of pawpaw fruit helps reduce blood pressure [52, 169]. It offers numerous health advantages, including lowering blood pressure, promoting wound healing, assisting with digestion, lowering the risk of heart disease, diabetes, and cancer, and enhancing blood glucose control in diabetics [4]. Pawpaw seeds and fruits have potent antihelminthic and antiamoebic properties [11, 148]. Ascorbic acid, flavonoids, cyanogenic glucosides, and glucosinolates are just a few of the active substances found in pawpaw leaves that have been shown to lower lipid peroxidation levels and increase total antioxidant power in the blood, thus they can be used either for the prevention or treatment of CDVD [11, 196, 202].

2.2.7 Onions (*Allium cepa*)

Onions are regarded as essential vegetables [20, 30, 76, 83, 220]. Many cultures have valued onions for their culinary and therapeutic uses because they are rich sources of flavonols and organosulfur compounds [66, 131]. Also, it contains flavonoids and phenolics which have antioxidant, anti-cholesterol, anti--inflammatory, and anticancer properties. The plant is rich in protein, water, selenium, and different vitamins (B1, B2, and C) as well as potassium, diverse polysaccharides, and essential oil [225]. These phytochemicals have been linked to several health advantages and improvement in diseased conditions [20, 30, 76, 83, 86, 112, 220]. The variety of phytonutrients in onions is known to have important and extensive biological activity. Onions exhibit potent anti-atherogenic effects that are related to a variety of bioactivities [86, 112, 220]. The high amounts of flavonoids and organosulfur compounds are linked to these biological actions, which are mostly antioxidant and anti-inflammatory in nature [30, 220, 225, 235].

2.2.8 Sandpaper Plant (*Ficus exasperate*)

Sandpaper plant is a deciduous shrub or tree and extracts from the leaf have demonstrated high concentrations of secondary phytochemicals like alkaloids, tannins, flavonoids, and saponins [237]. It has been used to treat difficult childbirth, bleeding, and diarrhoea. Sandpaper leaf has hypoglycaemic potential and is utilized to manage, regulate, and/or treat CDVDs like hypertension. The leaf extract is used to treat cardiac problems and reduce blood pressure [10, 38]. Also, in the treatment of numerous degenerative diseases, the bark, leaves, fruits, and latex of sandpaper plants contain astringent, anti-oxidative, carminative, anti-inflammatory, and anticancer agents that can be used to treat diabetes, skin conditions, ulcers, dysentery, diarrhoea, stomach aches, haemorrhoids, and hypertension [12, 38, 91]. The plant's ability to treat or manage several ailments is supported by the presence of phytochemicals. Its high quantities of flavonoids and saponins, however, imply that taking the plant in excessive doses over a sustained period can cause toxicity [237].

2.2.9 Garlic (*Allium sativa*)

Garlic, the most popular herbal dietary supplement on the market, is famous for its vast health benefits, especially in the treatment and prevention of CDVDs [16, 80]. It has a lot of sulphur-based compounds and is a good source of carbohydrates as well as proteins [2, 80, 233]. More than 200 unique compounds that can shield the human body from a wide range of ailments can be found in garlic alone. Garlic's sulphur-containing components provide the body with protection by promoting the development of specific advantageous enzymes [60, 120]. Garlic contains sulphur compounds, and diverse enzymes, as well as essential minerals (like calcium, germanium, iron, copper, magnesium, potassium, zinc, and selenium), vitamins (A, B1, and C), fibre, and water [60]. Also, garlic extracts exhibit anti-inflammatory, antioxidant, and anti-microbial properties [110, 204, 234]. The consumption of garlic helps lower blood pressure, total cholesterol, body mass index, triglycerides, and inflammatory indicators [28, 34, 60, 80, 210]. Additionally, it can raise HDL-c levels and enhance several cardiovascular parameters, including carotid intima-media thickness, microcirculation, post-occlusive reactive hyperaemia, epicardial and periaortic adipose tissue, and low attenuation plaque [60, 80].

2.2.10 Ginger (*Zingiber officinale*)

Ginger is rich in antioxidant and anti-inflammatory compounds [124, 243]. Some of these compounds are effective against CDVD like hypertension and other diseases [18, 189]. The phenolic compounds in ginger include gingerols, paradol, and shogaol that have therapeutic and pharmacological potentials and are helpful in the management of inflammatory and oxidative stress diseases [114, 132, 189, 212]. In addition to its significant nutritional contributions, ginger has several medicinal and immune-boosting benefits. Additionally, they are crucial in the control of blood pressure and the treatment of cardiovascular diseases. The utilization of ginger-based products will help to advance the human health system [48, 82, 104, 114, 130].

2.2.11 Turmeric (*Curcuma* species)

Turmeric has spiritual significance and uses to treat various CDVDs and other diseases such as digestive, respiratory, and hepatic illnesses or disorders [9, 100, 106, 129, 171, 172, 192, 228]. Having a low bioavailability and pleiotropic activity, turmeric is a naturally occurring phenolic compound. Turmeric has been used as a cooking spice and a traditional treatment to heal skin conditions, cuts, and wounds since the dawn of time [92, 198]. It has been recognized as an essential dietary supplement and nutraceutical [72, 206]. There is evidence that the primary yellow bioactive component of turmeric has a variety of biological effects. These consist of its antioxidant, anti-inflammatory, anti-mutagenic, anti-carcinogenic, anti-coagulant, antifertility, antidiabetic, antibacterial, anti-fungal, anti-viral, anti-fibrotic, anti-venom, anti-ulcer, hypotensive, and hypocholesterolaemic activities [92, 192, 198, 228].

2.2.12 Moringa (*Moringa oleifera*)

Moringa tree is common in Asia and Africa and is appreciated for its therapeutic properties as the "miracle tree" [8, 19, 97, 111]. It has traditionally been utilized as both a food source and a medication to treat several illnesses like anaemia, diabetes, and infectious or cardiovascular ailments [1, 19, 62, 216]. The biggest medicinal and nutritional benefits are found in the leaves and seeds of the moringa plant. Protein, minerals, and antioxidant chemicals are plentiful in the leaves [19, 27, 77, 111]. In addition to being nutrient-rich, moringa also has anti-nutrients such as flavonoids that function as antioxidants [211, 223]. The primary phytochemical components of moringa are phenolic acids, flavonoids, saponin, tannins, alkaloids, glycosides, and glucosinolates [31, 32, 168, 226]. The bioactive components in moringa have synergistic therapeutic effects that include lowering blood sugar levels, anti-inflammatory properties, cardioprotective, anticancer, antimicrobial, neuroprotective, and immune system modulation [118, 223]. The phytochemicals N,L-rhamnopyranosyl vincosamide, isoquercetin, quercetin, quercitrin, and isothiocyanate that have been linked to functional activities related to cardiovascular disorders have been found in Moringa. The phytochemicals, such as quercetin and N,L-rhamnopyranosyl vincosamide, have molecular antioxidant, anti-inflammatory, and anti-apoptotic properties. These result in increased cardiac contractility and damage prevention for the heart's structural integrity. Additionally, these substances function as endothelium protectors and natural vasorelaxants [19, 113, 213].

2.2.13 Olive (*Olea europaea*)

Olive tree is considered one of the oldest tree species, and historically, indigenous inhabitants relied on its fruits and by-products, such as olive oil, as their primary source of nutrition [56, 67, 241]. Olives are a good source of vitamins, minerals, and carbohydrates. Numerous studies have found links between the "Mediterranean diet's" health advantages and longer life spans and lower occurrences of chronic degenerative diseases [67]. Olive leaf polyphenols and flavonoids have been shown to have anti-inflammatory, anti-carcinogenic, anti-hypertension, and antibacterial characteristics; they are therefore crucial to the outcomes that have made olive leaves significant. Olive leaves contain secoiridoid phenols, which are unique to the plant [217].

Olive seed protein hydrolysates have been shown to exhibit significant antioxidant and angiotensin-converting enzyme (ACE) inhibitor capabilities and to lower micellar cholesterol solubility [57]. Also, olive leaf extract (OLE) has lipid-lowering properties and contains significant amounts of the phenolic antioxidant known as oleuropein, far more than what is found in olive fruit or olive oil [21, 58, 68, 173, 205]. Olive oil contains at least 30 phenolic compounds, the majority of which are simple phenols (tyrosol and hydroxytyrosol), secoroids (oleuropein and ligstroside), and lignans (1-acetoxypinoresinol and pinoresinol) [42, 224]. The phenols in olive oil include straightforward compounds like vanillic, gallic, coumaric, caffeic acids, tyrosol, and hydroxytyrosol [224]. In several populations, phenolic compounds from virgin olive oil have had a positive impact on systolic and diastolic blood pressure [42, 121, 201]. A large amount of monounsaturated fat and a low amount of saturated fat are two of olive oil's key qualities. The primary monounsaturated fat, oleic acid, has several health-improving qualities, including a decrease in CDVD, neurological disorders, and cancer. Virgin olive oil is also rich in several beneficial compounds and polyphenols are likely the most important of these bioactive chemicals [42, 232]. Olive oil's phenolic components are extensively researched for their antioxidant capacity [67, 241]. It was discovered that several phenols from olive oil (like hydroxytyrosol and oleuropein) operate as radical scavengers and diminish the production of superoxide anions, neutrophil respiratory bursts, and hypochlorous acid. This may account for the decreased incidence of cancer and coronary heart disease that has been linked to the Mediterranean diet [42, 67, 231, 241]. Olive oil is resistant to heat oxidation and possesses high antioxidant potential within biological systems [42, 201, 241, 242]. Tocopherols and phenols are the principal substances enhancing stability during heat oxidation. The stability is also aided by the oil's high oleic acid content [67, 241].

2.2.14 Avocado (*Persea americana*)

The avocado pear is a widely grown and popular tropical fruit that is eaten all over the world [23, 36]. It also has significant levels of protein, potassium, and unsaturated fatty acids, which are uncommon in other fruits [23]. Its oil is high in monounsaturated fatty acids and is utilized to boost high- and low-density lipoprotein levels [137]. The chemicals included in the lipidic component of this fruit, including omega fatty acids, phytosterols, tocopherols, and squalene, have been credited with its health advantages. The health benefits of avocados include lowering cholesterol and avoiding cardiovascular illnesses [23, 137, 177]. This tree has been known to possess several therapeutic characteristics, including emmenagogue (fruit) and cicatrizant (fruit pulp). Its leaves have also been used to treat digestive disorders and skin infections and irritation. Additionally, seed oil has long been used as an ointment to soothe pain and soften the skin around wounds, as well as for the treatment of dry hair and other diseases [39, 137]. The primary bioactive substances found in avocado include tocopherols, carotenoids, polyphenols, and phytosterols. While carotenoids and tocopherols are primarily present in the avocado pulp, polyphenols can be found in the fruit's pulp, peel, seed, and leaves. Waste extracts, therefore, have a variety of biological properties, such as antimicrobial, anticancer, anti-inflammatory, antidiabetic, and antihypertensive properties [15, 89, 107, 137, 177].

2.2.15 Beetroot (*Beta vulgaris*)

Beetroot is grown in many nations throughout the world. It is consumed as part of a normal diet and is frequently used in food processing as a food colouring ingredient [37, 61, 245]. Proteins, sugar, carbs, vitamins (B complex and vitamin C), minerals, and fibre are all found in abundance in beetroot. The phenolic chemicals and antioxidants in beet include sesquiterpenoids, coumarins, triterpenes, carotenoids, and flavonoids (rhamnocitrin, tiliroside, kaempferol, astragalin, and rhamnetin) and are also present in significant amounts [37, 174]. Beetroot contains antioxidant and anti-inflammatory effects, anti-carcinogenic and anti-diabetic activities, as well as hepato-protective, hypotensive, and wound healing capabilities [37, 43, 61, 123]. Bioactive substances like dietary NO_3, betanin, antioxidants, and phenolic compounds are found in beetroot. Beetroot contains a variety of additional bioactive chemicals that may have health advantages, especially for conditions marked by chronic inflammation [37]. By enhancing nitric oxide synthesis, controlling gene expression, or modulating the activities of proteins and enzymes involved in these cellular processes, beetroot rich in nitrate and bioactive compound contents improves cardiovascular and metabolic functions [37, 45, 240]. The body uses nitric oxide (NO) for vasodilation to lower blood pressure and improve nutrients and oxygen supply within the body. According to these outcomes, beetroots may be useful in the prevention and treatment of cardiovascular disease [24, 90, 123, 180, 182, 240]. The beetroot-cereal bar exhibits high levels of antioxidant, phenolic, and nitrate components. A beetroot-cereal bar might be a good way to help individuals who have risk factors for cardiovascular disease by improving their cardiovascular parameters [44].

2.2.16 Palm Kernel Nut (*Elaeis guineensis*)

Contrary to common belief, the excess consumption of palm kernel oil does not increase the risk of having CDVD. The work of Ismail et al. [84] could not find any association but recommend their consumption in moderation to ensure good cardiometabolic health. Oil palm is abundant in West Africa and is the chief source of cooking oil [79]. Although it contains about 50% saturated fatty acid and high amounts of unsaturated fatty acids, it is not known to promote either arterial thrombosis or atherosclerosis [50]. Rather it has been documented that oil palm phenolic (OPP) found in oil palm has cardioprotective effects through mechanisms and pathways such as cholesterol biosynthesis pathway, anti-inflammatory properties, and antioxidants. OPP is recoverable from oil palm milling aqueous waste products. The CDVD effects of oil palm extolled by Benin people might likely be linked to OPP and other properties of the plant fruits.

2.2.17 Abeere (*Hunteria umbellata*)

Abeere is widely used in traditional medicine in SSA for CDVD as well as managing and treating sexually transmitted diseases, anaemia, obesity, diabetes, and stomach ulcers. The plant can be found in tropical forests all over SSA. The medical benefits of the plant are linked to its phytochemical compositions which include tannins, alkaloids, flavonoids, phenolics, and saponins, which have been implicated in lipid peroxidation, antioxidant, and free-radical scavenging activities [7, 55]. Recently, Odukoya et al. [138] implicated the use of the seed, stem, and bark of the plant in the treatment and management of CDVD. These parts of the plants contain diverse water-soluble alkaloids. It is likely that the nitric oxide synthase and arginase inhibitory effects on endothelial function contribute to the CDVD roles of the plant [136]. Another consideration is that the alkaloid fraction of *H. umbellata* helps to reduce weight gain, which otherwise may increase the risk of CDVD [6]. Hence, *H. umbellata* has a cardioprotective effect by contributing to weight loss.

3 Conclusion

Since time immemorial, plants have been used in the treatment of diverse CDVDs and recent epidemiological research has shown that eating foods derived from certain plants lowers the chance of developing cardiovascular disease. These plants will continue to play significant roles in sustaining human societal and individual well-being. Medicinal plants used in the management and treatment of CDVD contain natural bioactive compounds that accumulate in the plants as secondary metabolites, such as terpenes, flavonoids, alkaloids, sterols, glycosides, saponins, and tannins. These compounds have both therapeutic properties and pharmacological effects on humans. Traditional remedies have been utilized to treat cardiovascular illnesses for a very long time but have only started to attract the interests of researchers, government agencies, and large co-operations as they seek to explore alternative medicine, promote their usage, and search for natural raw materials and remedies for illnesses of global concern like CDVD. The fundamental problem that most herbal medications address is the lack of standardization that may be used to classify them even though these effects usually overlap. The chemical constituents of medicinal plants used for managing and treating CDVD should be further explored as potential raw materials for modern medicine as well as to understand their mode of action to improve the quality of life for individuals and society in general. Strong cardioactive glycosides are present in several plants, and they have favourable inotropic effects on the heart. The advantages of plant-based diets for the prevention of CDVD need to be investigated further. The phytochemical components found in natural goods are being researched for their potential to shield the cardiovascular and vascular systems from further harm.

Abstract

The intake of flowers as food is documented in a variety of cultures as part of customary dishes and alternative therapies. But numerous types of edible flowers are more than just a treat because they include important nutrients like protein, vitamins, carbohydrates, fats, and therapeutic potential. Flowers, with their favourable sensory and nutritional properties and the existence of bioactive components advantageous to human health, form a key sector for developing the food industry. It is essential to encourage the local use of flowers in order to maintain traditional norms, and many studies have been conducted to better understand the social and cultural contexts in which edible flowers are consumed. With the global market for natural and healthy diets, the nutritional characteristics, therapeutic advantages, active chemicals, and cooking techniques of edible species have been explored. Current techniques for extracting natural bioactive chemicals from flowers are helping to discover their constituents and produce food industry-beneficial additives. Correct taxonomy, toxicology, and a comprehensive practice guide for commercially grown flowers, processing, and preservation are still needed to promote edible flower usage. The scientific and technical information about edible flowers' nutritional profile, therapeutic effects, and phytochemical composition is evaluated and addressed to improve knowledge, dietary practices, and dietary investigation.

MPPs	Mitochondrial processing peptidase
ORAC	Oxygen radical absorbance capacity
Pl3K	Phosphatidylinositol-3 kinase
T47D	Human breast cancer cell line

1 Introduction

One of the most important ecosystems in Chhattisgarh may be situated on the Indian subcontinent, which is home to a vast array of unique plant and animal species [1]. These areas in Chhattisgarh, also known as the central region of India, conserve a wide variety of plant life and provide a wealth of wood and non-timber materials, such as gums, with significant economic values [2–4]. The first step in protecting these unique natural biological components is to measure and record plant variation. We can always count on healthy ecosystems, which are beneficial to humans in a variety of ways, to be characterized by high biodiversity [5]. Food webs, food chains, bioremediation, nutrient availability, and human subsistence all rely on biodiversity to function in harmony [6]. There are approximately 6922 km^2 of forest, including deep forest and open forest, as well as mangroves. It covers around 21.5% of the nations at the geographical region level. It has several applications, including community forestry, agroforestry management, replanting, and the restoration of damaged or demolished commercial and industrial sites [7, 8]. The term "agroforestry"simply refers to a combination between agriculture and forestry that has been employed for centuries [9–11]. Agroforestry practices are also becoming a realistic means of decreasing the adverse environmental impacts of the current state of affairs [12]. Chhattisgarh has several useful and nutritional plants since its forests comprise 42% of the state's total territory and are composed of tropical moist and tropical dry deciduous trees. From a conservationist's perspective, it is crucial to keep all of these temperate forests alive and well, as they are native to a wide variety of plant varieties and serve as a safe haven for many different kinds of wildlife [6]. Hence, securing these biotic assets is critical to maintaining a healthy ecosystem. The nutritional value of food and its accessibility have long shaped the eating habits of forest-dwelling communities, and people in these areas typically harvest their own food. Roots, rhizomes, tubers, fruits, seeds, flowers, and leaves are all consumed by those who live in the forest as a means of subsistence. As a result, these edible plants are crucial to the long-term viability and food security of people who make their homes in the nation's forests [13].

The state of Chhattisgarh is located at 80°15′ to 84°24′ E longitude and 17°46′ to 24° N latitude. The state consists of both hilly and flat areas throughout its entirety.

On average, 60 in. of precipitation fall each year. Rice is the primary crop produced in the state. Because of the state's exceptionally diverse plant and animal life, Chhattisgarh is often referred to as the "herbal state." Around 42% of the land area of the state is covered by woods. People who live in tribal communities are wholly reliant on the forest for their food and a variety of other needs [14]. Although farming is the chief source of income for indigenous communities, the forest and its resources are equally vital to the survival of indigenous and folk communities by providing for a wide range of needs, including food, medicine, fibres, and shelter. They rely heavily on farming to meet their food needs, but they also forage for wild roots, tubers, leaves, flowers, and fruits. In terms of ethnobotany, the state is not well known; the only important studies that have been written down can be found there. In this chapter, only edible flowers and their healing properties, as well as a few other ethnobotanical traits, are discussed. On the other hand, there is a lack of details concerning edible plants. This chapter discusses the wild plant species that they harvest for their edible qualities and then devour. Flowers have been eaten for a long time, but recently there has been a resurgence of interest in doing so, both for their visual beauty and any potential health benefits they may provide. New interest in edible flowers has led to a lot of research on their nutritional value, medicinal value, and phytochemical components [15]. There are many different phytonutrients in flowers, and some of them may help protect against chronic diseases. This chapter discusses the nutritional and pharmacological activities of edible flowers from Chhattisgarh, India. Whether edible flowers are to be considered functional foods or a component of our diets, however, more findings referring to their security and application are required [16, 17].

2 Edible Flowers of Chhattisgarh

Flowers are natural substances that are not only beautiful but also known for their nutritional profile and therapeutic perspective [18, 19]. People have been able to benefit in many ways from natural resources like wild edible plants. These benefits reflect long-standing interactions that have existed between plants and humans throughout different periods of history. Because of this, there is no question that people eat edible flowers that grow in the wild because the term farming has never been clearly defined. The edible flowers of Chhattisgarh originate from an extensive range of plant groups, genera, and species; however, the specific number of flowering plants that can be consumed varies from region to region. There is a wide variety of plants, but only a few are selected as edible, making accurate recognition of edible flowers crucial. A variety of edible flowers can be purchased commercially, and their popularity is growing rapidly. These blooms are most popular when consumed in moderation, but they also have many other uses in the kitchen, including in baked products, drinks, marmalade, salads, smoothies, and even as a replacement for vegetables in savoury dishes. There are so many edible flowers that it would be impossible to study them all [20, 21].

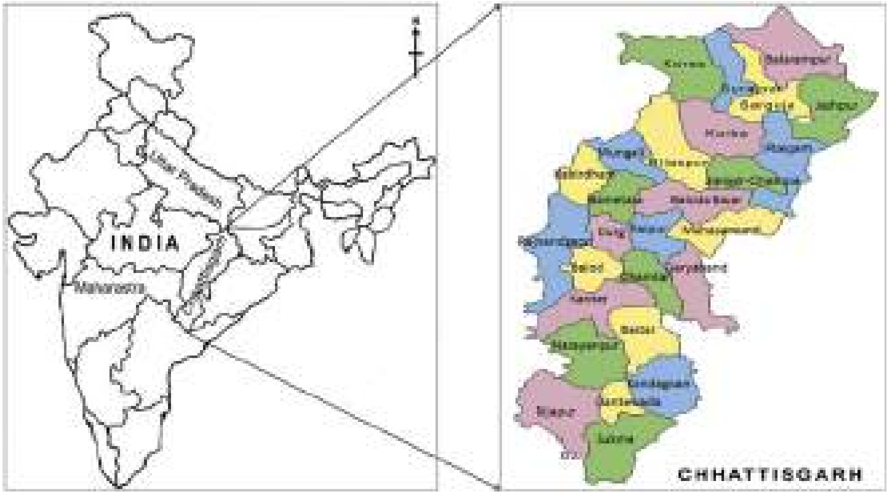

Fig. 1 Distribution of edible flowers in Chhattisgarh

3 Distribution of Edible Flowers in Chhattisgarh

An edible flower is defined as a safe, harmless, and non-toxic flower with health advantages that is taken as a component of human food. Since ancient times, they have consistently been a significant factor in supplying living organisms with various nutrients. It has been demonstrated that consuming flowers is a cultural tradition in a huge number of locations, including Raipur, Bilaspur, Raigarh, Janjgir-Champa, Baloda-Bazar, Bastar, Sarguja, Koriya, Gariyaband, Sakti, Sarangarh-Bilaigarh, Korba, Durg, and other locations of Chhattisgarh, India (Fig. 1). Edible flowers have become extremely popular around the world recently due to their attractive beauty and the therapeutic advantage associated with their specific aroma, flavour, and colouring [15]. Edible flowers have recently been at the centre of numerous investigations in the fields of food science, technology, and even pharmaceuticals. The goal of this chapter was to enhance the attractiveness of edible flowers as prospective food products by discussing their phytochemical components, health benefits, and toxicity. There is evidence that humans have been eating flowers for at least 2000 years. Several regions, including India, Pakistan, Sri Lanka, Vietnam, the USA, Australia, Kenya, and South Africa, have reported the consumption of edible flowers. Nowadays, you may eat flowers in salads, in light curries, or even by themselves as a vegetable. Certain edible flowers are suitable for stuffing or using in stir-fries [16, 22].

4 Traditional Use of Edible Flowers

The flowers are more than just decorative additions to the savoury dishes and sweet confections; rather, they offer a novel variety of tastes and boost the nutritional content of the dishes. They can be used as fresh salads, savoury dishes, soups, beverages, candies, jellies, spices, and colours. For example, *Tagetets erecta, Azadirachta indica, Rosa gallica, Cardia dichotomo, Brasica oleracea,* and *Tamarindus indicus* flowers are employed in a variety of culinary applications in dried form, powdered form, crystallized form, and foam form [23, 24].

There are many plants that have conventionally been used as edible flowers, such as *Madhuca latifolia* Roxb.*, Bombax malabaricum, Butea monosperma, Holarrhena antidysenterica, Indigofera casioides, Tamarindus indicus, Holostemma rheedianum Spreng, Crotalaria juncea L., Crotalaria incana Rottl., Celastrus paniculata Willd, C. renigera (Wall) Gagnep., C. fistula L., C. arborea* Roxb.*, Bauhinia racemosa Lam., Alangium salvifolium, Brassica oleracea var. botr. Linn, Couroupita guianensis Aubl, Brassica oleracea, Cordia dichotoma, Cucurbita L., Moringa oleifera, Hibiscus sabdariffa L., Azadirachta indica, Solanum xanthocarpum, Solanum xanthocarpum, Hibiscus rosa-sinensis, Helianthus annuus L., Rosa gallica, and Tagetet erecta.* The comprehensive information, however, was not provided.

The following key point describes the traditional uses of edible flowers:

- Provides a major portion of the calories and nutrients needed on a yearly basis [25].
- It is possible to use it as a main dietary replacement, especially during times of seasonal food crisis.
- For use as a salad topping, appetizer, main dish, beverage, or sweet course.
- Edible flowers have been used in a wide variety of recipes for tea, baked goods, sauces, jellies, syrups, flavoured liquors, vinegars, honey, and oils.
- Certain edible flowers that are safe to eat can be incorporated into stir-fried dishes.
- Offering an option for the application of natural dyes and colourants in the food industry.
- Salads, appetizers, soups, main dishes, confectionery, and beverages all benefit from their colourful, aromatic flavours, and refreshing aromas [26].
- Even though edible flowers are popular in their current forms, they can also be baked, frozen (as ice cubes), bottled in sweets, or stored with volatiles [15].
- Edible flower petals can be steeped in oil or vinegar to provide a floral fragrance.
- Sugar and egg whites can be employed to crystallize flowers for candy [27].
- Flowers’ essential oils are applicable in aromatherapy treatments.
- Edible flowers are included in therapeutic diets.
- Edible flowers were employed as garnishes on dishes served to the nobles, particularly during formal events like feasts and festivals [15, 28]. The uses of many edible flowers in Chhattisgarh are listed in Table 1.

5 Edible Flowers as Cultural and Regional Foods

A state that is located in the centre of India is called Chhattisgarh, because the term “Chhattisgarh“is made up of two words: first “Chhattis” and second “Garh,” which means 36 forts. The name Chhattisgarh is meant to represent the large group of forts

Table 1 Uses and family description of edible flower of Chhattisgarh, India

S. N.	Plant Local Name	Scientific Name	Edible parts	Family	Uses	References
1	Mahua	*Madhuca latifolia* Roxb.	Flower	Sapotaceae	The fresh as well as dry flowers are eaten along with seed	[29]
2	Semal	*Bombax malabaricum*	Flower	Bombacaceae	The young flower buds, mixed with Mahua flowers, are eaten during food scarcity	[29]
3	Palash	*Butea monosperma*	Flower	Fabaceae	The young flower buds are used as vegetable along with pickled oil	[29]
4	Koraya	*Holarrhena antidysenterica*	Flower	Apocynaceae	The flower bud is cooked as vegetable. Boiled flowers are cooked and eaten as vegetable	[29, 30]
5	Girhul	*Indigofera casioides*	Flower	Fabaceae	Flower bud is cooked as vegetable and curry	[29]
6	Imali	*Tamarindus indicus*	Flower	Fabaceae	Flowers are eaten as vegetable	[29]

that are located in the area. Almost 70% of the community is employed in agriculture, giving rise to the region's other name, the "Rice Bowl" of Central India. Rice is the major crop in the province, and it also makes up the majority of the food of the people who live here. It is abundantly clear that as the rate of urbanization rises, people's conventional dietary patterns are shifting in the direction of a culture around unhealthy food. Nevertheless, nearly 80% of the population of Chhattisgarh lives in rural areas. As a consequence of this, the state's traditional culture is still being practised, and the majority of the people's eating habits have not altered [34]. Foods from Chhattisgarh are both tasty and nutritious. Because of the state's extensive forest area, the rural and tribal people who live there supplement their diets with forest-grown roots, tubers, leaves, flowers, and fruits. They add a distinct flavour and beneficial properties of nature to traditional Chhattisgarh dishes. There are various types of leaves, tubers, roots, and flowers eaten locally here [35, 36]. This chapter delves into the typical flower-based food of Chhattisgarh and gives information on the flowers, leaves, tubers, rhizomes, and roots used in these dishes. Vegetarianism is highly prevalent in Chhattisgarh, and the state's cuisine makes excellent use of locally grown vegetables and other nutritious ingredients. Every nation's traditional cuisine has survived and is the healthiest option for its citizens. There is a worldwide trend towards continually low fruit and vegetable consumption [37]. Flowers, rhizomes, fruits, leaves, and other plant-based foods make up a significant food group that is rich in necessary minerals and vitamins; ensuring adequate consumption of this group is especially crucial in Chhattisgarh, which suffers from chronic nutritional deficits [38]. The food cultures of Chhattisgarh are the path forward towards adopting sustainable practiscs and making use of the native materials at our disposal to enhance our regular intake. Not only does the processing and preparation of ethnic foods recognize the inventiveness of the local inhabitants and their wealth of cultural and historical heritage, but it also validates their tremendous competence in supporting the existence of the environment in its entirety [39].

Dietary practices are a significant factor in determining the state of people's healthcare. The growth of the human population has been paralleled by the steady evolution of the culture surrounding local foods. It is determined by geographical position, environmental conditions, seasonal fluctuations, soil composition, water supply, forest area, agricultural practices, immigration, and the impact of conquerors, as well as the labour routines of the inhabitants in the area. The culture around traditional foods is based on an experiential context that develops over the course of generations. Food's function in human existence is not confined to simply satisfying appetite; rather, it has a far larger meaning and is an essential component in practically every facet of human existence, including the family, social relationships, festivals, and spiritual rites. The residents of a region have access to the healthiest, most nutritious food options available thanks to the traditional cuisine that has been passed down through the generations [40, 41]. Accepting unhealthy, out-of-region eating habits in the name of globalization is not only unethical but also potentially damaging to people's health. In 2015, the Global Burden of Disease study found that bad food was the largest cause of immorality worldwide, largely due to the shift from a conventional to a modern eating pattern. Each nation's traditional cuisine has stood the test of time and is the healthiest option for its citizens. While rice and vegetables are the most common foods in Chhattisgarh, pulses, green leafy vegetables (GLV), tubers, flowers, and roots are also part of a typical Chhattisgarh lunch. The rural and tribal residents of the state have acquired the ability to do with what nature provides because of the extensive forest cover in their area. The ethnic food of Chhattisgarh is thought to have beneficial health effects, which are supported by both traditional medical practices and more contemporary scientific studies. The food culture of Chhattisgarh is both abundant and extremely varied. The state's numerous dietary patterns are intricately connected to aspects of social authenticity, religious practice, and other sociocultural factors, in addition to local farming techniques and a broad variety of readily available food. Well over 50% of the state's inhabitants can acquire their meals and vegetables from the crops they grow, and edible flowers are a significant component of those crops. It is farmed or cultivated in almost every region, and about half of Chhattisgarh's population uses it as their primary source of nutrition [42].

6 Nutritional Profiles of Edible Flowers

Although the nutritional value of many forest meals is unclear, there seems to be sufficient evidence to suggest that forest foods are beneficial to one's health in terms of their nutritional content. It is of the utmost priority to support experiments on the nutritional values of foods found in forests, since this will inspire people to consume a larger amount of food and offer them a more optimal nutritional profile [14, 43]. Edible flowers have been a component of the human diet for thousands of years. Their therapeutic characteristics and subsequent health benefits have led to their classification as a type of plant cuisine. *Brassica oleracea var botr. Linn, Brassica oleracea, Cordia dichotoma, Cordia dichotoma, Moringa oleifera, Hibiscus sabdariffa L., Solanum xanthocarpum, Helianthus annuus L., Rosa gallica, Tagetes*, *Madhuca latifolia Roxb., Crotalaria juncea L., Bombax malabaricum, Butea monosperma, Tamarindus indicus, C. fistula L., and Bauhinia racemosa Lam.* are the many types of edible flowers that have been eaten since ancient periods. Flowers that are harmful or otherwise unsafe for humans or have poor nutritional benefits are not typically included in human food [44, 45]. Certain flower varieties include poisonous compounds that may reduce their nutritional value, such as alkaloids, oxalate, cyanogenic glycosides, nitrate, or phytate, or cause serious harm to users [15, 44, 46]. These edible flowers are sold commercially or used in human food. It is important to confirm the nutritional profile and other properties associated with human nourishment for the foods that are generally accepted as edible. Edible flowers vary widely in terms of total carbs, soluble fibre, and micronutrients, depending on the type of edible flower [15, 26, 44, 46, 47]. The majority of edible flowers are composed entirely of water molecules (more than 72%) and contain the least concentration of protein and vitamins. Edible flowers also include varying quantities of carbohydrates, crude fibre, fat, lipids, and minerals. Edible flowers include a variety of bioactive components, like pigments, carotenoids, phenolic compounds, terpenoids, flavonoids, and volatile oils, which offer a broad range of beneficial qualities. The proximate composition and mineral content concentration of many edible flowers from Chhattisgarh, India, are displayed in Tables 2 and 3, respectively.

7 Bioactive Components of Edible Flowers

Bioactive components are clinically evident, naturally produced organic molecules that do not constitute nutrients but have therapeutic properties that promote public health. They enhance the plant's appearance, aroma, and taste in addition to protecting it from illness and environmental damage [72]. Most of the bioactive chemicals in edible flowers are polyphenol compounds, carotenes, flavonoids, and anthocyanins [15, 71]. Carotenoids and flavonoids give flowers their colour and antioxidant capacity [73]. Lutein and flavonoids have been examined for their potential to treat cytotoxic cancers [73–76]. Several types of polyphenol components, including phenolic acids, flavonoids, flavonols, and anthocyanins, are found in edible flowers, which have strong antioxidant potential, act as a shield against free radicals, and have been linked to improved human metabolism [77–80]. Polyphenols are known to have antioxidant properties in in vitro and in vivo examinations [81]. Many therapeutic properties may be contributed by phenolic components, carotenes (colourants) [82], isothiocyanates, volatile oils (the primary source of the flowers' aroma) [83, 84], and cyclotides, which are circular plant peptides. The ingestion of edible flowers has substantially expanded recently due to their multiple health advantages, which are contributed in part by the abundance of phytonutrients found in edible flowers. Although many investigations have been conducted, there has not been a comprehensive literature review prepared on the nutritional profile of edible flowers and the phytonutrients found in them. Prior to recently, exploration of edible flowers focused on their nutrition, aroma, and volatile oils [85, 86]. However, phytonutrients, the primary beneficial constituents of edible flowers, have received increased attention in investigations. Phytochemicals are the active molecules found in vegetables and plant foods that significantly lower the chances of serious illnesses like tumours, fever, cancer, CVD, inflammation, and cytotoxicity [87, 88]. Figure 2 displays the various bioactive components of edible flowers from Chhattisgarh.

7.1 Anthocyanins

Anthocyanins are water-soluble phytochemicals that belong to the flavonoid group. These are the natural colour pigments that are responsible for the colouring of flowers. The pH value, metal ions, and co-pigments all play a role in determining their unique coloration. Anthocyanins have been demonstrated to have a higher potential for eliminating free radicals [89]. These molecules also play a significant role in the prevention of several illnesses, including malignancy, cardiac disease, overweight, hypertension, and diabetes. Anthocyanin can be found in high

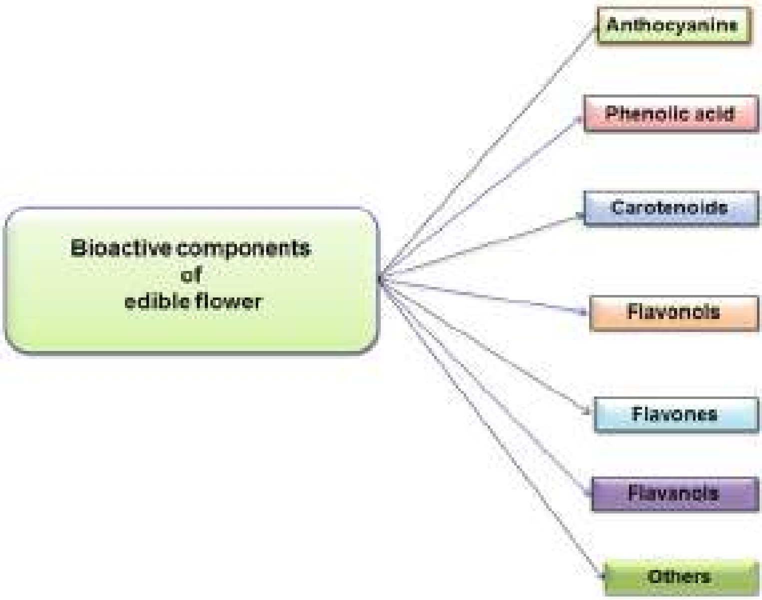

Fig. 2 Bioactive components of edible flowers

concentrations in *Rosa gallica, Solanum xanthocarpum, Hibiscus rosasinensis, Hibiscus sabdariffa L., Moringa oleifera, Cordia dichotoma, Cordia dichotoma, and Tagetets*, among other edible flowers of the plants. Kumari et al. (2017) [90] examined the anthocyanin of various Indian cultivars of *Rosa gallica*. Employing HPLC-PDA, she identified cyanidin 3,5-di-O-glucoside and pelargonidin 3,5-di-O-glucoside. The cyanidin 3,5-di-O-glucoside has been the chief anthocyanin responsible for the reddish and pinkish colour of the edible flower. Pelargonidin 3,5-di-O-glucoside has also been found as an anthocyanin in the carrot-red type of colour of the edible flower [91].

7.2 Carotenoids

Carotenoids are natural pigments found in plants. They give flowers their colours, which range from yellow to orange to red. Carotenoids contain many isoprenoid molecules [92]. The proportion of carotenoids in blossoms varies substantially across floral taxa. Carotenoids are a vital part of both human and animal nutrition and are absorbed from healthy meals and supplementation. According to the findings of numerous studies, carotenoids might decrease the development of vitamin A deficiency, age-related macular degeneration (AMD), blindness, UV exposure, malignancy, cytotoxicity, and CVD. Several studies have shown that Tagetes flowers could be a good source of carotenoids because they contain lutin and its derivatives. At a low amount, zeaxanthin, antheraxanthin, β-cryptoxanthin, β-carotene, α-carotene, zeinoxanthin, and violaxanthin have also been detected in many edible flowers like *Indigofera casioides*, *Crotalaria juncea L., Bauhinia racemosa L., Brassica oleracea,* etc. *Madhuca latifolia, Tamarindus indicus, Moringa oliefera, Rosa gallica, and Cardia dichotoma* flowers have been found to contain many carotenoids like lutein, flavoxanthin, β-carotene, α-carotene, lycopene, rubixanthin, zeaxanthin, α-cryptoxanthin, 13-*cis*-carotene, α-carotene, *trans*-carotene, 9-*cis*-carotene, luteoxanthin, violaxanthin, zeaxanthin, neoxanthin, and lutein epoxide [89, 92–95].

7.3 Flavonols

The group of flavonoids is referred to as flavonols. It is one of the most successful sources of flavonoids. The flavonols contain many sub-groups, such as quercetin, kaempferol, isorhamnetin, and myricetin, along with their derivatives. Flavonols were widely found in edible flowers. They were found in *Rosa gallica* [96], *Moringa oliefera, C. fistula L., Cardia dichotoma, Solonum xanthocarpum, Hibiscus rosa sinensis*, and cactus in a variety of morphologies [97]. *Tegetete*, *Rosa gallica, and Couroupita guianensis Aubl*. also noted the variety of primary flavonols that are present in phenolic flavonoids. Researchers have found that the most common flavonol aglycones in *Rosa gallica* petals are kaempferol and quercetin [91, 92, 98–100]. The majority of edible flowers contain large concentrations of flavonols in comparison to other flavonoids. Shrivastav et al. (2016) [29] reported that the edible flowers of *Butea monosperma, Bombox mealricum,* and *Madhuka latifolia* Roxb. could have isorhamnetin, quercetin, and their glycosides. Ekka and Ekka (2016) [30] also found that *Crotalaria juncea* flowers had several types of flavonols, like kaempferol, quercetin, isorhamnetin, and their glycosides. The above findings provided more evidence that flavonols could be found in many common edible flowers.

7.4 Flavones

Flavones are a subclass of flavonoid whose skeleton is 2-phenylchromen-4-one (2-phenyl-1-benzopyran-4-one). Flavones are a derivative of the Latin word "flavus," which describes a yellowish colour pigment. Flavones are widely available in edible flowers of many kinds. Acacetin, chrysoeriol, apigenin, luteolin, and their corresponding glucosides are the main flavones. There is a rich supply of flavones in a variety of edible flowers. There was a high concentration of flavones in all types of edible flowers that originated from the Asteraceae family, such as *Helianthus annuus* and *Tegetes* [16]. There is a rich supply of flavones in a variety of edible flowers. *Tamaricus indicus* flowers were discovered to contain a significant amount of luteolin-7-glucoside [29]. *Chrysanthemum* and *Tegetet* flowers contain greater amounts of flavones, including acacetin, acacetin-7-O-glucoside, apigenin,

apigenin-7-O-glucoside, luteolin, and luteolin-7-O-glucoside. These flavones have been claimed to have anti-inflammatory action. *Rosa gallica* and *Moringa olifera* both contain luteolin in their respective preparations. Apigenin glycosides were the predominant flavones identified in *Tegetet* [101].

7.5 Flavanols

Flavanols have been found in edible flowers that are made up of catechin, epicatechin, epicatechin gallate, and epigallocatechin gallate. Many researchers reported that *Rosa gallica* had a greater concentration of flavanols in edible flowers [16, 96]. Catechin, epicatechin, epicatechin gallate, and epigallocatechin gallate are the chief constituents of *Rosa gallica*. Many flavanols have been reported in *Brassica oleracea, Madhuca latifolia*, *Butea monosperma, and Bombox malabaricum* flowers [96, 98, 102, 103]. Many researchers reported flavanols (catechins) in *Chrysanthemum* flowers in the highest concentration. The majority of the crude extract of *Rosa gallica* flowers is composed of flavanols, specifically catechin and epigallocatechin gallate [104].

7.6 Phenolic Acids

To simplify, "phenolic acids" refer to all phenolic compounds with a single carboxylic acid group. Phenol-carboxylic acid, mostly called polyphenols, is an abundant phenolic acid found in many plants and edible flowers. They can be found in many different types of edible flowers. Another important class of secondary metabolites found in edible flowers are phenolic acids. There have been many reports of the presence of phenolic acids in *Rosa gallica* [105], *Cardia dichotoma, Alangium solvifolum, Chrysanthemum*, and *Brassica oleracea* [106]. Other phenolic acids comprise protocatechuic acid, caffeic acid, and gallic acid. An important category of phytochemicals that are identified in edible flowers is called phenolic acids. *Solanum xanthocarpum* flowers contain many phenolic compounds like coumaric acid, quercetin, rutin, ferulic acid, hydroxybenzoic acid, caffeic acid, and cinnamic acid in higher concentrations. *Indigofera cosioides* blossoms contain significant amounts of polyphenolic compounds [107].

7.7 Others

Various types of phytochemicals like carotenoid (β-carotene), phytosterols (β-sitosterol) [108], alkaloids, lignans [109–111], neolignans [112], coumarins, and bisabolo are also found in various edible flowers. The quantities of these phytonutrients were significantly low, and their functional properties were not as potent [113, 114].

8 Therapeutic Potential of Edible Flowers

The purpose of this chapter has been to examine the conventional uses, phytonutrients, therapeutic properties, and nutritional profiles of various edible flowers in Chhattisgarh, India. Flavonols, flavones, flavonoids, anthocyanins, phenolic acids, and their derivatives were discovered to be ubiquitous phytonutrients in a variety of locally eaten flowering plant species, all of which were linked to the edible flowers' reported therapeutic properties. Edible flowers have various health advantages, including antioxidant, anti-inflammatory, anticancer, anti-diabetic, anti-obesity, neuroprotective, anti-carcinogenic, anti-microbial, hepatoprotective, analgesic, and antiulcer characteristics [115–117]. These effects are due to flower phytonutrients and secondary metabolites. Advantages to health from edible flowers are also discussed [118]. The therapeutic potential in edible flowers of Chhattisgarh, India, are displayed in Fig. 3.

8.1 Anti-oxidant Activity

Oxidative stress, ageing, neurological illnesses, cerebrovascular disease, metabolic disorders, cardiovascular disease, tumours, and cytotoxemia are all caused by an excess production of free oxidative radicals. The edible flowers possess strong antioxidant properties. The antioxidant activities were investigated using both *in-vitro* (DPPH, ABTS, and ORAC) and *in-vivo* (lipid peroxidation assay)

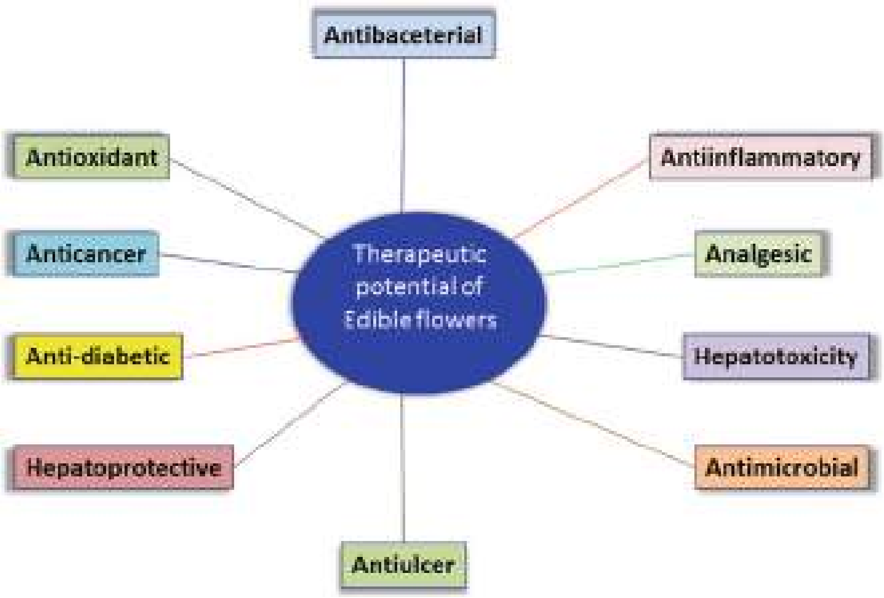

Fig. 3 Therapeutic potentials of edible flower

techniques [119]. Many researchers reported that edible flowers displayed higher antioxidant potential [120, 121]. Some edible flower extracts, like *Madhuca latifolia* Roxb., *Butea monosperma*, *Tamarindus indicus*, and *Holarrhena antidysenterica* have shown greater capacity to scavenge free radicals [122, 123]. Edible flowers have been shown to have considerable anti-oxidant potential owing to the presence of anthocyanins, flavonoids, phenolic acids, alkaloids, terpenoids, and glycosides. Edible flowers have a stronger antioxidant potential than other plant parts like leaves, roots, rhizomes, and barks, which may be due to the higher number of phenolic compounds, particularly flavonoids [124]. The phytochemical flavonoids, alkaloids, terpenoids, steroids, carbohydrates, and glycosides in edible flowers might help them fight free radicals. The biological processes that occur within the human organism generate free radicals as an unwanted consequence. Due to reactive compounds, they cause the oxidative destruction of lipids, proteins, and ultimately DNA. A well-balanced anti-oxidative inhibition system can help counteract damage. Edible flowers are known to be rich providers of a number of different natural bioactive substances, such as vitamins. Healthy food sources, including polyphenols, are of major importance because they provide better antioxidant sources. Phenolic compounds have been shown to have a good impact on chronic health issues such as CVD, diabetes, hypertension, heart disease, hepatoprotective, and neurological illnesses [125–127].

8.2 Anti-inflammatory

The inflammatory response is a necessary and helpful part of the body's physiology. Its main function is to protect the host from both poisons made by the body and microorganisms that come from outside the body. Inflammatory conditions can start off as a short-term acute condition, but they can also turn into a long-term chronic condition, which can cause irreparable harm to the host's health. The anti-inflammatory properties of *Madhuca latifolia* Roxb., *Bombax malabaricum, Butea monosperma, Holarrhena antidysenterica, Indigofera casioides, Tamarindus indicus, Crotalaria juncea L., C. fistula L., C. arborea* Roxb., *Couroupita guianensis Aubl, Cordia dichotoma, Moringa oleifera, Hibiscus sabdariffa L., and Solanum xanthocarpum* demonstrated strong inflammation action. Evaluation of the inflammation effect of edible flower extracts on chronic inflammatory diseases was conducted using cell line assays such as lipopolysaccharide (LPS)-induced RAW 264.7 macrophage activation and in vivo assays such as dimethylbenzene (DMB)-induced ear vasodilatation, acetic acid-induced fluid accumulation, and carrageenan-induced paw oedema. The results indicated that edible flower extracts reduced the severity of acute inflammation. Inflammation is a natural process that causes the immune system to work harder [128]. It is an essential part of the body's physiologic function and acts as a protective mechanism against bacterial infections, viruses, and poisons. The cell simulation method was used to investigate the characteristics of inflammation in the extract of a variety of edible flowers. Many edible flowers possess strong inflammation potential [89, 129].

8.3 Anti-cancer

Investigations in epidemiology have demonstrated that a diet rich in edible flowers, fruits, rhizomes, and vegetables is closely connected with a lower risk of developing long-term diseases [130]. Some edible flowers involve *Chrotalarea juncea* L., *Chrotalarea incana* Rottl., *Rosa gallica*, *Hibiscus sabdariffa*, and *Casea fistula* L. [131–133]. Edible flowers exhibit powerful actions against cancers of the liver, bladder, prostate, breast, and colon. The ability of edible flowers to prevent cancer is mostly attributable to phytonutrients like gallic acid, protocatechuic acids, flavonoids, and rugethanoids B [133, 134]. These edible flowers had the ability to provide cancer-fighting medications. Edible flowers have shown significant activity against a variety of different cancers. The growth and development of malignant breast tumours can be inhibited by consuming modest doses of lutein from marigold extract in their diet. In recent studies, the MTT test was used to show that the extracts of *Bauhinia tomentosa* flowers and *Tagetes erecta* petals were effective against the liver cancer cell lines HePG2 and MCF-7. Skin disorders such as skin damage and skin cancer have emerged as a topic of attention for people all over the world in recent years. The anticancer properties of *Hibiscus sabdariffa*, which is an abundant source of flavonoids, have been the subject of extensive research [135–137]. Researchers tested its cytotoxicity on T47D breast cancer cells and obtained positive results [138]. In a manner comparable to that which was addressed previously, a few studies demonstrated the anticancer action of edible rose blooms. The findings suggested, taken together, that edible flowers might be an even more effective source of anticancer drugs [139].

8.4 Anti-obesity

The build-up of excess fat in the body, the process of fatty acid synthesis, and an imbalance in energy levels all contribute to obesity, also known as overweight, which is associated with adipocyte differentiation and a higher risk of health-related issues. Substances with natural bioactive properties can be utilized to prevent obesity. Obesity or being overweight happens when a person takes in more calories than they use up, and it always leads to a number of metabolic and long-term conditions, such as trouble sleeping, high blood pressure, hypertension, high cholesterol, and diabetes [140]. Several edible flowers, including *Madhuca latifolia* Roxb.*, Bombax malabaricum, Butea monosperma, Holarrhena antidysenterica, Indigofera casioides, Tamarindus indicus, Crotalaria juncea L., C. fistula L., C. arborea* Roxb.*, Couroupita guianensis Aubl, Cordia dichotoma, Moringa oleifera, Hibiscus sabdariffa L., and Solanum xanthocarpum*, demonstrated an inhibiting effect on obesity [141, 142]. Various phytochemicals acted as mediators between the enzyme and biochemical pathways in lipid burning. *Rosa gallica* extract either controlled calorie consumption and expenditure by decreasing α-amylase activities and preventing carbohydrate or starch uptake or prevented adipocyte development by influencing the PI3K and MAP-kinase pathways.

8.5 Neuroprotective Activity

Alzheimer's disease and Parkinson's disease are both common forms of dementia that cause memory loss. Neurodegeneration is closely related to age, and both of these disorders are connected with ageing. Many researchers discovered, through the use of a cerebral I/R model, it has the potential to significantly enhance the neurological deficiency levels as well as the infract volume [143]. In the *Caenorhabditis elegans* model, flower extracts of *Tagetes erecta* showed potential antioxidant and neuroprotective characteristics. Polyphenols, mainly laricitin and its glycosides, were responsible for these activities and were shown to be responsible for them [144]. Degradation of dopaminergic neurons is also the root cause of ischemia, which is one of the main causes of death and chronic disability. The potent neuroprotective effect of edible flowers, such as *Chrysanthemum, Rosa gallica*, and *Honeysuckle*, was assessed in an in vivo model using glutamate, arachidonic acid, and 6-hydroxydopamine (6-OHDA)-induced serious injuries, posterior cerebral artery occlusion-induced focal cerebral ischemia, and the neurotoxin 1-methyl-4-phenylpyridinium. MPP+'s ability to cause apoptosis in human neuroblastoma cells could be stopped by the phenolic acid found in edible flowers [89].

8.6 Anti-diabetic

Metabolic disorder diabetes mellitus is associated with reduced or insufficient insulin secretion or function. Diabetes can also be referred to as "adult-onset diabetes." As a consequence, the body is unable to metabolize glucose, which ultimately leads to increased quantities of glucose in the blood. Many edible flowers have the capacity to reduce high levels of glucose in the blood, which was evaluated in comparison to insulin [145]. It was found that *Catharanthus roseus* flower ethanol extracts were better at lowering blood sugar levels than the main diagnostic medicine. Due to the liver using more glucose, hypoglycaemia has been seen [146]. Because *Butea monosperma* flowers cause a significant increase in the amount of glucose that is taken up by *Saccharomyces cerevisiae*, there is greater potential for their use in the treatment of diabetes [147]. Various phytochemicals, particularly flavonoids and terpenoids, have a stimulating impact on the body's ability to take in glucose. The anti-diabetic benefits of these flowers are caused by the suppression of enzymes involved in the metabolism of carbohydrates, the control of glucose transporters, the renewal of beta cells, and the enhancement of insulin-generating function [148].

8.7 Hepatoprotective Activity

Edible flowers and their natural active components have received an abundance of interest due to their remarkable ability to treat hepatic issues. The aqueous extract of *Madhuca latifolia* was examined, and the result indicated that it has a strong hepatoprotective reaction against carbon tetrachloride. This was a direct consequence of the serum levels of transaminases, bilirubin, alkaline phosphatase, and triglycerides regenerating themselves. Both the water and methanolic extracts of the edible flowers of *Butea monosperma* demonstrated significant hepatoprotective effects. Another aqueous extract of *Bombax ceiba* flowers showed that these flowers have hepatoprotective activity against CCl_4-induced hepatic injury [29, 149]. Abdelhafez et al. (2018) [150] investigated the possible hepatoprotective activity of *Hibiscus malvaviscus* against the hepatic injury caused by CCl_4 in mice, and findings indicated that dichloromethane and ethyl acetate fractions considerably reduced the seriousness of hepatic damage in rodents.

8.8 Antimicrobial Activity

A plant extract of *Azadirichta indica* is used in the production of natural high-antimicrobial agents. The flowers of *Brassica oleracea* and *Cardia dichotoma* plants were effective against both gram-negative and gram-positive bacteria [14]. Also, antibacterial activity has been found in both ethanolic and aqueous extracts of *Hibiscus rosa-sinensis* against a number of foodborne bacterial infections [151]. *Rosa gallica* methanolic extracts have an antimicrobial effect that is effective against a variety of bacterial and yeast strains [89].

8.9 Others

Numerous plant families and groups across Chhattisgarh, India, rely on edible flowers as a primary means of ensuring their continued access to food and means of survival. It is believed that around 800 different plant species are used as food in India, the majority of which are eaten by the indigenous people. Consuming edible flowers is vital for the eating habits of humans in several communities and is intricately tied to practically all areas of the sociocultural, spiritual, and social welfare of these humans and communities. There is a critical role for the consumption of edible flowers in satisfying the nutritional requirements of rural populations [147, 152]. There are many varieties of edible flowers, and these flowers have been used in a wide variety of ways across a variety of socioeconomic and geographic settings. In addition, there have been substantial reports that suggest that eating wild foods has been a common activity for a very long time [153]. Many of the therapeutic advantages associated with consuming edible flowers are due to the high concentrations of phytonutrients. Both *Rosa gallica* and *Hibiscus*, which are members of the Malvaceae family, have a number of medicinal properties. *Rosa gallica* was shown to be anti-cholesterol, anti-hypertensive, and anti-diabetic [16]. Both delphinidin-3-O-sambubioside and cyanidin-3-O-sambubioside were important, but the biological causes are still unknown. Hibiscus effects of on epileptic seizures and fertility suppression. Also, it helped with healthy hair, tissue repair, and immunology. Two chrysanthemum species were found to significantly reduce the formation of multiple AGEs in the bovine serum albumin (BSA)/glucose and BSA/fructose systems [154, 155]. This finding provides the possibility for the formulation of new diagnostic approaches for the prevention of diseases linked to glycosylation. In in vivo studies, the use of *Rosa gallica* extract resulted in a reduction in blood pressure in both acute and chronic situations. Anti-HIV-1 properties have been identified in rose species that could be consumed [16]. Despite substantial research into the possible health advantages of natural active components in edible flowers, surprisingly little is known about these plants.

9 Overview of Commercial Edible Flowers

Flowers have always played an important role in human culture as well as in the business and decorating worlds. Edible flowers are popular all over the world because they are pretty and healthy. Flowers can be used in many ways. They can be used to add scent, flavour, and colour, and they can also be used to decorate and make food and drinks. Before people can eat flowers, though, their biochemistry needs to be carefully studied. Roses, marigolds, hibiscus, calendula, and other flowers like these were often used in different kinds of food. The floriculture market gets a boost when flowers are grown specifically for their culinary qualities. Floriculture in India is considered an economy with tremendous growth potential. The importance of commercial floriculture with regard to international trade is growing. The liberalization of economic and trade policy created the foundation for the growth of flower production with an emphasis on exportation. Flowers are cultivated not just for their aesthetic value but also because of the nutritional and therapeutic benefits that they offer. Edible flowers have been utilized in a variety of ways throughout a wide range of international locales, including for their nutritional worth, medicinal function, flavour, form, and aesthetic appeal [15, 26]. Many flowers consumed are referred to as edible flowers. Until they are put to use, many parts of flowers, like sepals, petals, carpels, and filaments, are often plucked. Generally, edible flowers are taken in their entirety; however, depending on the kind of flower, certain sections of the flower should be ingested. In addition, it is necessary to remove some sections of certain flowers because of their bitterness. They are saved for use at a later time by employing preservation methods such as drying, freezing, or steeping in oil [156].

Regional and national preferences in food preparation and consumption are shifting. More and more consumers are learning the importance of eating well and choosing foods that meet their nutritional needs. Studies have shown that edible flowers are extremely beneficial to human health due to their abundance of beneficial chemicals, such as antioxidants, anti-carcinogens, vitamins, and many others [157]. Considering the interconnectedness of elements like effective input utilization, cost benefits, improved product quality, and ecological processes is also crucial to the enterprises' success. More people are aware of the serious decline in natural resources and the deterioration of the environment, and this has increased the pressure to make any creative activity as eco-friendly as possible [158]. Flowers have long been used as key components in a wide variety of dishes. Edible flowers are employed for both their aesthetic value and their sensory qualities [159]. The visual appeal of a meal can be affected by both the ingredients used and the presentation. Quality and aesthetics affect the appearance of meals. Edible flowers can boost a dish's attractiveness.

Edible flowers have not been grown by the floriculture industry in the past, but doing so could open up a new market and give the industry a new perspective. Certain flowers are deadly; therefore, it is important to know which ones to avoid [160]. Flowers that are often used in cooking include the *Chrysanthemum*, *Tegetets erecta*, *Madhuca latifolia* Roxb*., Bombax malabaricum, Butea monosperma, Holarrhena antidysenterica, Indigofera casioides, Tamarindus indicus, Crotalaria juncea L., C. fistula L., C. arborea* Roxb*., Couroupita guianensis Aubl., Cordia dichotoma, Moringa oleifera, Hibiscus sabdariffa L., and Solanum xanthocarpum*.

Edible flowers were a big part of traditional ways of life that are coming back thanks to globalization and better consumer knowledge. Now, more than ever, edible flowers are all the rage as a trendy new food trend in both well-known and new countries, making competition fierce in this previously untapped, unique area. Because of the COVID-19 situation right now, the flower business is looking into new options. While the number of people who grow and market edible flowers (in places like supermarkets, flea markets, and online) grows, the expectations of consumers and chefs alike continue to rise. They will be the cutting-edge components of next-generation food varieties [28]. When a flower is grown for its edible petals, it boosts the economy in a way that is hard to measure. In addition to their aesthetic value, flowers serve an essential function in agriculture: pollination. The primary factor driving the expansion of the global edible flower market is the increasing application of edible flowers as a supplement in the nutritional, food, and pharmaceutical industries. This has a beneficial effect on edible flower yield. The demand for them is rising all around the world since chefs and regular people alike see them as a healthy and secure meal option. You can also find them in a variety of dishes, drinks, decorations, baked goods, and salads. When compared to the costs of growing other crops, these ones are prohibitively expensive. The purchase of improved varieties for organic agriculture is a major cost driver. Edible flowers have a short shelf life, so they need to be eaten right away after being sold at the market. There are many geographic areas in the market for edible flowers, like Raipur, Bilaspur, Durg, Jagadalpur, and Raigarh city of Chhattisgarh, India. At the time of the evaluation, it was thought that the unique flavour and taste of edible flowers were the main reason for the growth of the regional market. Nevertheless, currently, there is no reliable evidence for the Indian edible flower market. This is due to the fact that the majority of edible flowers in India are harvested from the wild. As a result, there is a requirement to strengthen the market in economies that are experiencing economic growth [89, 161].

10 Conclusions

Edible flowers are becoming more popular in modern nutrition, mostly because of improvements in the nutritional value of a variety of foods and meals. Generally, this has a potentially therapeutic influence on public health. Edible flowers are a natural product that can be found all over the world. The vast majority of them have multiple phytochemicals that are good for your health, which is becoming more and more interesting. Numerous edible flowers have been used as a healthy diet for a long time. Recent research has shown that they are good for your health and found the active molecules and how they work to treat illness. Also, studies have been done to find out if common edible flowers are safe to eat, the best way to use them, and how much to use. Yet, due to the vast number of edible flowers that may be found across the globe, only a small portion of these flowers have been researched. We think that more research should be done to find the best ways to use edible flowers. This would make edible flowers more likely to be used as food ingredients and would also help to avoid any possible risks. Edible flowers have renewed interest in them, both because they look nice and because they may have health benefits. As their popularity has grown, more attention has been paid to their nutritional profiles, therapeutic potential, and natural bioactive components. Edible flowers have a wide range of phytonutrients. Some of these have been shown to reduce inflammation and act as antioxidants, which are two of the main reasons why we age and get sick over time. The composition and bioactivity of edible flowers have been studied. However, further data on the security and use of edible flowers is required before they can be termed functional foods or a part of our diet. Edible flowers are getting more attention in the present day as a result of their remarkable nutritional potential. Nutritionally and phytochemically, edible flowers are a great resource. The prominent phytochemicals found in edible flowers include phenolic compounds, carotenoids, terpenoids, flavonoids, and anthocyanins. Effective therapeutic potential such as anti-diabetic, anti-cancer, cytotoxicity, anti-inflammatory, antibacterial, hepatoprotective, analgesic, antimicrobial, antiulcer, and neuroprotective is present in edible flowers. The worldwide culinary and pharmaceutical industries are increasingly turning to edible flowers as a source of nutritionally rich ingredients, creating huge potential for the flower-based edibles market. Hence, the discovery of edible flowers has led to new opportunities for combating hunger, expanding agricultural production, creating new streams of revenue, and saving endangered species of wild flowers. Researchers focusing on edible flowers and their applications may find the current study a useful resource, as it covers a thorough understanding of all these issues.

Plants Used in the Management and Treatment of Male Reproductive Health Issues: Case Study of Benin People of Southern Nigeria

32

Matthew Chidozie Ogwu and Moses Edwin Osawaru

Contents

Abstract

Through an ethnomedicinal survey, this case study presents a list of medicinal plants used for male reproductive health care by the Benin people of Southern Nigeria and their associated ethnobotanical knowledge and practices. Information was obtained from randomly selected traditional healers, tradomedical practitioners, and native midwives from the main tribal groups within the cities using a semistructured open-ended questionnaire. A total of 30 medicinal plants belonging to 22 plant families were identified, documented including *Alchornea cordifolia, Aloe vera*, *Bambusa vulgaris, Calophyllum inophyllum, Cananga odorata, Carica papaya, Cassia alata*, *Cassia mimosoides*, *Chasmanthera dependens, Cissampelos mucronata, Cissus populnea, Citrullus vulgaris, Citrus*

S. C. Izah et al. (eds.), *Herbal Medicine Phytochemistry*, Reference Series in Phytochemistry, https://doi.org/10.1007/978-3-031-43199-9_56

aurantifolia, *Combretum racemosum, Cyathula prostrata*, *Cynodon dactylon, Diodia scandens, Musa paradisiaca*, *Nauclea latifolia, Newbouldia laevis*, *Parkia biglobosa*, *Plumeria rubra, Rauwolfia vomitoria, Sansevieria trifasciata, Secamone afzelii, Sida acuta, Solanum nigrum, Tectona grandis, Trianthema portulacastrum,* and *Zea mays*. These plants contribute to the cultural well-being of indigenous people and are used in the treatment of venereal diseases like gonorrhea and syphilis, impotency, genito-urethra disorders, cleansing of the genital tracks, boosting sexual appetite and performance (as an aphrodisiac), boosting sperm counts to address pre-testicular, lifestyle and post-testicular causes and factors of male infertility. The dominant plant families are Apocynaceae and Poaceae with three plant representatives each and followed by Rubiaceae, Menispermaceae, and Fabaceae with two representatives each. Together these dominant plant families account for 41.4% of plants encountered in the study. The parts of the plant used in the improvement of male fertility by the Benin people of Southern Nigeria include leaves, fruits, shoot and root, flowers, leaves and root, root and flowers, seeds, stem, whole plant, root and bark, and bark. The medicinal plants documented in this chapter would benefit from research and technological innovations. The vast knowledge and practices associated with medicinal plants need to be acknowledged and conserved not only through sustained local but also global efforts. The chapter contributes toward understanding, promotion, documentation, and safeguarding of indigenous knowledge, practices, and plant resources used in addressing male reproductive issues.

Keywords

Infertile men · Sperm count · Venereal disease · Traditional medicine · Benin people

1 Introduction

Traditional medicine is the earliest form and the only health care means available to many Nigerians. This medical approach is used to treat various communicable and noncommunicable human diseases/ailments such as cough, dysentery, insomnia, cardiovascular diseases, mental illness, and infertility. Male infertility is the inability of a man to impregnate a fertile female over a minimum period of 6 months to 1 year [39, 46]. Some reversible and irreversible underlying conditions that may cause male infertility include reduced sperm motility, semen abnormalities, genital tract infection, high scrotal temperature (varicocele) and testicular disorder, excess alcohol and drug use (like anabolic steroids, ranitidine, antidepressant, and cimetidine) and abuse of illegal drugs, disturbance to the endocrine, systemic disease, genetic abnormalities, obesity, immunological factors, etc. [27, 31–33, 75]. Recently, Turner et al. [78] described male infertility as a women's and societal health issue because of stigma, unequal burden-sharing, and lack of assisted reproductive technology for diagnosis.

Male infertility has resulted in so many breakdowns in marriages across the globe. This reproductive health issue is increasing globally with little to no concerted effort [27, 72]. This may not be unconnected to the poorly understood mechanisms that are linked to male infertility like environmental, psychological, genetical, and biochemical mechanisms [8, 9]. The major means for diagnosing male infertility is through semen characterization to detect abnormality in quantity, appearance, quality, vigor or motility, and concentration. Over the last 50 years, evidence has shown that sperm count has been on the decrease as a consequence of increases in male infertility. Infertile men typically fail to impregnate fertile females due to a lack of enough or deformed sperm with excess abnormal morphology. Also, other factors such as psychological factors, which include stress, depression, guilt, and low self-esteem generally, contribute to male infertility.

This chapter aims to produce an inventory of the plants used by the residents of Benin City Nigeria for addressing male reproductive and sexual health conditions. A focused approach was adopted and carried out along with a nonexperimental validation of the plants used through a literature review of the phytochemicals and pharmacological information supporting the medicinal activities. This chapter documents the traditional medicinal practices for improving male fertility as well as in the treatment and management of male fertility issues and enumeration of how these plants are used (i.e., either alone or in combination).

2 Global Infertility and Infertility in Men

A global pandemic caused by infertility will have socioeconomic and developmental consequences besides individual and public health impacts. Infertility has been linked to individual and communal psychological, physical, spiritual, economic, and sociocultural decline mainly due to the distress, depression, and anxiety of being infertile [73, 80]. Infertility is a global health, socioeconomic, and development issue with no standardized reporting format. The problem threatens not only physical health but can lead to a serious impact on the mental and social well-being of infertile couples. At the moment, developing countries are disproportionately affected by infertility and cases continue to show an upward trend due to insufficient fertility care, caregivers, and facilities in low-income countries as well as effectiveness and affordability where available [54, 55]. On the other hand, Borumandnia et al. [12] reported a downward trajectory in infertility in high-income and developed countries due to a low tendency of reproduction and a high number of infertility care facilities. Generally, about 40–45% of infertility in men is due to the “male factor” i.e., alteration or decline of sperm concentration, motility, or morphology [31]. The concept of male factor is hinged on sperm and sperm quality, which is typically used as a surrogate measure of male fecundity. It is estimated to affect about 15% of couples or around 48.5 million couples worldwide with males solely responsible for 20–30% and 50% of cases, respectively [2]. Infertility is considered lower in men than in women

Infertility may be primary (when pregnancy has never been achieved) or secondary (when at least one prior pregnancy has been achieved). Secondary infertility is the most prevalent form in women due to reproductive tract infections whereas primary infertility is more common in men depending on several complex factors [18, 37, 79]. Male infertility may be linked to:

1. Pre-testicular causes and factors
2. Lifestyle factors and causes
3. Post-testicular causes and factors

Pre-Testicular Causes and Factors. These are conditions that impede the production and transportation of sperm and include

- Hypogonadotropin hypogonadism (low testosterone).
- Undiagnosed and untreated coeliac disease.
- Medications (particularly chemotherapies).
- Severe injury or diseases like diabetes, HIV AIDS, thyroid-linked diseases, Cushing syndrome, heart attack, liver or kidney failure, impaired sperm production, and chronic anemia.
- Genetic abnormalities such as Robertsonian translocation.
- Sexually transmitted diseases that scar the male reproductive system, impair functions, and block sperm passage like repeated *chlamydia trachomatis,* and gonorrhea infections. Human papillomavirus (genital warts).
- Poor nutrition affects sperm quality and quantity.
- Environmental factors like occupational or long-term, intensive exposure to chemicals and toxins (e.g., agrochemicals like herbicides and pesticides, bisphenol A, phthalates, and organochlorines and heavy metals like lead, cadmium, or arsenic) that reduce sperm count and quality, testicular functions, or alters the endocrine systems.
- Varicoceles (i.e., the enlargement of testicular veins which transports oxygen-depleted veins out of the scrotum resulting in the inefficient circulation of blood out of the organ), which occurs in about 15% of men and around 40% of infertile men and results in increased testicular temperature, which affects sperm production, movement, and shape [32, 33].
- Aging can reduce the count, motility, and genetic quality of sperm. This is a gradual process of male fertility decline.

Lifestyle Factors and Causes. These are factors that cause physical and emotional stress, which have the potential to temporarily reduce male fertility especially sperm count and quality and erectile dysfunction. Some issues that have been linked to low sperm count and quality like:

- Testicular overheating due to high fevers, saunas, and hot tubs.
- Excessive use of drugs like cocaine, heroin, and marijuana.
- Heavy alcohol consumption.

- Excessive cigarette smoking.
- Prolonged bicycling exposes the perineum (i.e., the region between the scrotum and the anus) to extreme shocks, vibrations, and scrotal injuries.

Post-Testicular Causes and Factors. These are conditions that decrease male fertility after testicular sperm production like

- Genital tract and ejaculation defects (premature, delayed, or retrograde ejaculation).
- Obstruction of the seminal ducts or ejaculatory duct obstruction.
- Vas deferens obstruction or lack of vas deferens.
- Infection like prostatitis.
- Retrograde ejaculation.
- Ejaculatory duct obstruction conditions like aspermia, prostatic pain, oligo asthenospermia and azoospermia, painful ejaculation, and hematospermia [34].
- Hypospadias – urethra not located at the tip of the penis.
- Erectile dysfunction or impotence.

3 Plants Used in Male Reproductive Health Care: Case Study of Benin City, Southern Nigeria

A survey was carried out in the six Local Government Areas that make up Benin City, Edo State (6.34° N and 5.60° E; Fig. 1) and is occupied by Benin people of Southern Nigeria to document medicinal plants used in the treatment and management of male fertility issues. Benin City lies within the humid tropical rainforest zone of Nigeria but its vegetation has been heavily altered by anthropogenic activities and human population growth and is currently a mosaic of secondary forest [17]. The climate is monsoonal with two distinct seasons (dry and rainy season) with high rainfall (2000–3000 mm), temperature (20–40 °C), and average atmospheric humidity of 28% and with radiation of 1600 h per year [56, 57]. A detailed description of the study area including soil characteristics can be found in Osawaru et al. [60–66], Osawaru and Ogwu [58, 59], Ogwu and Osawaru [43].

The survey to document traditional medicine practices and higher plants used for male reproductive care by Benin people was conducted between July and November 2021 using survey sheets for information collection, a digital camera, an audio recording device for interviews, and a mobile phone-enabled position marker. The survey focused on randomly selected and locally identifiable professional herbalists, traditional healers, native midwives, and herbal remedy sellers using semistructured, open-ended questionnaires in English and/or preferred native languages. The randomly selected respondents and interviewees are duly registered with all the relevant authorities. The questionnaires were administered to the key informants (full-time traditional healers, part-time practitioners, elderly people who know the traditional values of the plants, relatives, and acquaintances who at one time or the other used some of these plants for male reproductive health and fertility). The respondents

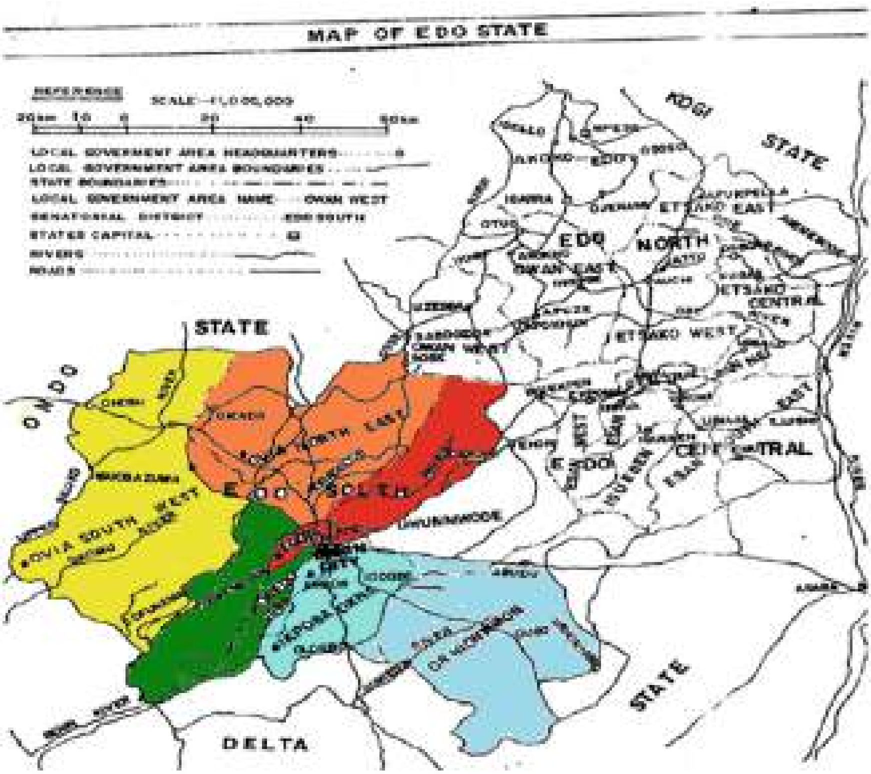

Fig. 1 Map of Edo State with the sampling area highlighted

animated a field survey to identify and collect plants and plant parts used for the treatment and management of male infertility and reproductive care. Specific questions like the botanical names, local names, plant parts used, dosage, method of preparation, application, and duration of treatment were asked during the oral interview, and the information supplied by these people was recorded. Collections were made from homestead farms, distant farms, and different forests present in the study area.

Data collected include the sociodemographic characteristics of the respondents (gender, age, marital status, educational qualification, religion, tribe/ethnic group, occupation, name of village, and languages spoken), and information on the plants used for the treatment and management of male infertility and preparation of herbal remedies for reproductive care. Data collected were processed and analyzed using Windows Microsoft Excel 2016 version software, which was also used to draw charts to understand inherent patterns. The therapeutic importance of each identified species was also recorded. Based on the knowledge of the informants, a total of 30 medicinal plants used for the treatment and management of male infertility were identified by a taxonomist at the University of Benin.

3.1 Medicinal Plants Used by Benin People for the Treatment and Management of Male Infertility and Reproductive Healthcare

From the survey, a total of 30 medicinal plants belonging to 22 plant families were identified, documented, and collected as used by Benin people for the treatment and improvement of male fertility (Tables 1 and 2). The plants included *Alchornea cordifolia, Aloe vera*, *Bambusa vulgaris, Calophyllum inophyllum, Cananga odorata, Carica papaya, Cassia alata*, *Cassia mimosoides*, *Chasmanthera dependens, Cissampelos mucronata, Cissus populnea, Citrullus vulgaris, Citrus aurantifolia*, *Combretum racemosum, Cyathula prostrata*, *Cynodon dactylon, Diodia scandens, Musa paradisiaca*, *Nauclea latifolia, Newbouldia laevis*, *Parkia biglobosa*, *Plumeria rubra, Rauwolfia vomitoria, Sansevieria trifasciata, Secamone afzelii, Sida acuta, Solanum nigrum, Tectona grandis, Trianthema portulacastrum,* and *Zea mays* (Table 1). They are used for treatment of venereal diseases like gonorrhea and syphillis, impotency, genito-urethra disorders, cleansing of the genital tracks, boosting sexual appetite and performance (as an aphrodisiac), and boosting sperm counts (Table 1). Hence, the plants can be used to address pre-testicular, lifestyle, and post-testicular causes and factors of male infertility in line with the reports of Roozbeh et al. [74] and Boroujeni et al. [11]. For greater contribution in addressing global male infertility issues, the active agents in these plants require a collaborative effort to isolate them as a prodrug candidate and elucidation at the molecular, cellular, and clinical levels to understand their mechanism of action [1, 28]. The plant families encountered in this study included Amaranthaceae, Annonaceae, Apocynaceae, Asparagaceae, Bignoniaceae, Caesalpinioideae, Calophyllaceae, Caricaceae, Combretaceae, Cucurbitaceae, Euphorbiaceae, Fabaceae, Lamiaceae, Liliaceae, Malvaceae, Menispermaceae, Musaceae, Poaceae, Rubiaceae, Rutaceae, Solanaceae, and Vitaceae (Table 2). The dominant plant families are Apocynaceae and Poaceae with three plant representatives each and followed by Rubiaceae, Menispermaceae, and Fabaceae with two representatives each (Table 2). Together these dominant plant families account for 41.4% of plants encountered in the study.

Plants possess medicinal value in addition to their nutritional importance [40–42]. From time immemorial, plants and plant extracts have been used medicinally in all parts of Nigeria especially as fertility agents without producing apparent toxic effects [39, 53]. This is backed by the report of D'Cruz et al. [16] wherein they opined that plant medicine is safe for addressing male reproductive dysfunction and other illnesses such as cancer and diabetes. Generally, there is a paucity of data and information on the safety of herbal medicine products and practices compared to modern medicine [22, 38, 69]. Where data exist, variations exist in terms of the significant toxic effect of medicinal plants on the reproductive system. The work of Nozhat et al. [38] using spearmints (Mentha spicata) suggests the absence of significant toxic effects on the reproductive system. However, toxic levels of heavy metals like cadmium, lead, arsenic, mercury, and copper have been reported in herbal medicines with significant geographical correlations in their concentrations

Table 1 Commonly used plants in the improvement of male fertility by the Benin people of Southern Nigeria

Scientific name	Family name	Common/Benin name	Parts used	Usefulness
Alchornea cordifolia	Euphorbiaceae	Christmas bush/Uwonwen	Leaves	To treat gonorrhea and other venereal diseases
Aloe vera	*Asphodelaceae*	Aloe vera/Aloe	Leaves	Treatment and management of impotency
Bambusa vulgaris	Poaceae	Bamboo/Ekpokoro	Young shoot	Treatment and management of gonorrhea and other venereal diseases
Calophyllum inophyllum	Calophyllaceae	Alexandrian laurel ball tree/ Ebe-ori	The kernel	Used in the treatment and management of gonorrhea and genito-urethra disorders
Cananga odorata	Annonaceae	Cananga tree\Erhan-uwa	Flower	Used for the treatment and management of impotency
Carica papaya	Caricaceae	Paw paw/Ughoro	Leaves and roots (used together)	For the treatment and management of venereal diseases and cleansing of the genital tracks
Cassia alata	Caesalpiniodeae	Candle bush/Asunwon	Root and flower	For the treatment and management of venereal diseases (specifically syphilis)
Cassia mimosoides	Fabaceae		Seed	It is used as an and to boost sexual performance
Chasmanthera dependens	Menispermaceae	Climbing plant/Aghoghon-ewaki	Root	A decoction made from it is taken to treat and manage gonorrhea.
Cissampelos mucronata	Menispermaceae	Abuta/Ewaki-nokhua	Leaves and roots	Leaves and roots are made into herbal juice and used as an aphrodisiac to boost sexual performance
Cissus populnea	Vitaceae	Bush mango/Iri-ogbono	Stem	Used for the treatment and management of venereal diseases
Citrullus vulgaris	Cucurbitaceae	Watermelon/Watermelon	Fruit	Fruits are eaten in large quantities as a remedy for urinary and genital tract problems arising from gravel and stone in the bladder
Citrus aurantifolia	Rutaceae	Lime/*Alimo-negiere*	Leaf	It is used to treat gonorrhea and urine retention
Combretum racemosum	Combretaceae	Christmas rose/Akoso-namwen	Root	It is used as an aphrodisiac

Cyathula prostrata	Amaranthaceae	Prostrate pasture weed/Ebe-ekperhon	Whole plant	Used for the treatment of gonorrhea
Cynodon dactylon	Poaceae	Stubborn grass/Iruvvba-ebo	Root	It is used in the treatment of secondary syphilis and irritated bladder
Diodia scandens	Rubiaceae	Not registered/Iyekegul	Leaf	It is used in treating venereal diseases
Musa paradisiaca	Musaceae	Plantain/Oghede	Root	Root juice is used to treat gonorrhea and urine retention; also, it is used in treating some other venereal diseases
Nauclea latifolia	Rubiaceae	African peach/Ero	Root and leaf	Roots and leaves are taken to improve male fertility
Newbouldia laevis	Bignoniaceae	Boundary tree/Ikhinmwin	Root with the leaves	It is used as an aphrodisiac and to boost sexual activities
Parkia biglobosa	Fabaceae	African locust bean/Ugbore	Seed	The seeds are used as an aphrodisiac
Plumeria rubra	Apocenaceae	Temple tree/Obadan-atori	The latex	Used for the treatment and management of venereal diseases
Rauwolfia vomitoria	Apocynaceae	The poison devil's pepper/Akata	The root bark	It is used as an aphrodisiac and to improve sexual performance
Sansevieria trifasciata	Asparagaceae	*Sansevieriatrifasciata*Prain/Asparagaceae	Leaf	It is used in the treatment of sexual weaknesses and to improve sexual performance
Secamone afzelii	Apocynaceae	Secamone/Iri -egile	Whole plant	It is used to cure venereal diseases like gonorrhea
Sida acuta	*Malvaceae*	Wire weed/Aranrenvbi	Seed	Used for the treatment and management of gonorrhea
Solanum nigrum	*Solanaceae*	European black nightshade/Ebeakpe	Leaf	The leaf juice is used for the treatment of gonorrhea
Tectona grandis	Lamiaceae	Teak/Ovbiakke	Bark	It is used as an aphrodisiac agent
Trianthema portulacastrum	*Aizoaceae*	Desert horse purslane/Eyen	Whole plant	Used for the treatment and management of gonorrhea and other sexual infections
Zea mays	Poaceae	Corn/oka	Seed	Roasted or boiled seeds are taken as an aphrodisiac to improve sexual performance and boost sperm count

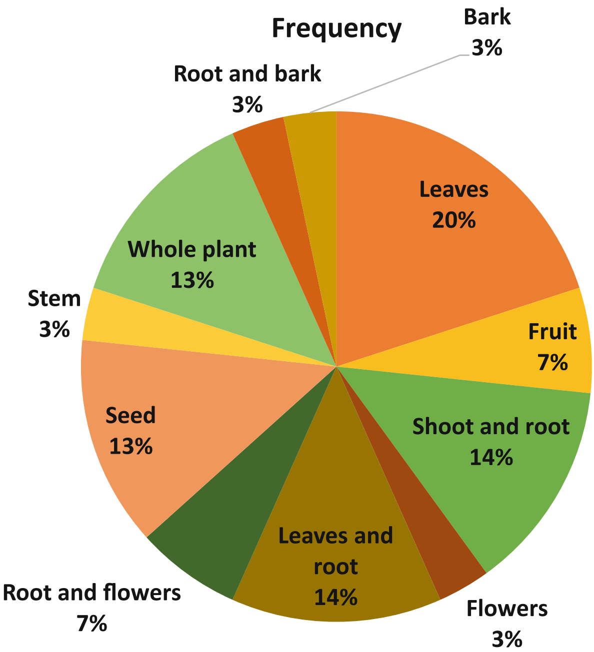
[7, 25, 36]. The use of these plants and herbal medicine products that contain their extract poses long-term health (cancer) risks [53].

In recent times, the use of plant and plant extracts for male fertility healthcare is on the increase because of the shifting attention from synthetic drugs to natural plant products [44, 45, 47–49]. Some of these plants are used to address sexual hormonal imbalances in males and females. Phytochemical screening of medicinal plants supports the presence of bioactive materials that can affect the regulation of conception and reproduction [20, 81]. Idu and Onyibe [26] documented a total of 300 plants belonging to 274 genera and from 77 families for the treatment of various illnesses, and among those plants listed includes those used in the promotion of male fertility among the people of Edo state. Trial and error play a huge role in the initial discovery and use of these medicinal plants for the treatment and management of male fertility issues. For instance, one or more plants are first used in the treatment or management of a single ailment (e.g., gonorrhea and some other venereal diseases) and then if the patient does not get relief from the plant within a specified period, another plant is tried, secondly, if the desired plant cannot be found on a specified time, another plant is taken as a substitute. The parts of the plant used in the improvement of male fertility by the Benin people of Southern

Table 3 Frequency of plant parts used in the improvement of male fertility by the Benin people of Southern Nigeria

Plant part	Frequency	Relative percentage
Leaves	6	20
Fruits	2	6.67
Shoot and root	4	13.33
Flowers	1	3.33
Leaves and root	4	13.33
Root and flowers	2	6.67
Seeds	4	13.33
Stem	1	3.33
Whole plant	4	13.33
Root and bark	1	3.33
Bark	1	3.33

Fig. 2 Percentage of plant parts used



Nigeria include leaves, fruits, shoot and root, flowers, leaves and root, root and flowers, seeds, stem, whole plant, root and bark, and bark but the most commonly used parts are the leaves (20%), seeds (13.33%), whole plant (13.33%), leaves and root (13.33%), and shoot and root (13.33%) (Table 3 and Fig. 2). This finding is supported by the reports of Jaradat et al. [28] wherein seeds, roots, and leaves were used for infertility treatment.

3.2 Enumeration of Medicinal Plants Used by Benin People for the Treatment and Management of Male Infertility and Reproductive Healthcare

3.2.1 *Alchornia cordifolia* (Common Name – Christmas Bush and Native Name – Uwonwen)

Alchornea cordifolia, is an evergreen dioecious shrub or small tree found almost throughout tropical Africa and has fleshy seeds (Fig. 3).

PLANT PART USED: Leaves.

FOLK USE: To treat gonorrhea and other venereal diseases and is supported by the work of Boniface et al. [10]. The phytochemical constituent of the plant has significant bioactivity and a high therapeutic value.

PREPARATION OF REMEDY: It is either macerated or chewed.

DOSAGE: Not specified.

3.2.2 *Aloe vera* (*A. barbadense*) (Common Name Aloe Vera)

The plant is a cactus-like succulent perennial with strong and fibrous roots and numerous, persistent, fleshy leaves, proceeding from the upper part of the root, tapering, thick, and usually beset at the edges with spiny teeth. They can be easily cultivated especially in tropical and subtropical regions of the world. Many of the species are branching and can grow up to about 30–60 feet in height with stems as much as 10 feet in circumference (Fig. 4).

Fig. 3 *Alchornea cordifolia*

Fig. 4 *Aloe vera*

PLANT PART USED: Leaf.

FOLK USE: It is used to treat and manage impotency and to improve sperm count, motility, and other characteristics. The plant can increase testosterone levels and sperm quality and quantity [23, 52].

PREPARATION: The leaf is made into juice and taken with water.

DOSAGE: To be taken twice daily.

3.2.3 *Bambusa vulgaris* (Common Name – Bamboo, and Native Name – Ekpokoro)

The plant forms moderately loose clumps and has lemon-yellow culms (stem) with dark green leaves. The culms are not entirely straight, not easy to split, inflexible, thick-walled, and strong. The densely tufted stems can grow up to 20 m high and 10 cm thick across the base. They can be cultivated and found in the wild (Fig. 5).

PLANT PART USED: Young tender shoot.

FOLK USE: Taken to cure gonorrhea and other sexually transmitted diseases. It is used to improve reproductive vigor.

PREPARATION OF REMEDY: Shoot extract is soaked in alcohol for several days.

DOSAGE: Two shots twice a day.

3.2.4 *Calophyllum inophyllum* (Common Name – Alexandrian Laurel Ball Tree, and Native Name – Ebe-Ori)

Calophyllum inophyllum is a large evergreen plant that can grow up to 60 m tall and found in tropical regions of the world. It is a low-branching and slow-growing tree

Fig. 5 *Bambusa vulgaris*

Fig. 6 *Calophyllum inophyllum*

with a broad and irregular crown glossy oval-shaped leaves, scented flowers, and round green fruits. It usually reaches 8–20 m in height (Fig. 6).

PLANT PART USED: The fruit/kernel. Oil is produced from the kernel for use in male reproductive health.

FOLK USE: Used in the treatment of gonorrhea and genito-urethra disorders like swelling and wounds. The kernels are naturally antiseptic and anti-inflammatory [13, 70].

PREPARATION FOR USE: The kernel oil is gotten.
DOSAGE: One spoon full three times daily.

3.2.5 *Cananga odorata* (Common Name – Canaga Tree, Native Name – Erhan-Uwa)

Cananga is a fast-growing tropical tree that originates in Southeast Asia (Indonesia, Malaysia, and the Philippines) and can grow above 5 m per year. The evergreen leaves are smooth and glossy, oval, pointed, and with wavy margins and 13–20 cm long. The scented flower is drooping, long-stalked with six narrow, greenish-yellow petals (Fig. 7).

PLANT PART USED: Flowers.
FOLK USE: Cures impotency. It may be used as a male contraceptive because of its anti-spermatogenic effects [19].
PREPARATION OF REMEDY: Decoction prepared from the flowers.
DOSAGE: Two shots twice daily (morning and evening).

3.2.6 *Carica papaya* (Common Name – Paw Paw or Papaya and Native Name – Ughoro)

Papaya has a single stem growing and can reach 10 m tall, with spirally arranged leaves at the top of the trunk. The lower trunk is conspicuously scarred to mark where previous leaves and fruits were borne. The large leaves may reach 70 cm in diameter and contain a significant amount of antioxidants (Fig. 8).

Fig. 7 *Cananga odorata*

Fig. 8 *Carica papaya*

PLANT PART USED: The leaves and roots are used together.

FOLK USE: Treatment of gonorrhea and other venereal diseases. The leaves can be used as an aphrodisiac to boost libido as well as functional sterility as a contraceptive [15, 30, 35].

PREPARATION OF REMEDY: Infusion of the green leaves and roots.

DOSAGE: Three times daily (half a glass cup).

3.2.7 *Cassia alata* (Common Name – Candle Bush And Native Name – Asunwon)

Cassia alata is a shrub that can reach 4 m in height with pinnate leaves that are between 50 and 80 cm long. The leaves close in the dark while the yellow inflorescence looks like a candle. The fruits are borne in a straight pod that is approximately 25 cm long while the seeds are dispersed by water and animals (Fig. 9).

PLANT PART USED: The root and flower.

FOLK USE: For the treatment and management of venereal diseases (like syphilis). It also has hormone-boosting functions [50, 51, 77].

PREPARATION POF REMEDY: The leaves and roots are made into powder and mixed with lime.

DOSAGE: Two shots are taken twice daily.

3.2.8 *Cassia mimosoides* (Common Name – Senna Tea)

It is a low-lying to an upright diffuse shrub that can grow up to 1.5 m or more in height. The pinnate leaves are 7–10 cm long, with 40–60 pairs of narrow leaflets, and a solitary, sessile glind on the ranchis below the leaflets. Flowers grow one or two

Fig. 9 *Cassia alata*

Fig. 10 *Cassia mimosoides*

together in the axils of the leaves. Shining, small, and yellow. Pods are strap-shaped, flat, and about 5 cm long, containing rhomboid, dark-brown seeds (Fig. 10).

PLANT PART USED: Seed.

FOLK USE: Aphrodisiac to boost sexual appetite and performance and increases fertility by improving sperm characteristics.

PREPARATION OF REMEDY: Seed extract is made.
DOSAGE: Taken twice daily (half of a glass cup).

3.2.9 *Chasmanthera dependens* (Common Name – Climbing Plant And Native Name – Aghoghon-Ewaki)

The plant is a woody climber (liana) in dense evergreen or semi-deciduous lowland forest and riparian woodland of the drier Guinean zone from Sierra Leone to Nigeria, and Cameroun across Ethiopia and Somalia. They may be propagated through their seeds. The roots and leaves are considered edible (Fig. 11).

PLANT PART USED: Root.
PREPARATION OF REMEDY: Decoction prepared with root or root extracts and soaked in alcohol.
FOLK USE: The decoction is taken to treat venereal diseases like gonorrhea. It has fertility-enhancing functions and androgenic activities [21, 71].
DOSAGE: One shot is taken three times per day.

3.2.10 *Cissampelos mucronata* (Common Name – Abuta and Native Name – Ewaki-Nokhua)

Cissampelo smacronata is a liana with woody rootstock in tropical Africa. The leaves are subpeltate, ovate-cordate, and covered in grayish indumentum, mucronate at the apex, flower axillary, or in false racemes (Fig. 12).

PLANT PART USED: The leaves and roots are used.
PREPARATION OF REMEDY: The leaves and roots are made into juice for the preparation of bitter tonic.

Fig. 11 *Chasmanthera dependens*

Fig. 12 *Cissampelos macronata*

FOLK USE: For the treatment of genital-urinary diseases.
DOSAGE: Half of a glass cup twice daily.

3.2.11 *Cissus populnea* (Common Name – Bush Mango and Native Name – Iri-Ogbono)

Cissus populnea is a strong woody liana, 8–10 m long, 7 cm in diameter, dispersed generally throughout the region from the coast to the Soudanian and Sahelian woodland, of Nigeria (Fig. 13).

PLANT PART USED: Stem.
FOLK USE: Treatment of venereal diseases.
PREPARATION OF REMEDY: The decoction of the stem is mixed with the decoction prepared with *Alchornea cordifolia* root. It improves sperm quality and quantity and may be used as an aphrodisiac to enhance sexual performance [5, 50].
DOSAGE: One shot is taken twice daily (morning and evening).

3.2.12 *Citrullus vulgaris* (Common Name – Water Melon)

Citrullus vulgaris is a vine-like flowering plant originally from the Southern parts of Africa but is commonly cultivated in Central and Northern Nigeria. it is a large, sprawling oval-shaped annual plant with coarse, hairy pinnately lobed leaves and white to yellow flowers that are grown mainly for the edible fruit, which is considered a berry, botanically. The fruit is a smooth hard rind, usually green with light to dark green stripes or yellow spots, and a juicy, sweet interior flesh, usually deep red to pink, but sometimes orange, yellow, or white, with many seeds (Fig. 14).

Fig. 13 *Cissus populnea*

Fig. 14 *Citrullus vulgaris*

PLANT PART USED: Fruit.

FOLK USE: The fruit is eaten in large quantities because the pulp is considered a remedy for the urinogenital problems arising from gravel and stone in the bladder. It is considered a genital cleanser. It is believed to enhance sperm motility and kinetics [29].

PREPARATION OF REMEDY: No definite preparation. It depends on the user and is often preferred fresh or made into a juice.
DOSAGE: Not specified.

3.2.13 *Citrus aurantifolia* (Common Name – Lime and Native Name – Alimo-Negiere)

Citrus aurantifolia is a shrubby tree with many thorns. It can be grown indoors and the leaves are harvested regularly for use in the treatment and management of male reproductive issues. The trunk rarely grows straight and has many branches. The leaves are ovate and resemble orange leaves. The flowers are about 2.5 cm in diameter and are yellow-white with a light purple tinge on the margins. Flowers and fruit may be seen on the plant throughout the year, but are mostly abundant in the early rainy season in Nigeria (Fig. 15).

PLANT PART USED: Leaves.
FOLK USE: Taken to treat gonorrhea and urine retention problems. The high amount of antioxidants in the plant has a positive effect on male fertility [3].
PREPARATION OF REMEDY: Hot decoction of the leaves is prepared with water.
DOSAGE: Half a glass cup is taken three times daily.

3.2.14 *Combretum racemosum* (Common Name – Christmas Rose and Native Name – Akoso-Namwen)

It is a shrubby liane with opposite or subopposite leaves. It is common in West Africa and other wet tropical biomes (Fig. 16).

Fig. 15 *Citrus aurantifolia*

Fig. 16 *Combretum racemosum*

PLANT PART USED: The root.

FOLK USE: It is used as an aphrodisiac to improve sexual performance and appetite. Its root is known to help with infections.

PREPARATION OF REMEDY: The root is soaked in alcohol and the extract is obtained.

DOSAGE: One shot is taken three times per day.

3.2.15 *Cyathula prostata* (Common Name – Prostrate Pasture Weed and Native Name – Ebe-Ekperhon)

It is an annual to perennial erect or ascending herb that may grow up to 50 cm in height. The roots appear at the nodes while the stem is obtusely quadrangular, thickened above the nodes, often tinged with red, and covered with patent and fine hairs. The leaves are oppositely arranged, simple, and rhomboid obovate to rhomboid-oblong form and vary in size between. The inflorescence is an erect elongated raceme, terminal and in highest leaf-axis and dull pale green, hairless within and eternally clothed with patent long and white hairs. The fruit is an ellipsoid utricle, thin-walled, hairless, one-seeded, and surrounded by stiff perianth (Fig. 17).

PLANT PART USED: Whole plant.

FOLK USE: Used for the treatment of gonorrhea and other venereal diseases. It is also taken to improve sexual performance and sperm production [4]. Male sexual problems connected to obesity are treated or managed using the plant [24].

PREPARATION OF REMEDY: Decoction of the whole plant is made using water.

DOSAGE: Half a glass cup is taken three times daily.

Fig. 17 *Cyathula prostata*

3.2.16 *Cynodon dactylon* (Common Name – Stubborn Grass, Bermuda Grass, and Native Name – Iruvvba-Ebo)

The blades are gray-green and short, usually 2–5 cm long with rough edges. It is a low-statured and creeping perennial found in almost all tropical and subtropical regions. The erect stems can grow up to 30 cm tall and are slightly flattened, and often tinged purple. The seeds are produced in a cluster of six spikes at the top of the stem. It has a deep root system. The grass creeps along the ground and roots wherever a node touches the ground, forming a dense mat (Fig. 18).

PLANT PART USED: Root.

FOLK USE: It is used in the treatment of secondary syphilis and irritated bladder. It is effective in remediating stress-induced male sexual dysfunction and is believed to be a potent aphrodisiac [14].

PREPARATION OF REMEDY: Root decoction is made and soaked in water or alcohol.

DOSAGE: Two tea cups are taken per day.

3.2.17 *Diodia scandens* (Common Name – Sarmentosaswart and Native Name – Iyekegul)

Straggling, scrambling, or procumbent, often with many lateral branches from the main stem and compound leaves. The leaf blades are yellowish green, elliptic, apex, narrow to the base, and scabrid above with dense very short to longer tubercle-based hairs. Leaves are scabrid and jungle-thicket-like (Fig. 19).

Fig. 18 *Cynodon dactylon*

Fig. 19 *Diodia scandens*

PLANT PART USED: Leaf.
FOLK USE: it is used in treating venereal and urinogenital diseases.
PREPARATION OF REMEDY: Leaf decoction is prepared.
DOSAGE: Not specified.

3.2.18 *Musa paradisiaca* (Common Name – Plantain and Native Name – Oghede)

Musa paradisiaca is a large and fast-growing evergreen perennial monocotyledonous plant that can reach 9 m tall when mature. The above-ground part of the plant is a false stem or pseudostem and consists of leaves that are huge and paddle-like. Each pseudostem can produce a single flowering stem. After fruiting, the pseudostem dies, but an offshoot may develop from the base of the plant (Fig. 20).

PLANT PART USED: Root.

FOLK USE: The root juice is used to treat gonorrhea and urine retention; also, it is used in treating some other venereal diseases. It has an enhancing effect on male reproductive functions and semen quality [6].

PREPARATION OF REMEDY: Juice is made from the root.

DOSAGE: Three shots should be taken daily (morning, afternoon, and evening).

3.2.19 *Nauclea latifolia* (Common Name – African Peach and Native Name – Ero)

Nauclea latifolea is a deciduous shrub or tree with an open canopy, usually branching from low down the bole, and can reach 30 m in height depending on soil and moisture conditions. The edible fruit is gathered from the wild for local use (Fig. 21).

FOLK USE: For general male fertility and improving sexual performance.

PLANT PART USED: Root and leaves.

Fig. 20 *Musa paradisiaca*

Fig. 21 *Nauclea latifolia*

PREPARATION OF REMEDY: It is prepared by making a decoction from the root and the leaf and is typically soaked in alcohol.

DOSAGE: One glass cup is taken twice daily.

3.2.20 *Newbouldia laevis* (Common Name – Boundary Tree and Native Name – Ikhinmwin)

Newbouldia laevis is a fast-growing evergreen shrub or small tree. It only reaches a height of 8 m in the west within its range but can attain a height of up to 20 m in the east. The bole can be up to 90 cm in diameter, but it is usually less (Fig. 22).

PLANT PART USED: Root with the leaves.

FOLK USE: It is an aphrodisiac in action. It is also used to address a hormonal imbalance in men for fertility enhancement.

PREPARATION OF REMEDY: Root with leaves soaked in either palm wine or dry gin.

DOSAGE: About half a glass cup three times daily if soaked in alcohol (less than 40% alcohol) or one shot three times daily if soaked in dry gin (about 40% alcohol).

3.2.21 *Parkia biglobosa* (Common Name – African Locust Bean and Native Name – Ugbore)

Parkia biglobosa is a perennial deciduous semi-cultivated tree that can reach 20 m in height or some cases, up to 30 m. It provides a canopy for several plants that grow within its shade. The tree is considered to be fire resistant (heliophyte) and is characterized by a thick dark gray-brown bark. It has a dense spreading umbrella-

Fig. 22 *Newbouldia laevis*

Fig. 23 *Parkia biglobosa*

shaped crown and a cylindrical trunk. The pods are referred to as locust beans and are pinkish in the beginning but later turn dark brown when fully mature. Each pod can contain up to 30 seeds (Fig. 23).

PLANT PART USED: Seeds.
FOLK USE: The seeds are aphrodisiacs and improved sperm quality and quantity.
PREPARATION OF REMEDY: To be chewed.
DOSAGE: Not specified.

Fig. 24 *Plumera rubra*

3.2.22 *Plumeria rubra* (Common Name – Temple Tree and Native Name – Obadan-Atori)

Plumera rubra is a deciduous shrub or small tree that grows up to a height of 2–8 m. It has a thick succulent trunk and sausage-like branches that are covered with a thin gray bark. The branches are brittle and when broken, ooze a white latex that can be irritating to the skin and mucous membranes. The large green leaves can reach 50 cm long and are arranged alternately and clustered at the end of branches. The flowers are terminal, appearing at the end of the branches over the summer (Fig. 24).

PLANT PART USED: The latex from the bark.
FOLK USE: For the treatment of venereal diseases like syphilis and gonorrhea. The plant is believed to have a regulatory function on fertility [76].
PREPARATION OF REMEDY: The latex tapped from the bark.
DOSAGE: A very small dosage of about 0.2 g to 0.3 g is taken and not more than that is recommended for use.

3.2.23 *Rauwolfia vomitoria* (Common Name – Devil's Pepper and Native Name – Akata)

Rauwolfia vomitoria is a shrub or small tree that grows up to 8 m in height all over West Africa. The older part of the plant contains no latex, unlike the younger parts. The branches are whorled and the nodes are enlarged and lumpy. Leaves are in threes, elliptic-acuminate to broadly lanceolate. Flowers are minute and sweet-scented, and branches of the inflorescence are distinctively puberulous with hardy-free corolla lobes. Fruits are fleshy and red (Fig. 25).

Fig. 25 *Rauwolfia vomitoria*

PLANT PART USED: Root bark.

FOLK USE: It is used as an aphrodisiac. It is used to address stress-induced infertility issues in men and to improve fertility.

PREPARATION OF REMEDY: The root back is soaked in gin.

DOSAGE: One shot is taken twice daily.

3.2.24 *Sansevieria trifasciata* (Common Name – Viper's Bowstring Hemp and Native Name – Erhurhue-Ekpen)

The plant is an evergreen perennial plant and forms dense stands that are spread by way of its creeping rhizomes, which are sometimes above ground. Its stiff leaves grow vertically from a basal rosette. Mature leaves are dark green with light gray-green cross-banding and usually range between 70 cm and 90 cm long and 5 cm and 6 cm wide (Fig. 26).

PLANT PART USED: Leaf.

FOLK USE: It is used in the treatment of sexual weakness and is considered an aphrodisiac. Used to maintain sexual rigor and improve performance.

PREPARATION OF REMEDY: Decoction of the leaf with *Piper guineensis.*

DOSAGE: About half a glass cup is taken twice daily.

3.2.25 *Secamone afzelii* (Common Name – Secamone and Native Name – Iri -Egile)

It is a scandent creeping woody shrub or climber, of secondary jungle and savanna thickets, common on unkempt farmland and in boundaries. It has compound leaves (Fig. 27).

Fig. 26 *Sansevieria trifasciata*

Fig. 27 *Secamone afzelii*

PLANT PART USED: Whole plant.
FOLK USE: It is used to cure venereal diseases like gonorrhea and improve fertility.
PREPARATION OF REMEDY: Decoction is prepared using the whole plant.
DOSAGE: The whole plant is used to cook light-boiled soup and is eaten together with the soup.

Fig. 28 *Sida acuta*

3.2.26 *Sida Acuta* (Common Name – Wire Weed and Native Name – Aranrenvbi)

It is an undershrub, with mucilaginous juice, aerial, erect, cylindrical, branched, solid, and green. The leaves are alternate, simple, lanceolate to linear, rarely ovate to oblong, obtuse at the base, acute at the apex, coarsely and remotely serrate, and the petiole is shorter than the blade. The inflorescence is a racemose (Fig. 28).

PLANT PART USED: The seeds.
FOLK USE: It is used for treating venereal diseases like gonorrhea.
PREPARATION OF REMEDY: Infusion of the seed is made.
DOSAGE: Not specified.

3.2.27 *Solanum nigrum* (Common Name – European Black Nightshade and Native Name – Ebeakpe)

It is a common herb or short-lived shrub, found in many wooden areas, as well as disturbed habitats. It can reach a height of 30–120 cm while the leaves average between 4 and 7.5 cm long and about 2 and 5 cm wide and are ovate to heart-shaped, with wavy or large-toothed edges, both surface hairy or hairless. The flowers have petals greenish to whitish (Fig. 29).

PLANT PART USED: Leaves.
FOLK USE: The leaf juice is used for the treatment of gonorrhea and other venereal diseases.
PREPARATION OF REMEDY: Juice prepared with or obtained from the leaves.
DOSAGE: Half of a glass cup is taken twice daily.

Fig. 29 *Solanum nigrum*

Fig. 30 *Tectona grandis*

3.2.28 *Tectona grandis* (Common Name – Teak and Native Name – Ovbiakke)

Teak is a large deciduous tree that measures up to 40 m tall with gray to grayish brown branches. Leaves are ovate-elliptic to ovate, 15–45 cm long by 8–23 cm wide, and are held on robust petioles that are 2–4 cm long. Leaf margins are entire (Fig. 30).

PLANT PART USED: The bark.

FOLK USE: It is used as an aphrodisiac agent to improve sexual appetite and performance.

PREPARATION OF REMEDY: The bark juice is commonly extracted with and soaked in alcohol.

DOSAGE: About half a glass cup is taken daily if extracted with palm wine but one shot three times daily if extracted with gin (about 40% alcohol).

3.2.29 *Trianthema portulacastrum* (Common Name – Desert Horsepurslane and Native Name – Eyen)

It is an annual herb forming a prostrate map or clump with stems up to a meter long. It is green to red, hairless except for small lines of hairs near the leaves, and fleshy. The leaves have small round or oval blades up to 4 cm long borne on short petioles. Solitary flowers occur in leaf axils (Fig. 31).

PLANT PART USED: The whole plant.
FOLK USE: Used for the treatment of gonorrhea.
PREPARATION OF REMEDY: The whole plant is dried and pulverized for use.
DOSAGE: Not specified but it is taken with cereals like pap (ogi).

3.2.30 *Zea Mays* (Common Name – Corn, Maize, and Native Name – Oka)

It is a vigorous annual grass, varying greatly in size according to race and growth conditions, culms, stout, often with prop roots from the lower nodes, many-noded, terminated by inflorescences of the male spikelet, and with one or more female spikelet in the axils of leaves below the tassel, leaf blade expanded, usually drooping, usually green (Fig. 32).

Fig. 31 *Trianthema portulacastrum*

Fig. 32 *Zea mays*

PLANT PART USED: The seeds.
FOLK USE: Taken to boost sperm count and as an aphrodisiac to boost sexual performance and appetite.
PREPARATION OF REMEDY: Grounded seeds are taken as pap or the seeds are roasted and consumed.
DOSAGE: Not specified.

4 Conclusion

The survey reported in this case study revealed 30 medicinal plants that are used by the Benin people of Southern Nigeria for promoting male fertility. The scientific, common, and indigenous names of the plants along with the parts used, dosage (where they exist), and the methods of preparation for the treatment and management of diverse male infertility issues were documented. The plants that were identified belong to 23 families. The survey revealed that Poaceae, Apocynaceae, Rubiaceae, Menispermaceae, and Fabaceae are the dominant plant families as they have the most plant representations with at least two plants within the family used to promote male fertility among Benin people. The mode or method of administration of the plant is entirely based on oral administration either by making a juice out of the plant, by making a decoction of the plant or by infusion of the plant. The various parts of the plant used are the plant leaf, the plant stem, the plant root, the plant seed, stem bark, root bark young shoot, and fruit juice. It is worth noting that the genetic diversity of medicinal plants is continuously in decline and is increasingly threatened by extinction due to human population exploitation, unsustainable harvesting and utilization techniques, loss of habitats, and unmonitored and unregulated trade in medicinal plants. These plants contribute to the culture and well-being of indigenous people together. Medicinal plants used to treat illnesses including fertility issues would benefit from research and technological innovations. The vast knowledge and practices associated with medicinal plants need to be acknowledged and conserved not only through sustained local but also global efforts. It is important to recognize the roles played by remote communities and indigenous people as custodians of the world's medicinal plant genetic heritage.

Plants Used in the Management and Treatment of Female Reproductive Health Issues: Case Study from Southern Nigeria

33

Moses Edwin Osawaru and Matthew Chidozie Ogwu

Contents

Abstract

Through an ethnomedicinal survey, this case study presents a list of medicinal plants associated with female fertility, pre- and postnatal care among Benin and Warri residents in Southern Nigeria, and their associated ethnobotanical knowledge and practices. Information was obtained from randomly selected traditional healers, tradomedical practitioners, and native midwives from the main tribal groups within the cities using a semistructured open-ended questionnaire. A total of 24 medicinal plant species belonging to 21 families were of ethnomedicinal importance for female fertility, pre- and postnatal care of Benin and Warri

residents in Southern Nigeria. Some of the plants include *Psidium guajava, Pennisetum purpureum, Oenothera biennis, Aloe barbadensis, Asparagus racemosus, Gossypium hirsutum, Newbouldia laevis, Phyllanthus amarus*, and *Afrormosia laxiflora*. These plants were said to have activities against menopausal symptoms, hormonal effects, fertility, and anti-fertility effects as well as abortifacients, contraceptive efficacy, aphrodisiac properties, treating reproductive tract infections, postnatal complications, relieving uterine bleeding, etc. Herbs and trees are the most used growth forms whereas leaves and seeds are the most cited plant part used in most of the tradomedical remedy preparations. Most of the remedies were prepared from a single and/or multiple plant source with other ingredients. The chapter contributes toward understanding, promotion, documentation, and safeguarding of indigenous knowledge, practices, and resources used in addressing female reproductive issues.

1 Introduction

From time immemorial, man's life has always been dependent on plants around him, from which he draws all his basic needs [1–7]. Despite the effectiveness of chemically synthesized medicines, plants have been used medicinally in all civilizations [8, 9]. Medicinal plants contribute to the development of new pharmaceuticals to address new or existing medical issues including reproductive issues [10]. A large proportion of the Global South populace in rural and suburban areas including Nigerians rely on traditional or ethnomedicine for their primary health care due to the accessibility, availability, effectiveness, affordability, and inherent trust associated with it. This agrees with the view of CGSPS [11] that an estimated 85% of developing nations mainly use traditional health care systems. About 33% of Nigeria's population is classified as poor with women accounting for a substantial amount of the group and living in remote rural communities [12, 13]. According to WHO (2010) an estimated 25% of maternal deaths occur during pregnancy. Almost 20% of global maternal death happen in Nigeria with about 600,000 death and 900,000 near death mainly due to bleeding in pregnancy, infection, preeclampsia, eclampsia, and anemia in pregnancy [11, 14, 15]. Other issues include low access, inadequate, inefficient, and inappropriate reproductive health care system in Nigeria for the large youthful and reproductively active population [12, 14]. There is a need for high-quality care to maintain reproductive and sexual vigor as well before, during, and after pregnancy and childbirth.

Appropriate medical use of Nigeria's rich and diverse flora can contribute to addressing female reproductive health issues. For instance, *Alstonia boonei* stem bark and root and *Cymbopogon citrates* leaves that are used to treat fever and itching during pregnancy and epilepsy and *Bryophyllum pinnatum* leaves that is used to treat cough [9, 16–18]. *Ficus exasperata* is important for treating venereal diseases [16]. *Ocimum gratissimum* and *Vernonia amygdalina* are used by Usen people in Edo State Nigeria to boost immunity for mother and child after delivery and to regulate breast flow, respectively [5]. However, these medicinal plants are not isolated from the ongoing global biodiversity loss due to environmental change and anthropogenic activities as well as erosion of ethnomedicinal knowledge and practices that characterize the diverse ethnic groups of Nigeria [19–22]. The major issue connected to the erosion of ethnomedicinal knowledge and practices is the aging and death of the custodians of this knowledge, migration, and a lack of interest by the younger generation [8, 23, 24]. Put together, traditional medicine may be under threat. Confronted with illness and disease, early men discovered a wealth of useful therapeutic agents in the plant and this ageless system is still valuable today. The empirical knowledge and systems associated with medicinal substances in plants were and is still being passed on by oral tradition [5, 6, 25, 26].

This chapter aims to produce an inventory of the plants used by the residents of Benin and Warri for addressing female reproductive and sexual health conditions. A focused approach was adopted and carried out along with a nonexperimental validation of the plants used through a literature review of the phytochemical/pharmacological information supporting the medicinal activities. Here, we defined reproductive conditions and infertility according to Ogbe et al. [9] and Olooto et al. [27] as those that affect reproductive and sexual success as well as the prevention of conception and infertility as the inability to achieve pregnancy over 6–12 months despite adequate, intentional, and regular (i.e., about 3–4 times per week), unprotected sexual intercourse, respectively. Some causes of female infertility include leukorrhea, menopause, sexually transmitted infections (like chlamydia and gonorrhea), preexisting conditions (like malaria, HIV/AIDS, anemia, and malnutrition) abnormal menstrual cycles, faulty uterus and ovaries, menstrual disorder, and inappropriate lifestyles like excessive smoking and drinking that alter the hormonal pattern and ovulation [28–31]. Miscarriage (i.e., vaginal bleeding before 20 gestational weeks resulting in fetal abortion) is a common complication in pregnancies [32–34]. Prenatal health care help prepare for safe childbirth and parenthood and is beneficial for the survival of the mother, and prevents, detects, alleviates, and manages actual or potential health problems of the fetus and expectant mother. It is important to note that female genital mutilation increases the likelihood of complications during childbirth [35–37].

At present, there is little to no documentation of higher plants used for female fertility, pre- and postnatal care by Benin and Warri residents in Southern Nigeria. This chapter will document the traditional medicinal practices for female fertility, prenatal and postnatal of Benin residents and identify and evaluate how these plants are used (i.e., either alone or in combination).

2 Plants Used in Female Reproductive Health Care: Case Study of Benin and Warri Cities, Southern Nigeria

2.1 Methodology

Benin City is in Edo State (6.34° N and 5.60° E) and to the South is Delta State where Warri City is located (5.55° N and 5.77° E). Benin and Warri Cities lie within the humid tropical rainforest zone of Nigeria but their vegetation has been heavily altered by anthropogenic activities and human population growth and is currently a mosaic of secondary forest [9]. The climate is monsoonal with two distinct seasons (dry and rainy season) with high rainfall (2000 mm–3000 mm), temperature (20–40 °C) and atmospheric humidity and with radiation of 1600 h per year [38, 39]. A detailed description of the study area including soil characteristics can be found in Osawaru et al. [40]; Osawaru and Ogwu [41, 42]; Ogwu and Osawaru [43].

Survey to document traditional medicine practices and higher plants used for female fertility, prenatal and postnatal care by Benin and Warri residents was conducted between July and November 2021 using survey sheets for information collection, a digital camera, an audio recording device for interviews, and a mobile phone enabled position marker. The survey focused on randomly selected and locally identifiable professional herbalists, traditional healers, native midwives, and herbal remedy sellers using semistructured, open-ended questionnaires in English and/or preferred native languages. The randomly selected respondents and interviewees are duly registered with all the relevant authorities. The questionnaires were administered to the key informants (full-time traditional healers, part-time practitioners, elderly people who know the traditional values of the plants, relatives, and acquaintances who at one time or another used some of these plants for female fertility). The respondents animated a field survey to identify and collect plants and plant parts used for female fertility, prenatal and postnatal care. Specific questions like the botanical names, local names, plant parts used, dosage, method of preparation, application, and duration of treatment were asked during the oral interview, and the information supplied by these people was recorded. Collections were made from homesteads, distant farms, and different forests present in the study area.

Data collected include the sociodemographic characteristics of the respondents (gender, age, marital status, educational qualification, religion, tribe/ethnic group, occupation, name of village, and languages spoken), information on the plants used for female fertility, prenatal and postnatal care, and preparation of herbal remedies. Data collected were processed and analyzed using Windows Microsoft Excel 2016 version software, which was also used to draw charts and graphs to understand inherent patterns. The variables were presented as percentages. The therapeutic importance of each identified species was also recorded. Based on the knowledge of the informants, a total of 24 plants were identified and properly identified by a taxonomist at the University of Benin and through literature review.

2.2 Demographic Characteristics of Respondents

The demographic characteristic of the respondents and animators is presented in Table 1. There were more female (80%) compared to male (20%) respondents. The most dominant age category was 36–45 years (40%) and most respondents were married (66.67%) and had at least secondary school education (53.33%). Marital status, gender, culture, occupation, affordability, accessibility, and education level are major drivers for the practice, acceptance, and use of traditional medicine [44, 45]. Economic status is no longer a major determinant factor for the use of traditional medicine but techniques (like mind-body methods), spirituality, dietary practices, and comfort [46]. African traditional religion was the dominant religion of the professional herbalists, traditional healers, native midwives, and herbal remedy

Table 1 Demographic characteristics of respondents

Characteristics	Frequency	%
Gender

sellers surveyed in Benin and Warri Cities (Table 1). The religious affiliation documented in the survey is different from those reported in Curlin et al. [47] wherein it was reported that the majority of alternative medicine practitioners are most likely not to have any religious affiliation. However, they noted that these practitioners describe themselves as very spiritual and indirectly use religious beliefs in their dealings. On the other hand, higher spirituality and religious affiliation among contemporary medicine practitioners positively correlate with their acceptance to integrate alternative medicine into their practice [47]. This may be exploited in the Global South where religious affiliation is high among contemporary medicine practitioners to integrate and increase the relevance of traditional medicine practices for female fertility, pre- and postnatal care. A greater number of the preferential and concurrent use of herbal and contemporary medicine has been documented in parts of the Global South like Tamale, Northern Ghana [48]. According to Ngere et al. [49], this may be connected to the perceived sociocultural relevance of belief systems in disease etiology and diagnosis as well as caregiving and care reception in intervention formulation. In more developed countries, age and chronic diseases are the most important factors for accepting and using herbal medicines [50].

2.3 Medicinal Plants Used by Benin and Warri Residents for Female Reproductive Health Care by Benin and Warri Residents in Southern Nigeria

A total of 24 medicinal plants are used by Benin and Warri residents for the treatment and management of female reproductive issues. The 24 plants recorded from this survey are distributed into 21 families including Myrtaceae, Poaceae, Lamiaceae, Fabaceae, Apiaceae, and Lauraceae (Tables 2 and 3). The 24 plants included *Psidium guajava, Pennisetum purpureum, Oenothera biennis, Aloe barbadensis, Asparagus racemosus, Gossypium hirsutum, Newbouldia laevis, Phyllanthus amarus, Vitex agnus-castus, Portulaca oleracea, Afrormosia laxiflora, Agelaea obliqua, Alstonia boonei, Aneilema hockii, Apium graveolens, Brunfelsia splendida, Cucumeropsis mannii, Euphorbia deightonii, Heeria insignis, Macaranga barteri, Penianthus zenkeri, Persea americana, Azadirachta indica,* and *Carica papaya*. The diversity of the flora suggests the strength and diversity of reproductive health issues that may be treated with them and the wide variety of medicinal recipes [51]. Fasola [52] documented 61 plants from 32 families used in addressing female reproductive problems in Ibadan, Oyo State, Nigeria whereas Ogwu et al. [5] recorded 36 plant species belonging to 25 plant families in Usen Edo State, Nigeria. Joudi and Ghasem [53] and Ogwu et al. [5] reported the diverse uses of plants from three families – Asteraceae, Fabaceae, and Malvaceae for reproductive ailments. In the current study, Euphorbiaceae had the highest plant species representation followed by Myrtaceae. Tsobou et al. [54] recorded 70 plants from 37 families used in the treatment of reproductive ailments in Cameroon. In a similar study, Nduche et al. [55] documented 62 plant species from 41 families that are used in Ebonyi State, Nigeria to address fertility-related

Table 2 Plants used by Benin and Warri residents for the treatment of female fertility, prenatal and postnatal issues

S/No.	Collection source	Plant name	Family	Common name	Status	Cultivation status	Origin
1	Home garden	*Psidium guajava*	Myrtaceae	Guava	Not assessed	Cultivar	Exotic

Portulacaceae	1

issues. These reports agree with the submission by Gill [56] that Nigerian flora is invaluable to the health system care of Nigerians. Some medicinal plants have multi-curative abilities where they are used in the preparation of reproductive health remedies for multiple ailments and taken as infusions, decoctions, and powdering [52, 57]. In the present study, most of the plants documented were reported to be associated with more than one female reproductive health issue as a remedy. Nonetheless, these native plants are often neglected or underutilized albeit they possess a substantial amount of undescribed benefits [58, 59]. A significant proportion of the African populace uses traditional plants and traditional healers and elders to manage health issues including the treatment of reproductive health problems [54]. The knowledge and practice are deep-rooted in the sociocultural background of the locale [60]. In some cases, a blend of indigenous and modern scientific knowledge is adopted to address certain reproductive health problems [5].

When these plants are used for female reproductive care, they are prepared and used in the form of oral tinctures, macerations, concoctions, or infusions and applied topically in rare cases [61, 62]. The survey of Benin and Warri residents revealed that the plants were mostly used alone and are commonly soaked in hot water or gin or boiled in water to extract the bioactive constituents (Table 4). In some cases, the plant seeds are dried and then grinded. These plant parts contain bioactive

Table 4 Plants used by Benin residents for female reproductive care, the parts used (whether alone or in combination with other herbal remedies), and the mode of administration is presented

S/N.	Botanical name	Part used	Decoction means	Alone or in combination with	Mode of administration
1	*Psidium guajava*	Leaves and stems	Soaking in hot water or gin	Alone	Swallowed
2	*Pennisetum purpureum*	Leaf extract	Soaking in hot water or gin	Alone	Swallowed
3	*Oenothera biennis*	Seed oil extract	Soaking in hot water or gin	Alone or in combination with *Cocos nucifera*	External application and/or swallowed
4	*Aloe barbadensis*	Leaf extract	Used fresh	Alone	Swallowed or applied externally
5	*Asparagus racemosus*	Root extract	Soaking in hot water or gin	Alone or in combination with other plant extracts	Swallowed
6	*Gossypium hirsutum*	Leaf and seed extract	Soaking in hot water or carbonated soft drink	Alone	Swallowed
7	*Newbouldia laevis*	Leaf and stem bark	Soaking in hot water or gin	Alone	Swallowed
8	*Phyllanthus amarus*	Leaf extract	Soaking in hot water or gin	Alone or in combination with yam extract	Swallowed
9	*Vitex agnus-castus*	Leaf and stem	Soaking in hot water or gin	Alone	Swallowed
10	*Portulaca oleracea*	Leaf and stem	Soaked in gin	Alone	Swallowed
11	*Afrormosia laxiflora*	Leaf extract	Soaking in hot water or gin	Alone	Swallowed
12	*Agelaea obliqua*	Leaf extract	Soaking in hot water or gin	Alone	Swallowed
13	*Alstonia boonei*	Leaf extract	Soaking in hot water or gin	Alone	Swallowed
14	*Aneilema hockii*	Leaf extract	Soaking in hot water or gin	Alone	Swallowed
15	*Apium graveolens*	Leaf and seed extract	Soaking in hot water or gin	Alone or in combination with other herbal remedies	Swallowed
16	*Brunfelsia splendida*	Leaf extract	Soaking in hot water or gin	Alone	Chewed and swallowed
17	*Cucumeropsis mannii*	Seed extract	Dried and grinded	Alone and/or in combination with other herbal remedies	Swallowed

(continued)

Table 4 (continued)

S/N.	Botanical name	Part used	Decoction means	Alone or in combination with	Mode of administration
18	*Euphorbia deightonii*	Succulent stem	Used fresh	Alone	Swallowed
19	*Heeria insignis*	Leaf extract	Soaking in hot water or gin	Alone	Swallowed
20	*Macaranga barteri*	Leaf and seed extract	Soaking in hot water or gin. Seeds are grinded.	Alone and/or in combination with other herbal remedies	Swallowed
21	*Penianthus zenkeri*	Root, stems, and leaf extract	Soaking in hot water or gin	Alone and/or in combination with other herbal remedies	Swallowed
22	*Persea americana*	Seeds	Dried and grinded	Added to meals	Swallowed

24	*Carica papaya*	Seeds	Dried and grinded	Added to meals	Swallowed

polyphenolic compounds like isoflavones and flavonoids that confer beneficial reproductive health effects on women [63].

The plants used by Benin and Warri residents for female reproductive care and the parts used, whether alone or in combination with other herbal remedies, and the mode of administration is presented in Table 4. The most common plant part used is the leaf and they can be used alone or in combination with other local herbal remedies. The decoction made from the plants is more likely to be ingested than externally applied.

The commonly used plant part in the preparation of traditional medical remedies by Benin and Warri residents for the treatment and management of female reproductive health issues is presented in Fig. 1. Besides the whole plant, various plant parts are commonly collected and used in the preparation of herbal remedies including stem, bark, root, leaves, whole plant fruits, and seeds [6, 52, 64–66]. However, in the present study, leaves followed by leaves and seeds and leaves and stem bark were the most used parts, while root, stems and leaves, root, oil, and stem had the least usage. Other workers have made a similar observation regarding the plant parts that are most commonly used including Idowu et al. [67]; Thirupathy [68]; and Shosan et al. [69] wherein leaves were reported as the most used plant part for the treatment and management of reproductive issues. These leaves may be used alone or in combination with other plant parts in the preparation of traditional remedies [70]. In agreement with the finding of Tsobou et al. [54] most herbal remedies are prepared as a decoction. We also observed that all the plants were used as a decoction. The method of preparing the herbal remedy is diverse but in most cases are soaked in dry gin (approximately 40% alcohol) or boiled in hot water

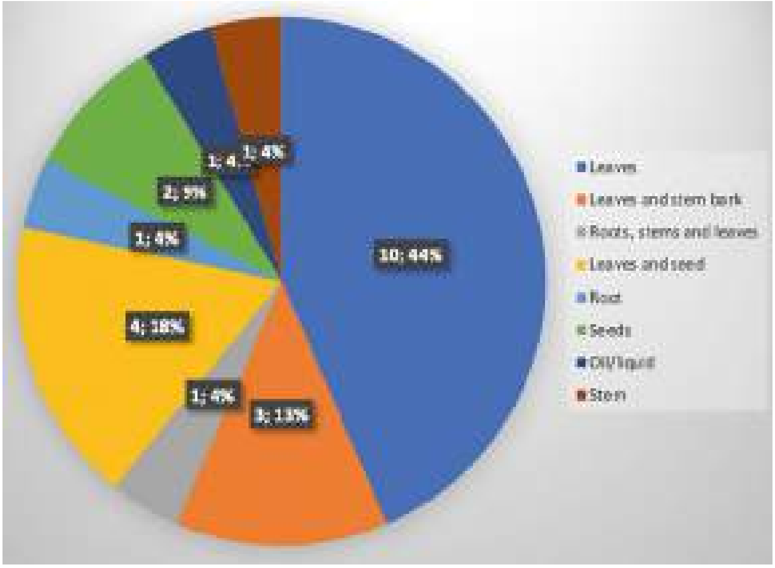

Fig. 1 Frequency of plant parts used for reproductive health care by Benin and Warri residents in Southern Nigeria

[6, 52, 71]. This work has highlighted the importance of plant-based medicine in female reproductive care, which is in line with the findings of Tsobou et al. [54] that medicinal plants are invaluable in the management of reproductive healthcare. Some of these plants used for female reproductive care have activities against menopausal symptoms, hormonal effects, fertility, and anti-fertility effects as well as abortifacients, contraceptive efficacy, aphrodisiac activity, reproductive tract infections, childbirth complications, and efficacy in relieving uterine bleeding, etc. Medicinal plants contain secondary metabolites that have important in vivo and in vitro functions to both ovarian folliculogenesis and steroidogenesis in many animal species [72].

2.4 Enumeration of Medicinal Plants Used for Female Reproductive Health Care by Benin and Warri Residents in Southern Nigeria

2.4.1 *Psidium Guajava* (Common Name – Guava)

It is a perennial evergreen tree. Flowering starts within the first 2 years and trees typically reach maturity after 5–8 years. Leaves are oppositely arranged while the fruit exudes a strong, sweet, musky odor when ripe and may be round, ovoid, or pear shape. The central pulp of the fruit is concolorous. Guava leaves are known to have attenuating effects on hypertension, hepatic steatosis, and other oxidative stress diseases because of their high oxidation activities [73–75].

Fig. 2 *Psidium guajava* leaves and fruits

Parts used: Leaves and stem bark. The leaves contain rutin, kaempferol, epicatechin, naringenin, isoflavonoids, gallic acid, and flavonoids [76].

Mode of administration: Tea made from leaves or bark is taken to regulate menstrual flow and pre-pregnancy stomach cleansing (Fig. 2).

2.4.2 *Pennisetum Purpureum* (Common Name – Elephant Grass)

A perennial grass that easily forms dense thickets with ecosystem-impacting characteristics functions especially on hydrology cycles, biophysical dynamics, and community composition. The plant has hormone-regulatory, antioxidant, and immune capacities as well as postpartum blood pressure management [77–79]. The decoction made from the plant is also used to manage menstrual pains and facilitate childbirth.

Parts used: Leaves.

Mode of administration: Young leaves are boiled and used in the treatment of venereal diseases preventing pregnancy and for superovulatory treatment as a hormonal control (Fig. 3).

2.4.3 *Oenothera Biennis* (Common Name – Evening Primrose)

A biennial plant that grows up to 1.2 m. It is not frost tender and flowers from June to September. The plant is hermaphrodite and is often polluted by Lepidoptera. The stem is hairy and often purple-tinged. Bright yellow, four-petaled flowers that open at night. The seed remains in the soil and germinates when the soil is disturbed. It is used in the treatment of mastalgia (breast pains) and hot flashes [80]. Hutcherson

Fig. 3 Mature *Pennisetum purpureum* plant

et al. [81] reported that using the plant decreases the risk of cesarean section, macrosomia, preeclampsia, and stillbirth. The plant is relevant for the cervical preparation of women about to undergo hysteroscopy [82].

Parts used: Oil extract from the plant.

Mode of administration: Used to improve sexual appetite, treat menopause symptoms, and regulate estrogen (Fig. 4).

2.4.4 *Aloe Barbadensis* (Common Name – Aloe Vera)

A succulent evergreen perennial that is stemless or short-stemmed and grows up to 60–100 cm. Leaves are thick and fleshy, green to gray-green. Leaf margins are serrated with small white teeth. The plant is used to treat internal and external injuries during pregnancy and after childbirth [83]. External application of aloe vera helps increase the sensitivity, elasticity, and functioning of reproductive organs and increases estrogen formation. Also, Maharjan et al. [84] connected the use of aloe vera gel to ovarian steroid restoration and protection.

Parts used: Leaves and leaf extract (juice).

Mode of administration: Leave and leaf extract are used to prepare juice and taken to improve ovary development, and follicle-stimulating hormones and to rejuvenate the uterus (Fig. 5).

2.4.5 *Asparagus Racemosus* (Common Name – Asparagus Grass)

Possess small pine-needle-like phylloclades that are mostly uniform and shiny green. The white flowers are short and spiky. Fruits are blackish-purple, globular berries. It has a tuberous adventitious root system that is about one meter in length and tapering at both ends. The plant is used to increase fertility and to address stress-related issues

Fig. 4 Mature *Oenothera biennis* plant with flowers

in pregnant women [85, 86]. It also has hormonal balancing effects in women, which increases the chances of pregnancy as well as lactation-boosting functions.

Parts used: Root extract.

Mode of administration: Extracts from the roots are used to balance female reproductive hormones (Fig. 6).

2.4.6 *Gossypium Hirsutum* (Common Name – Cotton)

The plant is an annual subshrub with alternate leaves, petiolate, palmately 3–5 lobed, hirsute, and cordate blades. Fruit is a dehiscent capsule (4–6 cm long), spherical smooth, light green, and bearing hairs on the epidermis strongly attached to the seed coat. Well-developed taproot with numerous lateral roots. A herbal remedy prepared from cotton regulates labor-inducing proteins and supports uterine quiescence [87]. The plant is also used to increase fertility and address health issues like fever, headaches, gastrointestinal problems, and nausea during pregnancy.

Fig. 5 Mature *Aloe barbadensis*

Fig. 6 *Asparagus racemosus*

Parts used: Leaves, seeds, and roots.

Mode of administration: Extracts from leaves and seeds are used in the treatment of menstrual disorders, symptoms of menopause, inducing labor, and afterbirth cleansing, and improve breast milk production. It is applied vaginally and on the breast surface (Fig. 7).

Fig. 7 *Gossypium hirsutum* leaves and flowers. (Source: Morris [88])

2.4.7 *Newbouldia Laevis* (Common Name – Boundary Tree, Akoko)

A perennial tree that grows up to 15 m high. The stem is woody. Each leaflet is oblanceolate 10–20 cm long and 5–10 cm broad, serrated, sessile, or with short petioles. The fruit is a long, pendulous, dehiscent capsule about 30 cm long dotted with glands. The plant leaves have uterine contractile effects and antihemorrhagic functions [89, 90]. It is also used to treat fever during pregnancy.

Parts used: Leaves and bark.

Mode of administration: Leaves are squeezed in water and applied in the virginal to stop bleeding in threatened miscarriage. The leaves are cooked and eaten by pregnant women to facilitate safe and easy delivery and milk production after birth. The barks are used to prepare a solution and used to treat stomach pains and cleanse the stomach in preparation for childbirth (Fig. 8).

Fig. 8 *Newbouldia laevis* leaves. (Source: Nwokolo [91])

2.4.8 *Phyllanthus Amarus* (Common Name – Sleeping Plant, Indian Gooseberry Plant, Seed under Leaf)

A slender annual herb with an erect stem and leafy angular branches. The leaves are very small and the minute pedicelled flowers are very numerous. The plant is used to regulate hormones and for hepatoprotection during pregnancy because of its immunomodulatory capacity and for the treatment of jaundice, diabetes, dysentery, urogenital diseases, and malaria before pregnancy [92–95]. It is also used to treat gonorrhea and other wart-like genital issues.

Parts used: The whole plant.

Mode of administration: The plant is soaked in alcohol (dry gin) and allowed to stand. The extract is taken orally to treat dysentery and stomach aches both during pregnancy and after delivery (Fig. 9).

2.4.9 *Vitex Agnus-Castus* (Common Name – Sleeping Plant, Indian Gooseberry Plant)

A deciduous hermaphrodite shrub or herb. It is pollinated by Insects and grows well in sandy and loamy soils that are well-drained even in nutritionally poor ones. Suitable pH: acid, neutral, and basic (alkaline) soils. It does not grow well in the shade. The plant is used mainly to manage and treat uterine bleeding disorders and mastodynia [96]. It is also used to improve sexual dysfunction in women undergoing menopause [97]. The plant helps with stress during pregnancy by reducing prolactin and has a hormone-stabilizing effect on prepregnant women.

Parts used: Leaves and stems.

Fig. 9 *Phyllanthus amarus* leaves. (Source: Ghosh et al. [92])

Mode of administration: The leaves and stems are soaked in dry gin and the extract is taken orally to treat premenstrual syndrome and menstrual disorder. It increases menstrual flow (Fig. 10).

2.4.10 *Portulaca Oleracea* (Common Name – Purslane Plant)

An annual or perennial prostrate succulent herb. Stem may spread on the ground or be erect. They are smooth and fleshy, more or less reddish, and could reach 40 cm. It produces mucilage in high amounts that enhance the flexibility of female reproductive organs. The plant has antiaging effects on female genitalia as well as numerous antioxidants and antiatherogenic activities. The plant is also used to fight infections and complications during and after childbirth [62].

Parts used: Leaf and stem extract.

Mode of administration: Extract is taken to improve women's fertility and libido (Fig. 11).

2.4.11 *Afrormosia Laxiflora* (Common Name – Aformosia, African Teak)

A small to medium-sized straight tree bearing crooked, drooping branches forming a disheveled crown. It is common in woodland savanna and fringing to dry dense

Fig. 10 Mature *Vitex agnus-castus* with flowers

Fig. 11 *Portulaca oleracea* leaves and flowers. (Source: SEINet Portal Network [98])

Fig. 12 *Afromosia laxiflora* leaves and flowers. (Source: Green Institute [101])

forests. It is used to boost sexual appetite and performance, cure venereal diseases, and stimulate higher milk production [99, 100].

Parts used: Leaves.

Mode of administration: Leaves are soaked and used as a laxative and stomach cleanser in preparation for pregnancy (Fig. 12).

2.4.12 *Agelaea Obliqua* (Common Name – Esura)

Scrabbling shrub with shining leaves. Flowers pure white or tinged yellow, green or pink, fragrant; fruits scarlet, in forest and secondary growth. The plant is taken to support and boost sexual functions [102].

Part used: Leaves.

Mode of administration: Leaves are consumed raw or in processed form due to their aphrodisiac properties and to treat mild vaginal infections (Fig. 13).

2.4.13 *Alstonia Boonei* (Common Name – Stool Wood)

A tree with grayish bark that exudes a bitter-tasting latex. The leaves may be elliptic or oblanceolate in shape. Whorled and angular branches covered with white lenticels. Inflorescence is repeatedly branched in whorl, with flowers in threes. Herbal decoction prepared with the plants are taken to address fever, insomnia, joint and body pains, and diarrhea. It is used to address abdominal pains, pelvic congestions, ovarian cysts, uterine fibroid, menstrual pains, and microbial infections before, during, and after pregnancy [105].

Part used: Leaves.

Fig. 13 Agelaea species. (Source: Willis [103]; Martin and Harvey [104])

Mode of administration: Leaves in combination with alligator pepper and other medicinal plants are used to prepare soup for pregnant women that are believed to allow the fetus to develop well and promote safe delivery (Fig. 14).

2.4.14 *Aneilema Hockii* (Common Name – Aneilema)

Tufted perennial with erect or straggling shoots. Roots are thick and fleshy. Leaves are spirally arranged. The large, bluish flowers readily distinguish this species.

Fig. 14 *Alstonia boonei* leaves and flowers. (Source: Ileke [106])

Capsules are generally longer, less pubescent, and have seeds in capsules that are emarginated and lack a terminal apicule. The plant is taken to increase fertility and fight venereal diseases. It is also used to treat malaria during pregnancy [107].

Part used: Leaf and root extract.

Mode of administration: Leaf and root extract are taken to prevent miscarriage and maintain the health of the mother and fetus (Fig. 15).

2.4.15 *Apium Graveolens* (Common Name – Celery)

Biennial to perennial herb. The leaves are lobed on each side of the central axis and has a row of two or more lobes on each side of the central axis. The leaves are used to increase fertility and balance hormone production. Herbal decoction prepared from the seed is used to stabilize the blood pressure of pregnant women [109]. The plant is also known to have antioxidant properties relevant for addressing oxidative stress issues in pregnant women.

Part used: Leaves and seed extract.

Mode of administration: Herbal extract prepared with *Apium* species to improve reproductive vigor in women. It is also taken to correct any sexual dysfunction in women (Fig. 16).

2.4.16 *Brunfelsia Uniflora* (Common Name Kiss Me Quick)

A medium-sized, evergreen shrub or small tree with diffuse, spreading branches. It usually grows 0.5–3 m tall. The plant is known to have antioxidant properties relevant for addressing oxidative stress issues in pregnant women.

Part used: Leaf.

Fig. 15 *Aneilema hockii.* (Source: Hyde et al. [108])

Mode of administration: The leaf is believed to increase the chances of getting pregnant in young women (Fig. 17).

2.4.17 *Cucumeropsis Mannii* (Common Name – Melon)

A climber with stems that are sparse crisped-hairy. Leaf-blade are broad ovate-cordate or reniform-cordate. Fruits are cylindrical-ellipsoid, and rounded. Seeds ovate in outline, compressed, smooth, and white. The plant is used to protect and maintain a healthy female genital system and to boost fertility [112].

Part used: Seeds.

Mode of administration: Crushed seeds are blended and mixed with other herbal remedies to improve female fertility and conception (Fig. 18).

Fig. 16 *Apium graveolens* leaves. (Source: Dennis et al. [110])

2.4.18 *Euphorbia Deightonii* (Common Name – Ejagham)

A shrub, branching from the base without a distinct trunk, to 6 m high. The plant appears to be always cultivated. It is commonly grown as a hedge-plant, the lowest branches becoming buried in the ground thus providing a thick barrier to the base. The plant contains copious white latex, which is said to be poisonous. It is an irritant in wounds. An herbal remedy prepared with the plant is used to improve endocrine pathways and treat polycystic ovary syndrome [63].

Part used: Succulent stem.

Mode of administration: Chewed and swallowed (Fig. 19).

2.4.19 *Heeria Insignis* (Common Name – Heer Plant)

A branched shrub or small tree. Leaf undersurface is silvery-white and flowers small, and creamy; fruits are glossy and black. Inflorescences of terminal and axillary, much-branched panicles. The leaves are boiled and used in the treatment of viral and microbial infections before and during pregnancy [114]. It contains important secondary metabolites. It is used to prevent and treat malaria before and during pregnancy.

Fig. 17 *Brunfelsia uniflora.* (Source: Makoto [111])

Part used: Leaves.

Mode of administration: The plant is taken to improve lactation after childbirth (Fig. 20).

2.4.20 *Macaranga Barteri* (Common Name – Macaranga, Akan)

An evergreen climbing shrub or a tree. The spiny bole have spreading and spiny branches. It is a dioecious species. Leaves and seed extracts are used to improve fertility, treat stomach ache, and fight venereal diseases like gonorrhea.

Part used: Leaf and seed extracts.

Fig. 18 Opened *Cucumeropsis mannii* fruits. (Source: Morris [113])

Fig. 19 *Euphorbia deightonii*

Mode of administration: Leaf and seed extract are taken as an abortifacient, to treat sexually transmitted infections, and stomach cleanser in preparation to get pregnant (Fig. 21).

Fig. 20 *Heeria insignis.* (Source: Tropical Plants Database [115])

2.4.21 *Penianthus Zenkeri* (Common Name – Ewe)

A dioecious, evergreen shrub or small tree. Leaves are arranged spirally, simple, and entire; with stipules absent. Seed ellipsoid, seedling with epigeal germination.

Part used: Root, stem, and leaf.

Mode of administration: The roots, stem, and leaf extract are used as an aphrodisiac, and branches, bark, and roots are so used. They are also used to treat impotence (Fig. 22).

2.4.22 *Persea Americana* (Common Name – Avocado, Pear)

It is a medium to large evergreen tree (although some varieties lose their leaves before flowering starts). The tree canopy ranges from low, dense, and symmetrical to upright and asymmetrical. Leaves are variable in shape (elliptic, oval, lanceolate). They are often pubescent and reddish when young, becoming smooth, leathery, and dark green when mature. Flowers are yellowish green, and 1–1.3 cm in diameter. The plant seed is used for hormonal management and to improve lactation [117, 118].

Part used: Leaf and seed extract.

Mode of administration: Extract from the leaf and seed are taken to improve female reproductive hormone and fertility control as well as improve maternal health (Fig. 23).

2.4.23 *Azadirachta Indica* (Common Name – Neem, Dongoyaro)

A fast-growing evergreen tree with wide and spreading branches. The leaves are opposite and pinnate with missing terminal leaflets. Petioles are mostly short with

Fig. 21 *Macaranga barteri* leaves. (Source: Willis [103]; Martin and Harvey [104])

Fig. 22 *Penianthus zenkeri* leaves and fruits. (Source: Davidson and Christoph [116])

Fig. 23 *Persea americana* leaves and fruits. (Source: Krist [119])

axillary panicle drooping flowers. The fruit endocarp contains 1–3 seeds with a brown coat. The plant is used to manage menstrual flow, improve fertility, and treat malaria during pregnancy [120, 121].

Parts used: Leaves and flowers.

Mode of administration: A decoction of the leaves is taken orally to treat malaria during pregnancy (Fig. 24).

2.4.24 *Carica Papaya* (Common Name – Pawpaw, Uhoro)

It is a tree with a stem that yields copious white latex. It has a weak, soft wooden stem crowned by a terminal cluster of large edible fruits. It is used to boost sexual performance and fertility in women through hormonal balancing and increase in estrogen production.

Parts used: Seeds and Leaves.

Mode of administration: The seeds are used to cause abortion in pregnant women, especially young girls. The leaves are used to treat malaria during pregnancy as a prenatal and postnatal measure (Fig. 25).

3 Conclusion

Though traditional reproductive health service is considered affordable and accessible, the younger generation is more interested in modern medicine, which is characteristically more expensive and less available in certain parts of Benin and Warri cities. The issue is driving the decline and neglect in the practice and resources used

Fig. 24 Azadirachta indica leaves and flowers

Fig. 25 *Carica papaya*

for female reproductive health care, respectively. This is further compounded by the process of urbanization and Western culture, which adds an extra layer to the complex and multidimensionality of female reproductive dysfunction. The threats to this indigenous practice and knowledge system require an urgent revitalization strategy to protect indigenous medical knowledge. Also, only little scientific evidence exists to prove the efficacy of the remedies and plant species employed to treat or manage reproductive disorders. Addressing these issues could lead to the confirmation of their efficacy and the discovery and development of new drugs for modern medicine. Moreover, the medicinal plants documented in this study are considered invaluable for addressing female reproduction dysfunction through traditional approaches and need conservation attention. Their conservation will help preserve the heritage and plant diversity.

S. C. Izah et al. (eds.), *Herbal Medicine Phytochemistry*, Reference Series in Phytochemistry, https://doi.org/10.1007/978-3-031-43199-9_16

Abstract

Traditional plants are the most promising source of phytochemicals for creating herbal medicines. Numerous biosynthetic metabolic networks are important in the biogenesis of phytochemicals and their accumulation in plants under the strong influence of environmental factors. Primary and secondary metabolites generated from plants, or phytochemicals, have great promise as chemotherapeutics for preventing or treating potential public health problems. Pharmaceutical enterprises prepare plant-derived phytochemicals into herbal medicines using various conventional methods while considering the properties of the phytochemicals. These conventional methods of producing phytochemicals as herbal medicines have several advantages and drawbacks. Additionally, the pharmaceutical industry has been forced by drug resistance and population growth to speed up the development and processing of phytochemicals from plants used as herbal medicines to address today's human health problems. Functionalization of plant metabolic networks and its regulatory bioparts has proposed a paradigm change for phytochemicals production in model microbial platforms. Based on this existing situation, the first part of the current summary provides an overview of several plant-derived phytochemicals, their medicinal properties, the biosynthetic network in plants, and conventional methods for processing them. The development of herbal medicines as a sustainable route forward is the subject of the second half, which is centered on modern omics, systems metabolic engineering, and synthetic biology techniques to improve phytochemical synthesis using plant bioparticulates inside microbial platforms.

Keywords

Phytochemicals · Herbal medicine · Plant extracts · Environmental stress factors · System metabolic engineering · Synthetic biology · Sustainable microbial cell factory

Abbreviations

AD	Alzheimer's disease
ADME/T	Absorption, distribution, metabolism, excretion, and toxicity
ASFV	Asian swine flu virus
ATHB	*Arabidopsis thaliana* Homeobox-leucine zipper protein
BAAV	Bovine adeno-associated virus
BC	Breast cancer
CoA	Coenzyme A

CT	Condensed tannins
DMAPP	Dimethylallyl diphosphate
DNA	Deoxy ribonucleic acid
DPPH	2,2-diphenylpicrylhydrazyl
DXP	1-deoxy-d-xylolose-5-phosphate
EC	Esophageal carcinoma
Eca109	Esophageal cancer cell line 109
EGCG	(2)-epigallocatechin-3-gallate
EOs	Essential oils
FA	Ferulic acid
FeLV	Feline leukemia virus
FPP	Furanosyl pyrophosphate
GMOs	Genetically modified organisms
GPP	Geranyl diphosphate
HBV	Hepatitis B virus
HCC	Hepatocellular carcinoma
HCT-15	Human colon cancer type 15
HCV	Hepatitis C virus
HeLa	Henrietta Lacks cell line
HGC	Human gastric carcinoma
HIV	Human immunodeficiency virus
HSPs	Heat shock proteins
HSV	Herpes simplex virus
HT	Human colorectal adenocarcinoma type
IC50	Half-maximal inhibitory concentration
IL	Inerleukine
IMF	Intramuscular fat
IPP	Isopentenyl diphosphate
IRES	Internal ribosome entry site
KYSE30	Human Asian squamous cell carcinoma 30
LTL	Longissimus thoracis et lumborum
MEP	Methylerythritol phosphate
MH7A	TNF-α-stimulated synovial fibroblasts
MICs	Minimal inhibitory concentrations
miRs	Micro Ribonucleic acids
MMP-9	Matrix Metalloproteinase-9
MVA	Mevalonic acid
Nfe2l2	Nuclear factor erythroid 2-related factor 2
NS	Nuclear signaling
OVCAR	Ovarian cancer
PAL	Phenylalanine ammonia lyase
Pcs	Platelet concentrates
PD	Parkinson's disease
Ppargc1a	Peroxisome proliferative activated receptor, gamma, coactivator 1 alpha

PPC	Purple prairie clover
PPT	Podo phyllo toxin
pso	Postsymptom onset
PTHR1	Parathyroid hormone/parathyroid hormone-related protein receptor 1
RA therapy	Rheumatoid Arthritic
RdRp	RNA-dependent RNA polymerase
RLV	Rauscher murine leukemia virus
RNA	Ribonucleic acid
ROS	Reactive oxygen species
RT	Reverse transcriptase
Saos2	Sarcoma osteogenic2
SGC	Sarcoma gastric cercinoma
SKOV3	Epithelial human ovarian carcinoma 3
SPL	Squamosa promoter binding protein-like
StAR genes	STAR steroidogenic acute regulatory genes
T2DM	Type 2 diabetic mellitus
TB	Tuberculosis
TNF	Tumor necrotic factor
Topo II	Topoisomerase II
TPS	Terpenoids
U2OS Line	Human Bone Osteosarcoma Epithelial Cells
UV	Ultraviolet
WHO	World Health Organization

1 Introduction

Plants have long been a crucial source for developing novel medications [1]. Numerous phytocompounds found in them aid in treating and preventing various ailments. Herbal medicine uses a variety of medicinal plants, herbs, or their parts to treat illnesses while boosting overall health and the recovery of disorders [2]. Herbal medicines are the primeval form of healthcare known to us. Over time, a growing trend in the development of herbal medicines has been observed. From different studies, we have seen about 70–85% of the rural population, if we exclude the western countries of the world, have used traditional medicine as their only healthcare system and still continue to do so. The reason lies not only in the poverty of the region to buy expensive drugs but also that they are more culturally acceptable and have continued this practice since ancient era [3]. Plants have the ability to secrete secondary metabolites. Phytochemicals present in herbal plants are bioactive chemicals that provide us certain desirable health benefits. These phytochemicals also have some commercial importance like its usage as a pharmacological tool to study various biochemical processes, tannins acting as astringent, and quinones being used as antimicrobial agent. As it relates to immunity, certain phytochemicals strengthen the immune system, preventing the body from being harmed by illnesses [4]. There is also the notion that every ailment has a suitable treatment method built into it by nature. The invention of novel herbal medications, which in many aspects have proven to be superior to conventional pharmaceuticals [5], has been facilitated by the growing research and improvements in the extraction and characterization of phytochemicals.

According to many recent World Health Organization (WHO) investigations, these phytochemicals are present in more than 75% of persons who only rely on herbal medications. The phytochemicals saponins, tannins, anthraquinones, terpenoids, and many others are all found in herbal plants. It has been established that each of these phytochemicals has biomedical applications that may be further developed into herbal medications to treat diseases more effectively [6]. Herbal medicines are cost effective and have been proved advantageous over allopathic medicines which have adverse side effects and toxicity in many approaches. These have over a long period of time resulted in tremendous growth for producers of herbal medicines. People without prescriptions have also been shown to utilize more herbal medications [7]. Leaves, stems, barks, seeds, roots, and extracts from these are used in herbal medicine. Though herbal medicines are not able to cure rapid sickness and possess complexity of standardization, yet they have been proved beneficial in many ways like being cost-effective, recyclable, and with comparatively less side effects as they have been derived from natural source – plants – providing more protection with enhanced tolerance and much more. Through decades, these medicines have been tested and widely used to cure various fatal diseases like cardiovascular diseases, cancer, type 2 diabetes, and a lot to be added to the list [8]. Researchers have further found that phytochemicals possess antioxidant abilities. According to studies, the overproduction of oxidants in the human body causes serious damage to big macromolecules like DNA, proteins, and lipids. This pathogenesis of fatal diseases like cancer, cardiovascular disorders, and many others is due to this damage. The phytochemicals' antioxidant property has been extremely helpful in the treatment and prevention of chronic diseases. Researchers have revealed that many of the antioxidant phytochemicals have been found to possess anti-inflammatory actions [9, 10]. They reduce inflammation by inhibition of prostaglandin production and nuclear factor activity. They also inhibit enzyme production and increase the production cytokines which adds on a better defense mechanism to the human body. These antioxidant phytochemicals other than possessing anti-inflammatory actions and strong oxidant also have free radical scavenging activities which further forms the basis of other bioactivities and provides several other health benefits. Other than the chronic diseases, obesity is rising in alarming rates all around the world. Not only obesity comes with other health-degrading factors like respiratory problems, infertility, sleeping problems, and osteoarthritis, but also it is becoming a major health burden with social and economic costs. Phytochemicals present in herbal medicine have been able to cure obesity eradicating other health issues coming with it [11].

Phytochemicals also provide us a lot of other health benefits when consumed as they consist essential nutrients like vitamins, minerals, and proteins for optimal health. As all products come with pros and cons, here too with herbal medicines a few things are to be kept in mind. At times, all herbal medicines are considered safe as they do not use any synthetic products and are derived from natural source, but sometimes they also produce certain side effects and allergic reactions [12]. They may also result in nauseousness, vomiting, diarrhea, exhaustion, seizures, and other symptoms. This frequently happens as a result of self-dosing, when the patient does not fully understand the medication or is unaware of any potential allergens in the medication, leading to health problems later. Because herbal medicines may be purchased without a prescription, many individuals do so without learning everything there is to know about them. Despite this, herbal medicines are an excellent alternative to costly medications. Despite these obstacles, herbal medications have been shown effective through years of human research. Some medications have been combined with other herbs to successfully balance the side effects, making them safe for human use with the advantage of having no negative side effects. However, some medications have been withdrawn owing to toxicity. In Asian nations, herbal medications are often employed, and they have been effectively used for decades to synchronize immune system activities. This category includes at least 35 plants, and other herbs are utilized to create pharmacological medicines. As a result, research on herbal treatments has increased throughout the years. An effort has been made to highlight numerous phytochemical developments in the evolution of herbal therapy in this issue [13].

2 Outlines on Phytochemicals from Plants as Potent Herbal Medicine

Phytochemicals are called "Secondary metabolites" as they are produced due to the reaction of primary metabolites as amino acid, sugars, etc. Several phytochemicals that are derived from plants and are potent herbal medicines have been classified as follows:

2.1 Terpenoids

With five carbon isoprene units that can be combined in various ways, terpenoids make up the biggest class of secondary metabolites. A subgroup of terpenes called terpenoids has undergone alteration, moving or removing various functional groups and oxidized methyl groups at various locations. They are further divided into monoterpenes and have ten carbon atoms and two isoprene units; sesquieterpenes have three isoprene units; diterpenes have four; sesterpenes have five; and triterpenes have six. Terpenoids contained in herbal treatments are used to make anticancer medications, which are used to treat terminal conditions like cancer. These are additionally used in the development of antimalarial drugs [14].

2.2 Polyphenols as Herbal Medicine

According to studies, more than 8000 polyphenolic compounds, which are derived from the amino acid phenylalanine or its closely related component shikimic acid, are found in various plants. These molecules generally exist in conjugated form, where hydroxyl groups are attached to one or more sugar residues. These are further divided into phenolic acid, flavonoids, lignans, and stilbenes, which also have antifungal properties and two phenyl moieties connected by a two-carbon methylene bridge and two aromatic rings connected by three carbon atoms. Polyphenols aid in the treatment of chronic illnesses, such as reducing the prevalence of coronary heart disease. Additionally, they boost plasma antioxidant capabilities, which lower the chance of developing numerous degenerative illnesses [15].

2.3 Phytosterols as Herbal Medicine

More than 300 families of phytosterols have been found by researchers, some of which include beta-sitosterol, beta-sitostanol, campestanol, campesterol, and stigmasterol. In addition to lowering the high risk of cardiac arrest, phytosterols are particularly effective at treating excessive cholesterol. Due to their structural resemblance to cholesterol, they compete with cholesterol for the digestive system's attention. Now that sterol is digested in place of cholesterol in our bodies, part of the cholesterol is excreted as waste. Phytosterols are also an excellent treatment for diabetes and obesity [16, 17].

2.4 Alkaloids as Herbal Medicine

Alkaloids are composed of at least one nitrogen atom and are a form of amine, and their structures are incredibly varied. The different subparts of alkaloids include morphine, quinine, nicotine, ephidrine, and strychnine. These phytochemicals offer a number of therapeutic benefits, including the ability to cure arythmias and to lessen uterine hemorrhaging, hay fever, and bronchial asthma [18].

3 Therapeutics Features Plant-Derived Phytochemicals as Herbal Medicine

3.1 Saponins

Saponin has anti-inflammatory qualities, making it a viable RA therapy. A component of *Aralia taibaiensis* root extract called saponin can suppress the migration and proliferation of synoviocytes, specifically MH7A cells (IL-1, IL-6, IL-8, and TNF), and can lower the production of proinflammatory cytokines in vitro. A triterpenoid saponin called Tubeimosid I that was isolated from *Bolbotemma paniculatum* has the capacity to reduce MMP-9 expression in vitro. Recent evidence suggests that a variety of saponins, including those found in soy, ginseng, dioscins, and avicins, have played a variety of roles in the treatment of tumors. Few antitumorigenic medication combinations with saponins result in synergistic effects with possible growth suppression [19]. Angiopoietic and endothelial tyrosine kinase receptor expression can be induced by saponins from *Rhizoma dioscoreae nipponicae* [20].

3.2 Phenols

Large amounts of ferulic acid (FA), a naturally occurring phenolic component, are found in herbal plants. Numerous therapeutic advantages of FA have been documented, including ones that are anti-inflammatory, antioxidant, anticancer, and antidiabetic. It is important to remember that FA has prooxidant and antioxidant properties in addition to a range of antibacterial activities against all infections. In addition to preventing arsenic-induced toxicity in the male genital system, FA has a protective effect through reducing oxidative stress and testicular damage. Regulating the expression of the Nfe2l2, Ppargc1a, and StAR genes also increased the quality of the sperm [21]. The rhizome of the turmeric plant yields curcumin (*Curcuma longa*), one of the most important bioactive polyphenolic compounds. This chemical has well-documented anti-inflammatory, antioxidant, and anticancer properties. Researchers have discovered that curcumin can protect against fatal diseases in animal models of ailments like Alzheimer's disease (AD), Parkinson's disease (PD), depression, multiple sclerosis, ischemic stroke, etc. Curcumin's role in preventing stomach cancer has been documented in numerous studies. When curcumin was given orally to animal models of gastric cancer, carcinogenesis and tumor growth were significantly reduced. The anticancer effects of curcumin were demonstrated in HeLa cervical cancer cells. The results show that curcumin's IC50 value of 34.23 M/ml was effective in slowing the development of cancer cells. Curcumin usage inhibits cervical cancer cell invasion, proliferation, and enhanced cell death [22]. Salvianic acid B, a significant water-soluble polyphenolic acid, is produced by Radix Salviae Miltiorrhizae, a traditional herbal remedy that has been utilized as an antioxidant in Chinese medicine for thousands of years. There are numerous medicinal plants that contain gallic acid, including *Barringtonia racemosa*, *Cornus officinalis*, *Cassia auriculata*, *Polygonum aviculare*, *Punica granatum*, *Rheum officinale*, *Sanguisorba officinalis*, *Terminalia chebula*, and *S. chinensis*, as well as dietary spices like thyme and clove. According to certain reports, gallic acid has an inhibitory effect on bacterial dihydrofolate reductase and an excitation effect on topoisomerase IV-mediated DNA breakage in various bacteria. Alkyl gallates can also breach the bacterial cell membrane and obstruct cellular respiration and the electron transport chain [23].

3.3 Flavonoids as Herbal Medicine

Apples, grapes, red raspberries, shallots, cabbage, vegetables, and almonds are just a few examples of foods that contain quercetin, a bioactive flavonoid component. The antioxidant and anticancer effects of quercetin are well-known, as well as its ability to prevent metastasis and trigger apoptosis. Because of its biological and pharmacological effects on disorders such as atopic dermatitis, renal fibrosis, myocarditis, and neurodegenerative diseases, previous research have suggested that quercetin may decrease the advancement of degenerative diseases. It has also been applied to the treatment of cardiovascular disease and cancer. Li et al. [24] revealed quercetin's anticancer efficacy on cell growth and inhibition rates of U2OS and Saos2 human metastatic osteosarcoma cells through lowering PTHR1 activity. Myricetin is a bioactive flavonoid that is present in a wide range of edible plants, such as grapes, oranges, berries, and teas. Myricetin exhibits significant biological properties such as anti-inflammatory, antioxidant, and anticancer action. Numerous cancer cell lines, including those from the stomach (HGC-27 and SGC-7901), esophagus (EC9706 and KYSE30), ovarian (OVCAR-3, A2780/CP70, and SKOV3), colon (HCT-15, and HT-29), and cervix (HeLa), have verified the function of myricetin in preventing the proliferation of cancer cells and encouraging apoptosis. It also inhibited glucosidase and amylase, which helped prevent type 2 diabetic mellitus (T2DM) [25]. Luteolin, an active flavonoid component present in a range of plants, including broccoli, celery, pepper, and thyme, activates p53 and induces autophagy in hepatocellular carcinoma (HCC) cells. Numerous pharmacological and biological properties of luteolin have been shown, including anti-inflammatory, anticancer, antioxidant, and antidiabetic actions for the treatment of diabetic nephropathy. Eca109 esophageal cancer cells undergo apoptosis as a result of luteolin [26]. The results show that in esophageal cancer Eca109 cells, luteolin, a natural chemical, promotes caspase3, caspase9 mRNA, and protein expressions during cell death [27].

3.4 Tannins as Herbal Medication

Recently, many investigations have been carried out to determine the pertinent antioxidant activity of tannins. Much attention has been given to the antioxidant capabilities of tannins, which include protecting against osteoporosis, cancer, and cardiovascular disease. From the leaves of *F. altissima*, condensed tannins (CT) have also shown to have better antioxidant activity. According to a study, tannins at doses of 0.13%, 2.25%, and 0.45% significantly increased feed conversion rates, decreased cecum levels of ammonia, isobutyric, and isovaleric acid, decreased the depth of ileal crypts, and decreased intestinal bacterial proteolysis [28]. The mechanism of tannins was investigated by researchers using a bacteriostatic model. *E. coli* O157:H7 strain 3081 was tested on condensed tannins (CT) from purple prairie clover (*Dalea purpurea* Vent; PPC), which have anti-*E. coli* O157:H7 action. After 24 h, optical density at 600 nm was measured to assess bacterial growth. CT prolonged the lag period and slowed *E. coli* O157: development. The ability of a hydrolyzable tannin derived from chestnut to control *Clostridium perfringens* growth in the gut has been studied [29].

According to certain studies, tannins can shield the body from viruses like norovirus, bovine adeno-associated virus (BAAV), and HIV. When tannins' inhibitory effects on HIV-1 were evaluated, the results showed that tannins prevented the development of syncytia, lytic effects, the synthesis of the viral p24 antigen, and HIV-1 reverse transcriptase (RT) enzyme activity. Some plant extracts exhibit substantial inhibition of HIV-I integrase activity, according to results of a different investigation on this subject. Results showed that (2)-epigallocatechin-3-gallate (EGCG), an active component of green tea, directly interacted with the hepatitis C virus (HCV) in vitro and prevented the virus from adhering to the cell surface [29]. Condensed tannins' ability to kill parasitic adults and free-living larvae provided evidence for their potential use in the management of various stages of parasite development. In conclusion, the direct mechanisms include restricting larval development to lessen the establishment of infected third-stage larvae in the host and reducing spawning to inhibit the motion performance of the parasite [28, 29]. The indirect mechanisms include boosting the human immune system and infection resistance.

3.5 Alkaloids and Its Medicinal Impacts

Alkaloids are well-known for their ability to relax muscles. One such example is D-tubocurarine, which has antiparasitic properties because it can impede the acetycholine receptor sites that allow muscle relaxation at neuromuscular junctions. Using DPPH and metal chelating tests, it was discovered that the linearilobin, linearilin, and lycotonine browniine norditerpene alkaloids, which were isolated from the roots of *Delphinium linearilobum*, have antioxidant activity. The alkaloid 6-methoxydihydrosanguinarine was shown by Yin et al. [29] to be capable of controlling the synthesis of reactive oxygen species (ROS) and inducing apoptosis. Sanguilutine and chelilutine, two quaternary benzo[c] phenanthridine alkaloids, have comparable types of action processes. The cytokine TNF is widely acknowledged to be crucial for managing inflammation. Conophylline is said to prevent TNF-induced NF-B activation by lowering the expression of TNF-receptors on the cell surface. The Amaryllidaceae alkaloids lycorine and lycoricidinol either blocked protein synthesis or altered how cysteine/methionine was absorbed into macrophages, hence lowering TNF-production. Wirasathien et al. have demonstrated the antituberculosis, antimalarial, and cytotoxic effects of aporphine alkaloids from the aerial part of *Pseuduvaria setosa* on *Mycobacterium tuberculosis*, breast cancer (BC), and small cell lung cancer (NCIH187) cell lines. The antiviral activities of Eudistomin, a novel oxathiazepine ring containing alkaloids isolated from *Eudistoma olivaceum* against RNA viruses like *Coxsachie A*-21 and equine rhinovirus and against DNA viruses like HSV-1, HSV2, and Vaccinia virus, have been mentioned by Gul and Hamann in their review on indole alkaloids. While [30] established the anti-HIV action of Coscinamide alkaloids derived from *Coscinoderma* sp., [31] demonstrated that Dragmacidin alkaloids obtained from *Spongosorites* sp. were reported to suppress in vitro replication of feline leukemia virus (FeLV).

3.6 Essential Oils (EOs) as Herbal Medicine

Lavender oil has MICs that range from 0.16 to 11.90. Numerous microorganisms, including the majority of bacteria, yeasts, and filamentous fungus, are susceptible to the antibacterial effects of lavender oil. Additionally, it exhibits antisepsis action. Additionally, EO aids in the treatment of pain, profound anxiety, sleep disorders, and stress. On *Aspergillus*, *Candida*, and *Dermatophyte* strains, extract from *Lavandula luisieri* shows a fungicidal action. According to recent investigations, a number of the constituents of lavender essential oil have been revealed to have anticancer and antimutagenic properties. *Staphylococcus aureus*, *Staphylococcus pyogenes*, and *Haemophilus influenza* are just a few of the gram-positive and gram-negative microorganisms that are resistant to eucalyptus oil's powerful cytotoxic and antibacterial effects. Eucalyptus oil can be used as an adjuvant in immunosuppression and for the treatment of tumors. Peppermint oil, which has fungistatic and fungicidal activities with minimal inhibitory concentrations (MICs) of 0.5–8 ul/ml, inhibits the development of *Staphylococci*. *Candida albicans* cannot produce biofilms when given a dose of 2 ul/ml of PO. Oral infections and oral biofilm are strongly inhibited by Melaleuca gel, which includes an extraction from the *Melaleuca alternifolia* plant [32]. Three *Candida* species – *C. albicans, C. glabrata*, and *C. tropicalic* – are susceptible to the therapeutic effects of lemon oil. Dentistry makes extensive use of the eugenol-containing clove oil's therapeutic capabilities. It also prevents *C. albicans* from forming germ tubes. Additionally, it exhibits significant inhibitory effect against *Staphylococcus* spp. that are multidrug resistant. The plant from which cinnamon oil is extracted, *Cinnamomum zeylanicum*, possesses qualities that include antibacterial, fungicidal, antimutagenic, antioxidant, and antiparasitic [32].

4 Biosynthetic Networks for Phytochemicals Biogenesis in Plants

Over time, there has been a lot of interest in the role of miRNAs in regulating plant-secondary metabolites and metabolic processes. This work improves our knowledge of the functions of miRNAs in the control of miRNA-targeted genes and the manufacture of essential oils, terpenoids, alkaloids, and saponins. The class of phenyl-propanoids includes the majority of secondary metabolites found in plants. These compounds are derived from the aromatic amino acid phenylalanine. Flavonoids, phenolic acids, stilbenes, coumarins, and monolignols make up the majority of what they contain. The secondary metabolites indicate its important roles, and it is abundant in the majority of plant kingdoms. It is interesting to note that active miR-8154 and miR-5298b also increase the phenyl-propanoid content, whereas the target genes for the miRNAs (miR-9662, miR-894, miR-172, and miR-166) are essential for controlling the metabolic biosynthetic process of phenyl-propanoid saponin in plants [33].

The cytosolic mevalonic acid (MVA) system and the plastidial methylerythritol phosphate (MEP) pathway are the two separate processes that produce terpenoids. In contrast to abiotic stress, biotic stress results in a significant production of terpenoid compounds. According to transcriptional study, the terpenoid backbone biosynthesis in the leaves of *Ananas comosus* var. *Bracteatus* is carried out by roughly 43 identified unigenes. Terpene production is also regulated by the *Ferula gummosis* miRNAs miR-2919, miR-5251, miR-838, miR-5021, and miR-5658. However, it is hypothesized that miR-5021 and miR-5658 regulate the *Arabidopsis* transcription factors SPL7, SPL11, and ATHB13, which are known to be involved in terpenoid production.

Indole, piperidine, tropane, purine, pyrrolizidine, imidazole, quinolizidine, isoquinoline, and pyrrolidine are among the substances that make up alkaloids. These substances are produced by the metabolism of many alkaloids. Many miRNAs, including pso-miR-13, pso-miR-2161, and pso-miR-408, were found to regulate the alkaloid synthesis pathway in the Opium poppy plant (species of flowering plant in the *Papaveraceae* family), according to research published in 2014. The pso-miRNA-2161 functions as an intermediary molecule in the synthesis of benzylisoquinoline alkaloids and is regulated by the mRNAs for the enzymes S-adenosyl-L-methionine, 30-hydroxy-*N*-methylcoclaurine, and 40-O methyltransferase [34].

Essential oils are important secondary metabolites of plants that have been used in a wide range of ethnobotanical medicines since the beginning of time. Essential oils are created via two intricate natural biochemical processes that involve several enzyme activities. Isopentenyl diphosphate (IPP) and its isomer dimethylallyl diphosphate (DMAPP), the universal precursors of essential oil biosynthesis, are produced by either the cytosolic enzymatic MVA (mevalonic acid), also known as the 2-C-methylerythritol-4-phosphate pathway or the plastidic and enzymatic 1-deoxy-d-xylolose-5-phosphate (DXP) pathway. To create prenyl-diphosphates, which act as substrates for either geranyl diphosphate (GPP; C10) or fernesyl diphosphate in the specific plant cell component (FPP; C15), prenyl diphosphate synthases further combine isopentenyl diphosphate (IPP) and dimethylallyl diphosphate (DMAPP). Terpene synthases are a vast category of enzymes that produce essential oils, which are the ultimate terpenoid molecules (TPS) [35, 36].

5 Environmental Factors' Effects on the Production of Phytochemicals in Plants

Weak knowledge exists regarding how the environment affects the quantity of secondary metabolites found in fruits and vegetables. Although descriptions of metabolic pathways are improving, it is still unclear and difficult to quantify how environmental factors affect such pathways. With the exception of light quality, the main hypothesis concerning how environmental conditions affect the production and accumulation of carotenoids and polyphenolic chemicals in fruits and vegetables will be reviewed in this talk. First, there is a connection between the primary and secondary metabolisms. The biosynthesis of carotenoids and polyphenolic compounds is influenced by the carbon status. Second, the importance of secondary metabolites in helping plants adapt to their environment is now generally acknowledged. Reactive oxygen species (ROS), specifically, may be involved in how biotic and abiotic constraints affect the synthesis of carotenoids, according to substantial evidence.

In order to help farmers in developed and developing countries produce fruits and vegetables with higher phytochemical concentrations without using genetically modified organisms (GMOs), all of these hypotheses and modeling prospects are presented and discussed from a controlling point of view. According to a theory that is being debated, fruits and vegetables grown organically have higher amounts of polyphenols and perhaps carotenoids, which may have health advantages. The importance of secondary metabolites in plants' ability to adapt to their environment is now well-known, which brings us to our second point. Reactive oxygen species (ROS) may operate as a mediator between biotic and abiotic limitations and the synthesis of carotenoids, according to data, which strongly support this theory. All of these concepts and the possibility of modeling are presented and analyzed from a controlling standpoint. It has been hypothesized that fruits and vegetables grown using organic methods contain greater levels of polyphenols and perhaps carotenoids, which in turn contribute to their health advantages [37].

5.1 Secondary Metabolites in Plants as a Function of Light Intensity

A well-known indole alkaloid called camptothecin reacts to environmental stresses, and changes in light irradiation conditions can affect how quickly it accumulates. Overshadowing, for instance, has been shown to cause biochemical alterations in plants, particularly leaves. For instance, *Camptotheca acuminata*'s leaves showed a higher concentration of camptothecin under severe shadowing than the lateral roots did during 100% full sunshine (as compared to 27% full sunlight) [38].

5.2 Bioavailability of Phytochemicals

In vitro and animal studies have demonstrated that several phytochemicals offer a great deal of promise for application in therapeutic settings. When these drugs are employed clinically, however, this is frequently not the case; a lot of them are limited because of their xenobiotic activity (the presence of foreign molecules) before they reach their intended organ or tissue. Phytochemicals frequently encounter difficulties due to their quick metabolism and indigestibility. Additionally, they may be impacted by other phytochemicals included in the consumed material as well as interactions between various plant components [39, 40].

5.3 Biogenesis of Phenolic Compounds

Phenolic compound biogenesis Plant PC molecule architectures often differ greatly from one another. Contrarily, simple phenols have just one aromatic ring, oxy-benzoic and oxyric acids have two rings plus a tri-carbon fragment, flavonoids have two rings, and oxy-coumarins contain benzene and pyrone rings. Simple phenols also have just one aromatic ring. PCs differ in where they are located inside the molecule and have distinct oxy-group numbers. Based on it, there are mono-, di-, and polyphenols. In PCs, the hydrogen of the oxy group may occasionally be replaced by methyl or another functional radical. It was discovered that PCs are produced through the polyketide pathways acetate-malonate and shikimate. Along the shikimate route, phenyl-propanoid substances such as hydroxy-cinnamic acids and coumarins are produced. The major enzyme of the phenylpropanoid pathway, phenylalanine ammonia-lyase (PAL), uses the phenylalanine aromatic amino acid, which is produced by the shikimate route. This activated p-coumarate reacts with malonyl-CoA and the essential enzyme chalconsintase to form chalcones. The latter deaminates aminocinnamic acid, resulting in the production of p-coumarin CoA. Naringenin, a precursor to other flavonoids, is produced as a result of the product's isomerization. The PAL enzyme, which changes phenylalanine from deamination to transcinnamic acid, was initially described in the chapter [41].

Information on the function of the PAL was obtained by examining how the enzyme activity was impacted by biotic and abiotic stressors (light, wound, phytopathogens, and alterations in mineral balance). A de novo link was discovered between the expression of the relevant gene, PCs accumulation, and PAL biosynthesis. Other well-established regulation mechanisms were founded on the feedback principle in transgenic tobacco plants and posttranslational phosphorylation changes of the enzyme. The acetate-malonate route for PC production is common in lichens, fungi, and microorganisms. Through its participation, flowering plants produce flavonoids, with the acetate-malonate route creating one ring and the shikimic pathway creating the phenylpropanoid ring. When the molecules condense, coumarin-CoA and three molecules of malonylCoA result in the formation of a chalcone. The process is catalyzed by chalcon synthase, the main enzyme in the polyphenol flavonoid biosynthesis block. The generated tetraoxychalcon is converted into the flavanone naringenin, which begins nearly all other families of flavonoids with the exception of chalcones and dihydrochalcones. Flavonoids, which are derivatives of 3-phenylchroman, are also capable of producing a large number of isoflavonoids, which are derivatives of 2-phenylchroman. It was discovered that the intermediates and final products of the flavonoid pathway accumulated where they were synthesized. In spite of the tremendous structural variety of phenolic compounds, there are only two primary biosynthetic routes for them: shikimic and acetate-malonate. In higher plants, the shikimic pathway is a crucial part of cellular metabolism [41].

5.4 Time-Scale Variability

Most frequently, each population of plants has a unique and wild type secondary metabolite profile. Plant secondary metabolite profiles and contents can be linked to a number of variables, including the season, hour of the day, tissue age, and temperature because this particular attribute is time-dependent. Sesquiterpene lactones and flavonoids accumulate in the *Vernonieae* species (*Asteraceae*), which are Indigenous to central Brazil. *Lychnophora* spp. and *Eremanthus* spp. are two examples of plants from this Compositae that display a range of metabolite profiles and bioactivity. The volatile terpenes from *Virola surinamensis* also accumulate in an unusual manner; they modify their rates of accumulation in response to the seasonal patterns of the Amazon jungle. For instance, evening monoterpene levels are lower during a rainy winter. Seasonal patterns of secondary metabolite synthesis in plants can be explained in terms of UV radiation, humidity, and high temperatures. For instance, the elder leaves of *Medicago sativa* accumulate summer cuts, medicagenic acid, and saponins [42].

6 Traditional Approaches for Production and Processing of Plant-Derived Phytochemicals

Podophyllotoxin Aryltetralin Lignin

Given that *Podophyllum peltatum*, *P. hexandrum*, *Linum reader*, and *L. narbonese* develop themselves in the rhizomes and roots of some plants, it is possible that these substances contain aryltetralins. The inventory of PPT from natural sources have been constrained as a result of overharvesting and environmental risks. In addition to being an effective anticancer agent by itself, it also acts as a precursor for the creation of a number of semisynthetic derivatives, including etoposide and teniposide, both of which have significant commercial value because of their effectiveness against acute leukemia, testicular/small cell lung cancer, Hodgkin and non-Hodgkin's carcinoma, and, respectively, acute leukemia and non-Hodgkin's carcinoma. PPT functions primarily by inhibiting Topo II, which blocks protein tyrosine kinase and causes DNA damage and cell death by stopping the cell cycle in the G2 phase. The organic combination of this emulsion is sensitive because of the complex chemical makeup and great cost-effectiveness [43].

6.1 The Health Benefits of Phytochemicals Derived from *Catharanthus roseus:* Possibility of Use as an Anticancer Drug

Vinblastine, vincristine, vindoline, vindolidine, vindolicine, vindolinine, and vindogentianine are a few of the anticancer alkaloids found in *C. roseus*. They alter the dynamics of microtubules to cease cell division and start apoptosis. Vinblastine and vincristine were the first of these plant-derived anticancer medications to be used in clinical settings. Hodgkin's disease, lymphosarcoma, choriocarcinoma, neuroblastoma, breast carcinoma, and various organs in acute and chronic leukemia have all been treated with vinblastine sulfate. Vincristine sulfate, an oxidized form of vinblastine, is effective in treating reticulum cell sarcoma, lymphocytic leukemia, Hodgkin's disease, Wilkins' tumor, and acute leukemia (in children). It also stops mitosis during the metaphase.

Other indole alkaloids from *C. roseus* have been demonstrated to be sensitive to a variety of cancer cell lines. It was reported that the human promyelocytic leukemia HL-60 cell line was repressed by catharoseumine, a novel monoterpenoid indole alkaloid that was isolated from the entire plant of *C. roseus*. The IC50 value for this alkaloid is 6.28 M, making it a potent inhibitor. In addition, three newly isolated dimeric indole alkaloids – 14′,15′-didehydrocyclovinblastine, 17-deacetoxycyclovinblastine, and 17-deacetoxyvinamidine – and five previously identified substances – vinamidine, leurosine, catharine, cycloleurosine, and leurosidine – exhibited an IC50 range of 0.73–10.67 M in vitro inhibition of cell viability against the human breast. It is significant that the recently identified bisindole alkaloid cathachunine from *C. roseus* showed antitumor effects on human leukemia cells but significantly less cytotoxicity than on healthy human endothelium cells, demonstrating that it only reduced activity on leukemia cells. Along with examining each individual *C. roseus* alkaloid's anticancer properties, the effects of the crude extract of *C. roseus* as a whole were investigated on a number of cancer cell lines. Recent investigations have demonstrated the *C. roseus* root and stem extract's strong in vitro cytotoxic activity against a number of cancer cell lines. Similar to this, Fernández-Pérez et al.'s work showed that the potent anticancer activity of the indole alkaloid-enriched extract from *C. roseus* cell cultures was not a result of a single molecule acting alone but rather a result of the combined action of multiple bioactive substances. These findings demonstrated how the bioactive elements in *C. roseus*, which have already been discovered in other plant materials and are being explored as a therapy option, cooperate to positively combat cancer cells. By increasing bioavailability, lowering metabolism and excretion, complementing modes of action, reversing resistance, and mitigating adverse effects, substances with little to no activity compared to the primary active components assist the active component in reaching the target. This support makes this phenomenon conceivable [44].

6.2 Phytochemicals and Therapeutic Plants That Fight Viruses

Many plants have been utilized in medicine from the beginning of time because of their powerful healing abilities. Many of these herbs have been used in conventional medicine to treat viral illnesses. The main findings regarding plant extracts' antiviral properties are compiled in Table 1. Only a few of the listed extracts underwent in vivo testing; other extracts were examined in cell culture. Proteins, terpenes, flavonoids, alkaloids, and other glycosides were crude extracts from which several phytochemicals were found, extracted from, and purified. Several plants contain antiviral compounds. For instance, rutin, a flavonoid glycoside found in numerous plants, is effective against the avian influenza virus as well as the HSV-1, HSV-2, and parainfluenza-3 viruses. Quercetin, abundant in plants aglycone of rutin, may prevent a variety of viruses that might cause sickness. The highly pathogenic influenza virus, dengue type 2 virus, HSV-1, poliovirus, adenovirus, Epstein-Barr virus, Mayaro virus, Japanese encephalitis virus, respiratory syncytial virus, and HCV are among these viruses. Its antiviral action mode was looked into in a few instances. Its capacity to inhibit the activity of a subset of heat shock proteins (HSPs) involved in viral IRES (internal ribosome entry site) translation is one well-known means of suppressing HCV. In response to stress, cells create proteins known as HSPs. Inhibiting HCV replication and the HCV NS3 protease in a subgenomic HCV RNA replicon cell culture is another approach. Inhibitions of rhinovirus pathogenic processes like endocytosis, viral genome recording, and protein synthesis are also caused by quercetin. According to a different study, quercetin acts in a more targeted manner, slowing down dengue virus type-2 replication but not viral attachment and entry processes. In addition, quercetin and three additional flavonoids – the 3,3′,4′,5,5′,7-hexahydroxyflavone in myricetin, the 3,3′,4′,5,6,7-hexahydroxyflavone in quercetagetin, and the 5,6,7-trihydroxyflavone in baicalein – effectively inhibited the reverse transcriptases of the HIV and Rauscher murine leukemia virus (RLV). Myricetin is a flavonoid that is found in a variety of fruits, berries, nuts, vegetables, and wild plants [45].

Table 1 Phytochemical activities of herbal plants with antiviral features

Herbal plants	Nature of extract	Disease	Phytochemical activity	References
Cyperus rotundus	Hydro-alcohol-by-pass extract	HBV	Cyperene-3, 8-dione, 14-hydroxycyperotundone, 14acetoxycyperotundone, and 3βhydroxycyperenoic	[69]
Viola diffusa	Ethanolic extract	HBV	2β-hydroxy-3,4secofriedelolactone-27-oic acid, 2β,28βdihydroxy3,4secofriedelolactone-27oic acid, 2β, 30β-dihydroxy-3,4-secofriedelolactone-27-lactone and stigmastane, and stigmast-25-ene-3β,5α,6β-triol	[70]
Vitisla brusca	Methanol extract	SA-11 and human (HCR3) rotaviruses	Resveratrol, piceatannol, transarachidin-1, and transarachidin-3	[71]
Ficus benjamina	Ethanolic extract	HSV-1, HSV-2	Rutin, 3-O-rutinoside, and 3-O-robinobioside of kaempferol	[72]
Curcuma longa L.	Curcumin plant extract	HTLV-1	Decreased regulation of Jun D protein in HTLV-1-infected T-cell lines	[73]
Tulbaghia violacea	Plant extract	Cardiovascular disease (CVD)	Inhibition of angiotensin-converting enzyme (ACE)	[74]
Helichrysum ceres	Plant extract	Cardiovascular disease (CVD)	Lowers blood pressure	[75]
Cucurbita pepo	Aqueous extract	Nonalcoholic fatty liver disease	α-glucosidase and amylase inhibition lowers hyperglycemia	[76]
Camellia sinensis	Methanolic extract	Diabetes mellitus	Epigallocathechin-3-gallate	[77]
Capparis spinose	Hydroalcoholic extract	HIV-1	Protein	[78]

(continued)

Table 1 (continued)

Herbal plants	Nature of extract	Disease	Phytochemical activity	References
Cyperus rotundus	Hydroalcoholic extract	HBV	Cyperene-3, 8-dione, sugetriol-3, 9-diacetate, 14-hydroxycyperotundone, 14-acetoxycyperotundone, and 3-hydroxycyperenoic acid	[69]
Diospyros kaki	Aqueous extracts	Human rotavirus	Lutein, vitexin, apigenin-7-O-glucoside, licoflavonol, glyasperin D, 18-glycyrrhetinic acid, and licocoumarone	[71]
Cassia alata	Crude extracts	Antioxidant protective effects	Hepatotoxin-induced liver damage in rats	[79]
Leucojum vernum	Methanolic extract	HIV-1	2-O-acetyllycorine and homolycorine	[80]

Elagic acid and myricetin from the aronia fruit were found to be effective in vivo and in cell cultures against a range of influenza subtypes, including an oseltamivir-resistant form. Many plants include the flavone aglycone apigenin (4′,5,7-trihydroxyflavone), which has a wide range of antiviral properties against the influenza A virus, enterovirus 71, foot-and-mouth disease virus, HCV, and ASFV. Notably, a number of plant-derived flavonoids are known to possess antiviral effects. Inhibiting the synthesis of nucleoproteins is one mechanism through which six phytochemicals (apigenin, baicalein, biochanin A, kaempferol, luteolin, and naringenin) out of 22 different flavonoids were effective against the avian influenza H5N1 virus in human lung epithelial (A549) cells. Baicalin, the glucuronide of baicalein, was also effective against enterovirus, dengue virus, respiratory syncytial virus, Newcastle disease virus, human immunodeficiency virus, and hepatitis B virus in addition to being effective against a variety of viruses. There are numerous ideas as to how baicalin prevents the spread of viruses. According to a study on the avian influenza H5N1 virus, baicalin, for instance, decreases the generation of HBV, the templates for viral proteins, and HBV-DNA synthesis and reduces IL-6 and IL-8 production without altering IP-10 levels. Oleanolic acid and ursolic acid, two triterpenoids that are abundant in plants, have been shown to inhibit enterovirus 71 replication and reduce the pathogenicity of HCV NS5B RdRp, respectively. Standardized elderberry extract, which also has *Sambucus nigra* L. as an active component, is a successful treatment for fever, colds, and influenza A and B [45].

7 Phytochemicals and Benefits of Selected Agricultural Residues in Livestock Nutritive Diet or Dietary Needs

7.1 *Malus domestica* Wastes Produced Nutritious Dietary Resources

Apple trash contains pectin as well as a wide range of other advantageous components, including carbohydrates, vitamin C, dietary fiber, and minerals. It has been demonstrated that adding apple pulp to chickens' diets considerably improves their productivity and fertility rates. Due to the high pectin content of apple pulp, it is essential to add multienzymes to the apple pulp ration to ensure that the pulp is more effective for chickens. Additionally, it has been claimed that feeding poultry apple pulp decreases their uric acid levels dramatically while increasing their blood glucose levels [46].

7.2 Nutritious Dietary Resources Derived from Avocado Skin and Seeds

Animal feed has occasionally included avocados. Animal waste feed made from avocados is derived from the fruit that is meant for human consumption. Because certain commercial requirements and industrial procedures are not followed, the seeds and skin are, however, thrown away. Unsaturated fatty acids, tocopherols, and other significant phytochemical components are abundant in avocados and aid animals – including pigs – in triggering healthy biological responses. According to Grageola et al., avocado eating helps to maintain the nitrogen and energy balances of young pigs. Furthermore, according to Wood et al., the taste and juiciness of avocados are regarded as sensory attributes that could influence the intramuscular fat (IMF) and fatty acid composition of meat. In their study, Hernandez-Lopez et al. contrasted the muscle of the treated pigs' experimental group with the muscle of a different group of pigs fed a control diet devoid of avocado waste. We investigated the oxidative stress, color stability, and fat content of pigs. Avocado consumption significantly reduced the amount of lipids in the LTL muscle, increased the content of unsaturated fats, and reduced intramuscular fat (IMF) [46].

7.3 Biorefinery of Waste from Plants

Each year, agricultural activities and subsequent food processing result in large amounts of plant-based waste. The majority of plant-based trash comes from agricultural residues other than grains, such as maize stover, wheat straw, and rice straw. Due to their wide availability and relatively uniform composition, these agricultural byproducts are appealing feedstocks for large-scale industrial biorefineries. The beverage industry, which produces a lot of pomace such as grape pomace and apple pomace, is the source of the second-largest amount of food waste. The pomace also includes significant amounts of high-value functional components, including polyphenols, essential oils, and vitamins, in addition to plant fibers. Waste made from plants mostly contains cellulose, hemicellulose, and lignin as its main structural components. Biofuels, organic acids, and nano-cellulose materials can all be made from cellulose. Hemicellulose can be broken down into the important chemical compounds xylose, xylite, and furfural. Lignin is a natural binder and glue that can also be utilized to create useful chemicals like phenols. Other deposits rich in plant-derived waste, such as sugars, proteins, and oils, as well as phytochemicals, should also be collected because they have the potential for a variety of uses in addition to structural compounds. Well-balanced essential amino acid proteins made from plant waste can be added to food to enhance its sensory and functional properties. For instance, soy protein has been used in imitation cheese, soy milk, and other goods. Two phytochemicals, polyphenols and carotenoids, have been related to health-promoting effects like lowering cholesterol and lipid oxidation. In addition to having health-promoting properties, the inclusion of these antioxidant chemicals in food matrices can increase the shelf life of those items and prevent the development of bad tastes. Vegetable oils present in plant-derived waste can be used to make sugar-based surfactants (such alkyl polyglucosides) with low toxicity and good detergent properties, in contrast to typical surfactants manufactured from fossil fuels. The extraction, purification, and manufacture of valuable chemicals, minerals, and biofuels from plant-derived wastes are therefore the subject of increased research [47].

8 Modern Approaches to Ameliorate Phytochemicals' Biogenesis to Mitigate Human Health Demands

Due to new knowledge of the hazardous ingredients and reactions contained in those synthetic medicines, many users of synthetic drugs and cosmetics are now becoming more interested in natural items. Due to their safety, ease of synthesis, and widespread availability, phytomedicines are among the natural therapeutic compounds derived from microorganisms, insects, and mammals that are acknowledged to have significant pharmaceutical value. The use of plant-based natural products in pharmaceutical, nutraceutical, and dietary supplement manufacturing has increased recently [48]. However, suggested plant molecular factories for the production of isoprenoids, including tocopherols and carotenoids, an important component of the human diet, have been made. Numerous plant-based natural products are utilized as medications to treat severe illnesses including HIV and newly emerging diseases that have recently gained popularity [49, 50]. The fact that natural phytoproducts are being used to treat neurological and cardiovascular disorders, such as Alzheimer's [51], diabetic neuropathy [52], and cardiomyopathy [53], is remarkable. Natural plant-based medication products are generated using contemporary safety precautions and isolation techniques, and they are intended to treat drug-sensitive and multidrug-resistant infections [54, 55]. Yellow fever [56], Zika fever [57], TB [58], and other protozoal diseases are all wiped out thanks to the improved mosquitocidal properties of natural phytomedicines.

The most recent figures for the years 1981–2014 show that around 42% of the 1562 newly approved medications are from natural medicinal plants [59]. Meanwhile, more than half of the 1073 novel types of small molecule medications that were licensed between 1981 and 2010 were natural bioactive chemicals [60]. It has proven difficult due to the complexity of the chemical compositions of natural substances, the wide variation in their structures, nonspecific adsorptions, false positive results, and the undetectable trace levels of active components [61]. These obstacles represent the actual challenges in the identification of bioactive components and prediction of their possible mechanisms of action. The good choice of in vitro and in vivo assays for screening of the plant bioactivity is a very important step in drug discovery from plants. The chosen bioassays should be characterized by simplicity together with good sensitivity and reproducibility. Numerous in vitro models using purified proteins, cell-based target-oriented or phenotypic assays, can be utilized for evaluation of the biological activities of natural products, in addition to the isolated tissues or organ models, and also in vivo preclinical animal models can be used [60]. Previously, plant-derived extracts and compounds were screened using the forward pharmacological strategy, which starts with in vivo animal tests, organ, tissue models, or bacterial preparations before moving on to in vitro testing to determine the mechanism of action. Prior to characterizing the molecular target of the active compounds, forward pharmacology, also known as phenotypic drug discovery, begins with the identification of phenotypic changes in complex biological systems to assess functional activity. Until the development of modern molecular biology technologies and the Human Genome Project, this traditional approach to drug discovery was the main approach [60]. A reverse pharmacology approach is used when the screening process begins with the testing of plant-derived compounds (or "libraries") against precharacterized disease-relevant protein targets in order to identify "hits," the biologically active compounds that are then studied using in vivo animal models with the goal of their validation. The only difference between the forward and reverse pharmacology techniques is the point at which the tests are used. Reverse pharmacology starts with the identification of the promising pharmacological target in order to produce the promising hit compounds, which are subsequently verified in vivo and regarded as target-directed drug discovery [62]. Molecular structures that may be recognized compounds produced from plants can be suggested to have a protein ligand binding property using in silico simulations. Compounds that perform well in in silico simulations can make excellent candidates for additional experimental testing. The success rates of applying virtual screening for activity forecasts are rising [63]. In silico simulations can be a useful filtration tool for both identifying ADME/T features and forecasting novel behaviors for a known natural substance [64]. New binding sites on proteins with known structures can also be found using these computational methods. To locate solvent-accessible protein surface cavities that serve as significant ligand binding sites and may afterward be computationally analyzed, pocket finders are used [65]. The biological effects of the active substances might be seen by controlling how signals are transmitted throughout the body and preserving a healthy metabolism. Alternately, they might work through interacting with enzymes and receptors, which are common disease-related medication targets [66]. The discovery of new therapeutic targets could be aided by the screening of biologically active natural compounds that target these enzymes and receptors, as well as by understanding the molecular activity of bioactive small natural molecules [67].

9 Conclusion and Future Outlook

Traditional herbal medicine practitioners have been verbally transmitting instructions on how to make herbal medicines for decades. Normally, they do not keep records, but the WHO has recently made public efforts to chronicle the use of medicinal herbs by conventional healers across the world. As a result, initiatives to record ethnomedical information on plants have risen in many developing nations. It has made it simpler to prove their pharmacological efficacy through science. People will be more knowledgeable and happy with effective medication treatment and improved health status after these regional ethnomedical formulations have undergone thorough scientific evaluation and dissemination [67]. Plants continue to hold promise as sources of medicinal medicines and as a foundation for the extraction of semisynthetic chemical compounds used in the food, cosmetic, and fragrance industries [68]. Additionally, the acceptability and use of plant-based health care products in the cosmetics business is growing. Therefore, medicinal plants have a significant role in the growth of the whole economy as a source of both commercial money and healthcare. The sales of herbal supplements and treatments are expected to increase in the next years, and meeting this need will be a booming market for herbals [66].

This implies that the pharmaceutical industry, medical professionals, and researchers will go to emerging nations like China, India, and others for their supply. Because these nations are the top exporters of raw herbal materials and have the widest variety of medicinal plant species. The use of plants in their whole or as pharmaceuticals will continue in the future due to their rising appeal as a secure and less expensive alternative to traditional medicinal agents.

Acknowledgment Authors would like to thank JIS University and JIS Group of Educational Initiatives for their immense encouragements.

Abstract

Since the beginning of human history, people all over the world have relied on the healing properties of plants to treat a variety of illnesses. To sustain life, carbohydrates, lipids, fibre, and protein are all necessary nutrients. Studying plants and their immediate environments is essential for establishing the nutritional significance of plants. The proximate composition of the food is made up of a number of different constituents, including the moisture content, ash content, fat content, protein content, and carbohydrate content. The food industry may be concerned with these food materials for product improvement, quality control (QC), or monitoring purposes. Rapid QC methods or more precise but time-consuming official processes may be applied. Assessment of a consistent and representative sample, as well as accurate results, requires meticulous attention to detail during the sample collection and preparation phases. The valuation methods for moisture content, ash value, crude lipid, total carbohydrates, starch, total free amino acids, and total proteins are presented in a clear manner. The chemical composition of the feed determines its potential nutritive value; hence, the proximate principles are established first in the evaluation of feed quality. Considering their nutritional relevance can help determine their value because many herbal plant species are used for food in addition to their medical properties.

TPC	Total protein content
USP	United States pharmacopeia
UV	Ultra-violet
WB	Water bath
WHO	World Health Organization
WSA	Water soluble ash

1 Introduction

Humans often use natural bioactive compounds derived from plants and soil to cure a variety of ailments [1]. Because of the physiological roles of these natural bioactive compounds, which are made up of phytonutrients and mineral elements [2]. Humans need to get enough nutrition, either in the form of a wide range of organic components or in a specific combination, in order for their physiological metabolism to work properly [3]. Energy-producing macronutrients such as carbohydrates, protein, and fat are necessary in large quantities, whereas critical micronutrients, including minerals and vitamins, are needed in small quantities [4]. Macronutrients are substances that are necessary in large quantities to provide energy. Microelements are added to many plant species to make them more therapeutic and less likely to get sick [5].

Herbal medications are in high demand around the world for basic healthcare because of the improved margins of safety and low cost that come along with using them [6]. The quality control (QC) of herbal medications results in a significant number of headaches. Therefore, the first and most important step is to select the appropriate kind of plant material, which includes substances that are effective in terms of treatment [7]. Herbal medicine manufacturing is done on a large scale, and the manufacturers face many challenges, including the use of low-quality raw materials, the absence of authenticating raw materials, the lack of availability of standards, the absence of quality control parameters (QCP), and the lack of adequate standardization procedures for individual medications [8, 9]. Consumers, on the other hand, are more likely to go for brands that adhere to established criteria. Therefore, standardizing Ayurvedic medications is an absolute necessity if one wants to ensure the efficacy, potency, safety, and purity of those preparations [10]. The use of combinations of herbal substances in traditional medicine further complicates the already complex issue of ensuring the quality of herbal products, which already present a number of their own particular challenges in this regard [11]. Therefore, when it comes to herbal treatments and goods, the standardization process needs to include the entirety of the relevant field of study, beginning with the growth of medicinal plants and continuing all the way to their clinical applications [12]. The World Health Organization (WHO) is actively involved in the standardization and quality control of herbal crude pharmaceuticals in order to oversee the physicochemical and proximate evaluation of these drugs [13]. Safety, efficiency, and sustainability assessments of completed products; documentation of safety and risk based on experience; provision of user product descriptions; and commercialization are all included in this evaluation [14]. In spite of the availability of current technology, pharmacognostic investigations, physicochemical studies, and proximate studies are both more reliable methods for the identification of plant-based medications. The proximate parameters are required for verifying the medications' identities as well as establishing their quality and level of purity [15].

Since many plant species valued for their therapeutic properties are also consumed for sustenance, assessing their nutritional relevance might shed light on their true value [16]. The majority of the diet is composed of carbohydrates, proteins, and fats, while minerals and vitamins play a relatively modest role. The nutritional content of plants is crucial because they make up the bulk of our diet [17]. In addition to these biochemicals, it has been noted that the moisture, fibre, ash, and energy values of different vegetables are significant for human health and soil quality [18]. In addition to containing pharmacologically significant phytochemicals, each species of medicinal plant also has its own unique nutritional content. We cannot live without these nutrients, as they are crucial to our bodily processes [19]. Carbohydrates, lipids, and proteins are examples of essential nutrients and biochemicals that help humans meet their energy and metabolic needs. Several substances having medical significance, such as vitamins, minerals, antioxidants, and anticarcinogens, are present in plants due to their diverse chemical composition [20]. Fibres, omega-3 fatty acids, vitamins, and minerals are all necessary for human wellness, and plants have enough of them [21].

The measurement of moisture content (MC), ash content (AC), crude fibre (CFi), total protein (TP), total energy value, volatile matter, and nutritional value has been widely used for over 160 years. Proximate analysis (PA) is a significant technique for the determination of the nutritional qualities of plant material and diets [22]. The quantitative measurement of bioactive molecules in plant materials and food products is referred to as "proximate analysis." Total protein content, crude fat, crude fibre, moisture content, ash content, total carbohydrates, total available energy, and nutritive value are mainly components of proximate analysis and may all be measured using a variety of methods, including extraction, Kjeldahl, Lowery, Biurets, Bradford, etc. [23]. It is possible to measure the relative quantities of protein, fat, moisture, fibre, ash, carbohydrate, nutritive value, and total available energy present in plant material using proximate analysis. These nutritional factors may be of importance to the food-service industry for a variety of reasons, including the production process, quality assurance, and regulatory compliance [24]. Total protein, total carbohydrates, crude fat, and crude fibre are all parts of plant materials that add up to the total amount of energy they provide. Moisture content and ash content are the only parts that add up to the plant material's mass. For determining the nutritional relevance of medicinal herbs, the proximate analysis of the plants plays an important role. The proximate analysis is a crucial index for determining how to categorize the nutritional value of a food material [25].

2 Moisture Content (MC)

The amount of water available in a plant component is referred to as its moisture content. In a broad variety of scientific and technical fields, it is employed as a tool. The moisture content can be determined by taking the dry weight and subtracting it from the initial weight. It is frequently expressed as the dew point temperature in grams of water per cubic metre of air (g/m^3) [26]. There are numerous procedures for measuring moisture content. Loss on drying (LOD) and Karl Fischer (KF) titration are the major procedures employed. Using conventional methods, the moisture content is measured in a hot air oven, as shown in the following scheme (Fig. 1) [27].

2.1 Moisture Content Protocol

1. Instantly weigh a pure sample and note the weight. This weight is called the "weight of the sample."

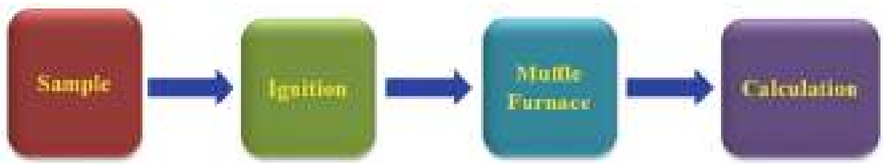

Fig. 1 Scheme of determination of moisture content

2. Dry the samples to a consistent weight using appropriate drying equipment.
4. Before using the sample, allow it to cool.
5. After allowing the sample to cool, reweigh it and write down the new weight. This weight is called the "dry weight of the samples."

2.2 Calculation

The following formula is used to estimate the percentage of moisture content of the sample plant material [26]:

$$\%\mathrm{Moisturecontent} = 1 - \frac{\mathrm{Weight}_{(\mathrm{dry\,sample})}}{\mathrm{Weight}_{(\mathrm{wet\,sample})}} \times 100$$

2.3 Relevance of Moisture Content

Moisture is an inherent constituent of crude drugs, and as much of it as is practically possible should be removed from the substance. One of the processes involved in transforming harvested plant material into crude pharmaceuticals is drying, which has a major impact on both quality and purity. The plant medicine is first garbled or washed to remove any remaining soil or debris, and then it is dried [28]. The drying of fresh material serves multiple purposes, the most important of which are to support the preservation process, "fix" the components (which means to stop the enzymatic or hydrolytic reactions from happening, which could alter the chemical make-up of the medicine), reduce their weight and mass, and allow further comminution, which is the process of crushing anything into a powder [29].

Inadequate drying makes it more likely that moulds and bacteria will cause spoilage, and it also opens the door for the enzymatic breakdown of active components. The typical moulds and bacteria that can grow on or in pharmaceuticals have relatively low moisture needs for their active growth; therefore, it is possible to find them on or in the drugs [30]. As a result, the process of drying the medicine needs to get the amount of moisture it contains down to a level that is below this crucial or threshold level. It is challenging to establish an accurate upper limit for the amount of moisture that can be tolerated in crude drugs [31]. This is due to the fact that enzymatic activity necessitates a certain level of moisture, and microbial demands for water content also vary depending on species and other environmental conditions (e.g., temperature, O_2 and CO_2 pressure, and light). Both the USP and the NF rarely make promises in this area [32]. If the humidity content of the medicine is decreased to 6% or less, however, it is possible to preserve the vast majority of medications without risk. One major exclusion is agar, which can have up to 20% moisture according to USP standards. Not only is the drug's final degree of dryness crucial, but also the rate of moisture removal and the circumstances under which it is eliminated are of equal importance [33]. If the rate is excessively slow, there is a high risk that a significant amount of spoilage may develop before the drying process is finished. As a result, drying should be completed as quickly as is practically practicable by the application of sound techniques. The amount of water content and other characteristics of the medications determine the amount of time needed for the drying process, which can range anywhere from a few hours to many weeks. The length of time that an elevated drying temperature is maintained is a crucial aspect to keep in mind because increasing the temperature accelerates destructive enzymatic reactions [34]. Most of these reactions, however, which are frequently encountered during the manufacture of crude medicines, only show a net effect up to about 45 °C. Yet, greater temperatures reduce the amount of time necessary for the drying process, and as a result, the amount of time that harmful reactions can take place is reduced as well [35]. Drying is accomplished through a variety of processes, the specifics of which might vary widely, but broadly speaking, drying processes can be natural or artificial. Physical ways include applying higher temperatures and/or lower pressures (vacuum), as well as infrared and radio-frequency radiation; chemical approaches include applying desiccants; or they may be biological, which involves the use of organisms that are genetically engineered to carry out the artificial method [36].

In most cases, the raw plant materials are subjected to drying and storage in order to serve as specimens for vouchers, in addition to serving extraction and isolation functions [37]. Although this is not the standard method of storage, the Ayurvedic Pharmacopoeia of India (API) does state that many quality assurance standards have been computed using the fresh plant matter without first drying it [38]. This was done without the plant material being subjected to heat. When it comes to stability, the percentage of moisture that a plant material has is quite essential. The following parameters are influenced by the amount of moisture present:

- Microbial growth, which is potentially harmful to the medicine and can take the form of either bacterial or fungal development.
- Enzymatic activity occurring within the plant tissues may pose a risk to the phytochemicals' capacity to maintain their structure.
- The process of drying the material results in a reduction in its overall volume, which is beneficial for the storage of the plant material.
- The process of further comminution and size reduction of the medicament is simplified after it has been dried [39].

3 Total Ash Content

Ash is defined as the inorganic by-product (residue) that remains after organic material in a sample has been ignited or completely oxidized, whichever occurs first. Measuring the ash level of a product is a component of its proximate composition for nutritional assessment, and it is a quality-related feature for specific food products owing to its enormous nutritional importance [40]. Furthermore, ashing is the initial stage in the preparation of a sample for particular elemental analysis, and it is also the most time-consuming. This laboratory activity uses the dry ash method in combination with an electric furnace in order to evaluate the ash content of a range of food items in a controlled environment [41]. The dry ash method is used to calculate the percentage of ash in the sample. The sample materials were burned at a high temperature in a furnace. The leftover inorganic substance is cooled, weighed, and employed to determine the mineral composition of the final product. In order to create an ash solution, 100 mL of 1 M HCl is used to dissolve the ash, and the resulting solution is centrifuged. It is common for people to look at the ash level of foods as part of quality assurance when they are trying to figure out how food works for their bodies. The ash content, measured in terms of a percentage of the dried sample's weight, describes how much of the sample is composed of ash [42].

3.1 Protocol

1. Place a certain amount of the crushed sample material, carefully weighed, in a suitably tarred dish (e.g., silicate or platinum), which has been earlier burned, cooled, and then weighed.
2. Combust the sample by progressively raising the temperature—not over 500 °C for 30 min in a muffle furnace—until it is completely devoid of carbon and ash.
3. Allow the sample to cool before weighing it.
4. Determine the ash content in mg/g [43].

3.2 Calculation

To calculate an estimate of the total ash content of a particular plant material, the following formula can be used [44]:

$$\text{Total Ash Content}\ \% = \mathrm{A}/\mathrm{B} \times 100$$

where A is the weight of ash and B is the weight of the dried plant.

The amount of ash in a crude medication is the amount of residue left over after burning. Typically, it stands for the inorganic salts that are already present in and adhere to the medicine, but it can also include inorganic material that has been added on purpose. In the case of certain specific medications, there is a sizable variation within rather tight bounds [45]. An ash analysis therefore provides information regarding the possible inorganic adulteration of a drug and serves as a basis for determining its identity and cleanliness. Tolerance levels for ash have been set for some legal medications. These standards typically stipulate a maximum allowable level of total ash (TA) or acid-insoluble ash (AIA). Total ash is what is left behind after burning; it consists of two types of ash: "physiological ash," produced when plant matter is burned, and "nonphysiological ash," which comes from ambient contaminants like sand and soil [46]. Physiological ash can be found in the sclereids of the pericarp of colocynth and the cork of liquorice, for instance. Nonphysiological ash includes things like sand or dirt that have been used as contaminants [47]. The main components of ash are carbonates, phosphates, silicates, and silica. Total ash content is not always a reliable indicator of the quality of herbal treatments because many plant components include large amounts of physiological ash, calcium oxalate in particular [48]. Hence, the amount of acid-insoluble ash in Chinese herbal medicine is still another indicator of its efficacy. Acid-insoluble ash refers to the percentage of total ash that remains undissolved after being exposed to aqueous HCl. In general, the amount of impure inorganic stuff can be gauged by looking at the ash or residue produced by an organic substance complex. In most cases, only a small amount of inorganic material is present that is not unpleasant and is difficult to eliminate throughout the purifying process [24]. Ashes help evaluate the potency and safety of powdered crude medicines. Ash that dissolves in water can be used as a proxy for the total amount of inorganic chemicals in a medication. The presence of the acid-insoluble ash, which is predominantly composed of silica, is indicative of contamination with granitic material [49]. Generally speaking, the ash level of fresh herbs is under 5%. In general, ash is not present in pure oils and fats, although it can be found in products like cured bacon (at 6%) and dry beef (at 11.6%) (wet weight basis). There can be zero to 4.1% ash in fats, oils, and lards, and between 0.5% and 5.1% ash in dairy foodstuffs. Ash content ranges from 0.2% to 0.6% in fresh fruit, fruit juice, and melons, and from 2.4% to 3.5% in dried fruits. Ash content is low (0.3% for pure starch and 4.3% for wheat germ) [50].

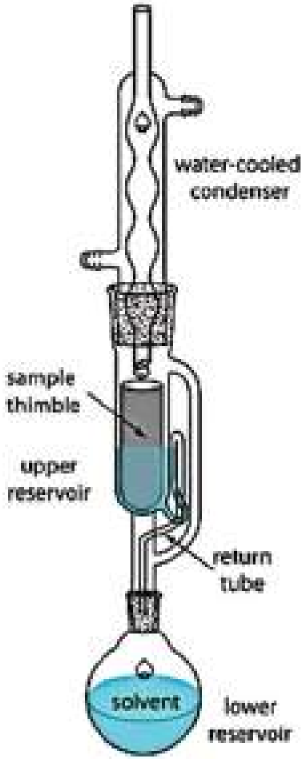
4 Crude Fat

The term “crude fat“refers to the raw or unprocessed combination of fat-soluble substances contained in plant material. The classic measurement of fat in fresh food is crude fat, often called total fatty acid or lipid content. Generally, the word “fat” refers to a group of compounds that are dissolvable in liquids like ether and chloroform but mostly immiscible in water. Fats are unsaturated lipids. Fats are normally solid at room temperature, whereas lipids are fluid [51]. The Food and Drug Administration (FDA) has officially described crude fats as molecules that have a lot of fatty acids in them, as well as triglycerides, phospholipids, non-esterified lipids, and salts [52].

4.1 Principle

Weigh out a specific quantity of the plant powder material. The thimble should be placed within the Soxhlet apparatus (Fig. 2). Put a dried, pre-weighed solvent flask underneath the apparatus, into which you will pour the needed amount of solvent before connecting it to the evaporator. Set the heating mantle to achieve a condensation speed of 4–5 droplets per minute, and then extract for 24 h at RT. After finishing, replace the thimble and use the apparatus to recover petroleum ether. Complete the extraction of petroleum ether in a water bath, followed by 30 min in a dried vacuum at 100 °C. Allow it to cool in the desiccator before weighing it [53].

Fig. 2 Soxhlet apparatus



4.2 Calculation

The following formula is used to determine the crude fat content of the particular sample [54]:

$$\text{Crude fat } \% = \frac{(W_2 - W_1)}{\text{Weight of sample}} \times 100$$

where W_1 is before weight of sample and W_2 is the weight of after weight of sample.

5 Crude Fibre (CF)

Crude fibre is a kind of insoluble fibre that may be observed in the eating component of the plant body. It is essentially cellulosic matter that has been produced as a by-product of the biochemical examination of vegetable ingredients. Crude fibre, on the other hand, is the non-soluble residue left behind after an acidic hydrolysis followed by an alkaline hydrolysis. This remnant comprises genuine cellulosic as well as insoluble lignin, among other things [55]. The amount of undigested lignocellulosic materials, saccharides, cellulose, and other components of this sort found in current diets is measured as “crude fibre.” These constituents have limited nutritional value but contribute the mass required for effective peristaltic movement in the intestine. The cellulosic component is mostly found as a by-product of the biochemical analysis of food [56].

5.1 Principle

A dried plant material that has been extracted with petroleum ether is first treated with a weak acid solution and then with an equally weak base solution. Then the residue is put in a petri dish after it is filtered [39].

5.2 Protocol

To prepare shade-dried plant material, weigh approximately 5 g into a flask. 200 mL concentrated H_2SO_4 is added to the flask and placed it under the condensation (Fig. 3) [57]. The mixture is brought to a boil in 2 min. Purified water is added to maintain volume and wipe away particulates sticking to the edges. Over low heat, it is heated for approximately half an hour, using antifoam if required. Using a vacuum filter, the water is filtered with filter paper in a funnel, and then it is rinsed with hot water to get rid of all the dirt and germs. Transferring the residues to the beaker, 200 mL of warm NaOH solution to the mixture is introduced. The container is replaced under the evaporator and returned to a simmer for 1 min. After 30 min of simmering, drain through a porous crucible. Rinse with hot water containing 1% HCl, then repeat with hot water. Using ethanol or methanol, crush the plant material

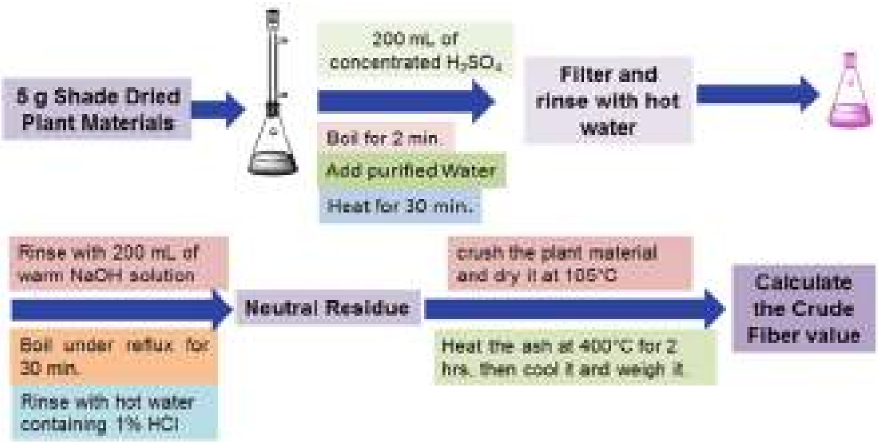


Fig. 3 Scheme for determination of Crude fibre

and dry it at 105 °C before cooling and weighing it. Heat the ash at 400 °C for 2 h, then cool it and weigh it. Calculate the crude fibre value using the following formula [43, 58]:

5.3 Calculation

$$\%\ \text{Crude fiber} = \frac{(\text{Wt. of Crucible} + \text{Dried residue}) - (\text{Wt. Crucible} + \text{Ash residue})}{\text{Weight of Sample}} \times 100$$

It is important to conduct an analysis of the diet that is consumed by humans or animals. More specifically, it is necessary to determine the amount of food that is ingested as well as the extent to which its dietary content is absorbed and maintained in the body. A digestibility study can be completed quickly using a procedure called quantification of faecal output. The determination of a food's crude fibre content is primarily done in order to get an idea of how much of food is indigestible by both animals and humans [59]. The organic compounds that are found in food or fodder that, while being subjected to treatment with chemicals at a certain temperature and concentration, maintain their insoluble state are typically referred to as crude fibres. They are believed to be adulterants due to the characteristics that they possess. A determination of crude fibre is carried out in order to identify any undesirable components that may be present in food or feed [54]. On the other hand, it is more practical to adulterate the medication powder as opposed to the herb or plant in its entirety. Synthetic compounds with the same chemical properties as those present in natural materials are often added for adulteration because they are less expensive. Oils of gaultheria and bitter almond, for example, may have methyl salicylate or benzaldehyde mixed into them. Both of these examples are examples of adulteration [43].

The crude fibre content of a plant can be estimated by boiling the plant tissue with a mild acid to remove the soluble material, then washing, drying, and weighing the remaining material to determine its cellulose, lignin, and cork cell content. The assessment of crude fibre is helpful in determining the amount of adulterants that are present in any given herbal sample, food sample, or fodder sample. The assessment of the crude fibre contributes to the process of distinguishing between the soluble and insoluble components, both of which are obtained from the various plant parts and the plant cells [47]. Crude fibres, unlike ash, have been found to be insoluble in water and resistant to digestion when boiled in H_2SO_4 and NaOH, indicating that they represent the more resilient sub-cellular structures within plants, together with certain less resistant components of cell walls, such as cellulose and pectin. Ash is the only component of the crude fibres that is not resistant to digestion. Chemicals like H_2SO_4 and NaOH are used in the primary technique for determining the amount of crude fibre present in a sample [48]. This technique requires that the material be processed in a specific order. The chemicals described above should be brought to a boil after being diluted to the appropriate concentrations. When the residue has been separated using filtration on a sintered glass filter, it should be washed, weighed, and ashed within a temperature range of 475–500 °C. The amount of crude fibre that was found in the sample is equivalent to the amount of weight lost during the ashing process [60].

6 Total Protein

Proteins are comprised of amino acids, which are organic substances formed of C, H, N, O, or S. Amino acids are the building blocks of protein. As per the FAO, proteins, like amino acids, are the basic components of muscle strength [61]. The quantity of proteins found in plant materials is referred to as the total protein. The Kjeldahl technique, the Dumas procedure, the Lawry method, and quantitative measurement techniques employing UV spectroscopy and refractive index methodologies are the most widely applied techniques to measure the protein content in plant materials and food products [62]. There are benefits and drawbacks to every approach. Direct amino acid testing, the Bradford technique, the Lowry approach, and the Kjeldahl technique were all used to quantify the proteins after they were separated using various procedures [63]. The Kjeldahl technique entails the use of a strong acid to digest food, which results in the production of nitrogen, which is then quantified using titration. As a result, a conversion factor is applied to the food's nitrogen content to derive its protein content [64, 65].

6.1 Kjeldahl Approach

Johann Kjeldahl designed the Kjeldahl technique in 1883. Basically, this is based on the idea that strong acids help food break down, which in turn releases nitrogen, which can be detected with the appropriate titration method [66]. Lab tests for Kjeldahl nitrogen or protein content may be done on a wide range of materials, including food and plant materials. Several scientific organizations, including the AOAC, EPA, and ISO, have approved and standardized the Kjeldahl method. Each stage of the Kjeldahl technique could be divided into three major components: digestion, distillation, and titration (Fig. 4) [26].

6.2 Digestion

By heating the sample in concentrated H_2SO_4, a homogeneous sample can be digested. The ultimate product is a solution of ammonium sulphate. The basic equation for the digestion of organic material is given as follows [39]:

$$\text{Organic}\,N_2 + H_2SO_4 \rightarrow (NH4)_2SO_4 + H_2O + CO_2 + \text{Byproducts}$$

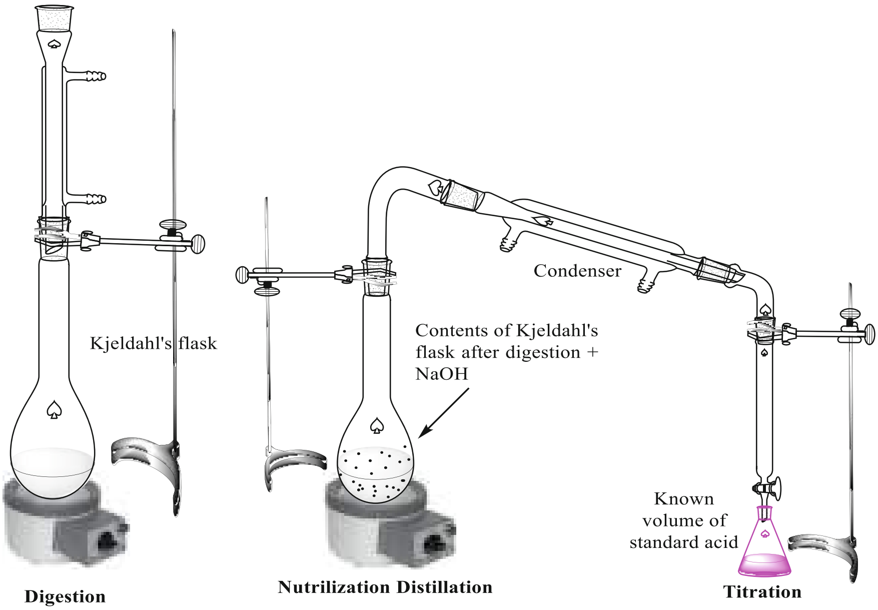

Fig. 4 Kjeldahl apparatus

6.3 Distillation

An excessive amount of base is mixed with the digested result, which causes the ammonium to be converted to ammonia, as shown in the equation given. Ammonia is recovered from the reaction product using distillation [26]:

$$(NH_4)_2SO_4 + 2NaOH \overset{\text{Heat}}{\rightarrow} 2NH_3 + Na_2SO_4 + 2H_2O$$

6.4 Titration

Titration is used to determine the quantity of NH_3 available in a receiving solution. The quantity of ammonia ions in the receiving solution may be used to estimate the nitrogen content of a sample material [64, 66].

Titration is classified into two categories:

1. Back titration
2. Direct titration

In both procedures, if ammonia is present in the distillate, the colour of the liquid will change.

6.5 Back Titration

A collection beaker containing a standard acidic solution that is calibrated is used to collect the ammonia. The received solution's excess amount of acid maintains its pH value, and back titration with bases is required to cause a change in the indicator [39]:

$$2NH_3 + 2H_2SO_4 \rightarrow (NH_4)_2SO_4 + H_2SO_4 \ \text{(No colorchange)}$$

$$\begin{aligned}(NH_4)SO_4 + 2H_2SO_4 + 2NaOH \rightarrow \ & Na_2SO_4 + (NH_4)_2SO_4 \\ & + 2H_2O \ \text{(Colorchange)}\end{aligned}$$

6.6 Direct Titration

When boric acid is used in place of a standard mineral acid in a titration, the ensuing chemical reaction is as follows [39, 43]:

$$\begin{aligned}NH_3 + 2H_3BO_3 \rightarrow \ & NH_4{}^+ + H_2BO_3{}^- + H_3BO_3 \\ & \text{(Colorchange)}\end{aligned}$$

When boric acid absorbs ammonia gas, ammonium-borate complexes are produced. Receiving solutions turn colours when ammonia accumulates:

$$\begin{aligned}2NH_4{}^+ + 2H_2BO^-{}_3 \rightarrow \ & H_2SO_4 + (NH_4)_2SO_4 + 2H_3BO_3 \\ & \text{(Color change in reverse)}\end{aligned}$$

7 Total Carbohydrate Content

Total carbohydrate content is made up of a variety of micronutrients and macromolecules such as dietary fibre, glucose, fructose, starches, proteins, total lipids or fat, and many others. All of these carbohydrate types are important for getting enough calories each day and living a healthy life, but eating too many of them, like any other macromolecule, can have negative effects [67]. Carbohydrates' primary role is to provide our body with energy so that it can perform critical functions such as muscle action, cognitive functioning, respiration, and many other processes [68]. Carbohydrates are mainly composed of saccharides, which are simple sugars. The majority of carbohydrate diets include polysaccharides, which are a group of many saccharides that are connected together [69]. The various procedures were employed to calculate the percentage of total carbohydrate content in the plant material assayed. Energy content is assessed by multiplying the percentages of protein, carbohydrates, and total lipids by 4 kcal/g and 9 kcal/g, respectively. There is an important role for carbohydrates in the upkeep and construction of the plant's materials. They are available as sugars as well as polysaccharides [70]. Diluted HCl is the first step in the process of breaking down carbohydrates into simple sugars. The dehydration of glucose or fructose to hydroxymethyl furfural occurs in a hot, acidic condition. Anthrone and this compound worked together to make a green-coloured product that could absorb at 640 nm [71].

7.1 Protocol

7.1.1 Extraction of Total Carbohydrate Content from the Plant Materials

(i) Weigh 1 g of the powdered plant material sample and transfer it to a bottom flask for testing.
(ii) Hydrolyse the plant material sample for 2 h in a boiling WB with 10 mL of concentrated HCl.
(iii) Then the bottom flask should be cooled down to 30 °C and neutralized with Na_2CO_3 until the bubbling stops.
(iv) Add distilled water to the boiled plant material to get the volume to 100 mL.
(v) Centrifuge the homogenization plant material at 2500 rpm for 5–10 min at RT until it has been moved to a centrifuge tube. Do this until it has been moved to the tube.
(vi) After that, remove the precipitate and employ it for estimating [39, 71].

7.1.2 Estimation of Total Carbohydrate Content in Plant Material Samples

(i) In the first, make a series of 1 mL to 5 mL of plant material and a standard solution in various test tubes.
(ii) Thereafter, transfer 0.5 and 1 mL of the carbohydrate extract of the plant material to 2 additional glass vials labelled.
(iii) Fill each test tube with DW to a volume of 1 mL.
(iv) Add 1 mL of DW to another test tube and label it as a blank solution.
(v) Next, add 4 mL of anthrone solution to each test tube along with the blank solution and mix well.
(vi) After thoroughly vortexing the test tubes, place them in a water bath for 10 min.
(vii) Each test tube should be quickly cooled down. Then, at 640 nm, measure the amount of greenish colour absorbed by the blank solution using a UV-Vis spectrometer.
(viii) This is how the percentage of total carbohydrate content in the herbal matter is found at the end of the process. It is expressed as GGE/100 g (gram glucose equivalent per 100 g) of the plant material sample [44, 72].

8 Total Energy Content

The total energy content of the diet and plant material is a significant characteristic to consider. The food we consume provides the energy our bodies require for exercise, communication, and work. Total energy content is the quantity of energy generated by the combustion or oxidation of one gram of plant material and is calculated in Kcal/g [73]. Total energy content provides the total available energy in plant sample material. Actually, total energy content is the sum of the values of total carbohydrate content, crude fat, and crude protein and is calculated using the factor of 16.736 for total carbohydrate content, 37.656 for crude fat, and 16.736 for crude protein [74].

8.1 Calculation of Total Energy Content

To quantify the total energy content of a food or plant material, multiply the number of grams of total carbohydrate content (TCC), total protein content (TPC), and crude fat (CF), respectively. Finally, combine the findings. Total energy content calculations are completed using a given formula [75]:

$$\text{Total Energy Content} = (\%\text{ of Crude protein} \times 16.736) + (\%\text{ of Crude fat} \times 37.656) + (\%\text{ of Total Carbohydrate content} \times 16.736)$$

9 Nutritive Value

As you eat and drink, you need certain nutrients to stay healthy. These nutrients are called “nutritional value.” Nutritional value, also known as “nutritive value,” is a measurement of how well these nutrients are balanced in the foods and beverages you consume and an indicator of a food’s influence on the nutritional content of the food [52]. This value is based on how quickly a meal can be digested as well as how many important components (protein, fat, carbohydrate, minerals, and vitamins) it has. The nutritive value of a food or plant material is the total amount of those nutrients that can be absorbed by the body and utilized for growth and maintenance [47]. Nutrient value analysis is used to evaluate adherence to standards for caloric intake, unhealthy fats, and salt, as well as to check the quantities of these macronutrients in meals. The nutritive value of plant material and foods relates to their composition and the effect of their ingredients on the health of the consumer. It talks about carbohydrates, lipids, proteins, vitamins, minerals, and salt consumption; as well as how much salt, fat, and sugar you eat [55].

10 Importance of Proximate Analysis

There are many diverse components in herbal medicines, and proximate analysis shines a light on numerous areas of detecting their physical and physicochemical features [76]. This kind of examination is useful for the initial identification of herbs, but it also provides insight into the quality of the plants employed in phytopharmaceutical formulations [45]. Fresh plants or plant components are typically the starting point, and these are then processed further through steps like drying and preservation. In several technical publications and monographs, pharmaceutical phytology details the steps necessary to convert a fresh plant or its constituent parts into a dried, potent remedy [47]. Phytomolecules are produced in the protoplast, moved across the plasma membrane to the tonoplast, and finally found in the vacuoles, where they are available to the cell's inhabitants in the form of cell fluid. Certain phytomolecules (like cellulose) with lipophilic components (such oils, balsams, and resins) are forced out of the cell via the plasmalemma [48]. Rose oil is produced when oil cells from the Lauraceae and Zingiberaceae families are dispersed in the cell fluid and chemically altered to produce a volatile oil that then fills the remaining space in the cell [77]. The Rutaceae family secretes lysogenic vacuoles, which dissolve with the cell wall, while the Umbelliferae family secretes schizogenic vacuoles, which expand intercellular gaps and produce etheric oil. The aqueous cell fluid is mostly used to store hydrophilic components, while lipophilic components are rarely found there [39]. When preserving plant materials, it is crucial to administer postharvest treatment in order to mitigate any negative outcomes (e.g., tubers, seeds, and certain dried fruit). Since the chemical components of medicinal plants can be altered by the quick or slow loss of water during processing (during the transformation of harvested plants into medications by drying and related features), understanding the postharvest physiology of crude pharmaceuticals is crucial [49]. So far, the low moisture content in the composition of the skin of the fruit or the seed case may impede the modifying processes. Extreme changes occur in the internal physical and physicochemical state of the cell as a result of water loss. Enzymes, which are usually present in the cell membrane of living plant tissues, interact with the active ingredients contained in the cell fluid when the plant cell dries. Many reactions, including hydrolysis, oxidation, and polymerization, might result from the interaction between a particular enzyme and its substrate [78]. While harvesting certain plants, the enzymes and active ingredients can react due to tissue disturbance because they are located in various (separate) cells. The idea behind drying raw pharmaceuticals is that they will be more stable in storage if they are dried out and no longer contain any moisture. Several decomposition-causing enzymes are stable during drying and can be reactivated by exposure to water [56]. Thus, the humidity level should be decreased to below the pharmacopoeia's minimum and maximum values. Many enzymes, including oxidases and peroxidases, are accountable for the formation of secondary metabolites in plants. The oxidation of phenols, unsaturated fatty acids, and terpenes is mostly attributable to these. Hydrolases can break down esters, glycosides, and polysaccharides. Morphine, quinine, and isomerases are essential for the manufacture of enantiomerically pure secondary phytochemicals such as the ergot alkaloids [79]. Medicines need to be dried as soon as feasible, and the enzymes must be denatured, to prevent them from being broken down by the body's natural processes. Drug stabilization refers to this process, which is rarely used in clinical settings. The results of an enzyme's work are not necessarily bad. Such procedures are often necessary for the release of active, aromatic, and other beneficial compounds [80]. After harvesting, there is no standard rule for how something should be dried or stored. To make standard-quality phytopharmaceuticals, low-quality raw materials provide a significant obstacle for botanical manufacturers. Although there are numerous botanical resources, official monographs rarely indicate any requirements for their use [70].

- Variations in the content of metabolites are seen due to geographical differences; these changes occur even when the standard is established and do not match those as stated in the pharmacopoeia.
- As herbal raw materials are so widely distributed, meeting demand is impossible.
- There is a risk that the extracted crude medicine is contaminated with insects or microorganisms, rendering it useless. Added preservatives or pesticides are left behind in unsafe quantities.
- It is challenging to sustain the excellence and clarity of herbal pharmaceuticals of pharmacopoeial quality due to the high demand for these drugs [39].

The quality of drugs is measured by how much of the active chemicals they really contain, whereas purity is determined by the absence of any foreign materials (organic or inorganic). Based on these elements, the product's functional and market value can be calculated. It is possible for a crude medication to meet all the statutory standards for purity and quality, depending on the concentration and nature of the ingredients [81]. In the process of gathering illicit substances from the wild, some inorganic or organic contamination is practically inevitable. Sand or other inorganic soil components are the primary inorganic materials in crude medicines. Metal, glass, or stone fragments may also appear, albeit less frequently. Very often, the organic material is from a species of plant that is not listed in the drug's official description, or it may be from a neighbouring plant of a different species [82]. Insects, moulds, and animal waste are some additional sources of contamination. These qualitative and quantitative parameters provide a clear idea about the distinctive features of crude pharmaceuticals. While these features are useful for informing the analyst on the nature and properties of crude medicines, it is only through further study of other parameters that it can be determined whether or not these substances are suitable [83]. The determination of several criteria, which have been discussed in more detail above, is a common practice in acquiring qualitative and quantitative data regarding the purity and quality of a crude medicament [59].

There is no conventional medicine equivalent to some plant-based pharmaceuticals, such as cardiac glycosides, which have been used for centuries. That is why studying medicinal plants and the bioactive chemicals they contain is so important. As a result, there has been a recent uptick in interest in herbal remedies [39]. Herbs continue to be valuable not just as treatments for a wide variety of human and animal illnesses but also as research tools for identifying novel bioactive chemicals that could be used to create novel pharmaceuticals. Several innovative treatments for cancer, high blood pressure, diabetes, infections, etc., have been produced thanks to the scientific exploitation of herbs used in traditional medicine [84]. Physical and chemical properties of plant medicines that may be used therapeutically include TA, AIA, WSA, SA, LOD, EV, FI, SI, CFC, bitterness value, haemolytic activity, and foreign organic matter [85].

Herbal formulations used in any medical system must first undergo the processes of authentication and standardization [86]. The class of base substances used in the formulation of herbal products is essential for the development of drug standardization. Herbal medication ingredients are typically traded as intangibles such as roots, bark, twigs, flowers, leaves, fruits, and seeds, making it difficult to visually authenticate the material utilized and leading to widespread adulteration [87]. Due to their varied composition—whether they are whole plants, sections of plants, or extracts from these sources—natural product standardization is a challenging endeavour. Quality reproduction of herbal products relies on strict quality control of raw materials. This has led to a surge in recent years in the standardization of many herbal medicines thought to have therapeutic effects [60]. False labelling is the first step in the dangerous use of any natural or herbal remedy. It is not uncommon for people to use the same colloquial name to describe two or more species that are, in fact, very distinct from one another [88]. Research into the pharmacognosy of medicinal plants, especially their physicochemical composition, holds the key to resolving all of these issues. Standardization and quality control of herbal products are defined by the WHO [89] as the procedures involved in the physicochemical assessment of crude pharmaceuticals, the safety, effectiveness, and sustainability evaluation of the completed product, the promotion of a product, the dissemination of information about that product to consumers, and the recording of the product's risks and benefits based on actual use [90]. All factors that affect the quality of herbal medicines should be considered in the standardization process [91].

11 Quality Control Aspects

In almost all conventional medical systems, quality control has been provided by the vigilant observation of trained professionals. They need to rethink their approach to quality assurance and the development of innovative techniques in light of the contemporary context. Hence, evaluating the efficacy of traditional herbal remedies is a hot topic right now [92]. It is necessary to explore the criteria associated with standardization in different batches in order to set a boundary for the reference standards used in quality control and quality assurance of herbal drugs. As a result, the established micro- and macro-standards can be used as indicators of the medicine's authenticity [60]. This is because several types of bacteria and mould, many of which originate in the soil, can be found on medicinal plant components, so determining microorganisms of great importance will be useful in identifying and authenticating the plant material, in addition to the microscopic method, which is the most cost-effective for authenticating the original content by tracing its origins [39]. When establishing criteria for selecting standard substances and carrying out quality control, it is vital to keep in mind that various ingredients in herbal medicines may have differing degrees of impact on the overall quality, safety, and effectiveness of the product. Contents such as moisture, ash, volatile matter, ash, fixed carbon, etc., are revealed. Water and organic materials are burned off during cooking, leaving behind an inorganic residue called ash that can be used as a proxy for the total mineral content of the food [24]. When compared to other components of food, minerals are not only stable but also resistant to heat. True drug samples may have total ash values that fluctuate over a wide range due to the presence of varying amounts of natural or physiological ash. A plant's ashes can reveal the types and amounts of minerals it once contained. Thus, the proximate study of herbal medications is a crucial topic in the field of natural product quality control [56].

11.1 Quality Assurance

The wild populations of several crucial plant species used in medicine have been depleted due to overharvesting, making it impossible to ensure a reliable supply for the foreseeable future. Health problems (whether caused by changes in lifestyle or not) are a major concern in the current setting of increasing urbanization and the resulting changes in lifestyle [84]. If and when demand for herbal remedies increases, it is anticipated that phytochemicals with supposed therapeutic capabilities for lifestyle-allied disorders will experience strong demand. Most of the raw materials used in manufacturing are delivered in bulk, which poses significant security risks. The distribution of raw materials in large quantities involves numerous middlemen. Little to no toxicological or carcinogenic testing is done at any point in the manufacturing process, and there is little oversight over the quality of the botanicals used [93]. There are a number of quality control measures in place to ensure that only the highest quality botanicals are exported, but concerns are especially high with regards to countries still in the development stage. Understanding the stringent quality standards of the herbal drug industry is crucial to the preservation of these rare plants for medicinal purposes [94]. There are two main ways to acquire medicinal plants: wild gathering or farming. The cultivated material is better suited for industrial applications like drug manufacturing. In the beginning, there are producers and primary collectors; then, there is an intermediary supply to local contractors; then, there is a supply to regional and large wholesale markets; finally, there is a supply to manufacturers via specialized suppliers; and finally, there is a supply to the end user. Yet, the supply chain must be optimized for effective output [94]. An examination of the current system's flaws reveals key areas for more regulatory oversight: First, the use of standardized cultivars; second, the use of standardized cultivation techniques; third, the superiority of raw ingredients at the source (as provided to manufacturers); fourth, the management of post-harvest treatment and processing; and fifth, the use of standardized formulations in accordance with regulatory mandates [39]. The plants include several phytoconstituents that contribute to their bioactivity, which presents a significant problem in the domain of standardization. It is not enough for a product to consistently have the right amount of active ingredients; they also need to be produced in a way that allows the body to absorb them. For the cultivators to make a profit, they need access to standardized genotypes that produce high levels of the active component. As a result, “niche” farmers who specialize in growing plants of concern for corresponding and unusual treatments can thank the procedures necessary for the ideal production of the active compounds for their success. Several older medicine formulations do not adhere to modern standards of practice [95, 96]. Those who do not have insufficient and ineffective quality checks that would provide the consumer with confidence in the drug’s efficacy. Some important steps that can be taken to help developing nations establish more profitable trading practices for herbal medicine are: careful processing, value-adding, and product display after collection; farmers and businesses working together to maximize farmers’ incomes; studying and developing new types of therapeutic plants; and encouraging regional or local farmer cooperation to ensure a reliable supply of inputs [97].

As many different substances may go into making herbal medicines, it might be difficult to standardize quality assurance standards and devise a foolproof validation process. The quality and amount of medicinal plants’ active ingredients can vary from harvest to harvest, even if the plants were harvested from the same location [98]. Moreover, various factors such as plant age, region of origin, harvest time, drying method, storage environment, production process, packing, etc., influence standards. Because the entire process of making a medication from a plant is considered an active entity, it is difficult to create appropriate guidelines [99]. The WHO procedures created in 1991 assist as a quality control mechanism for herbal medications. The most important parts of the WHO guidelines are: (1) ensuring excellence by checking raw plant material, plant preparation, and the final product; (2) ensuring durability by establishing a shelf life; (3) authenticating safety primarily through practice and toxicology studies; and (4) providing a recognized indication of productivity through activity assessment (in animals and humans). Although the WHO has offered guidance on how to evaluate herbal remedies, it is not within its scope to do so [93, 100]. Instead, the responsibility for ensuring compliance with WHO standards falls on the manufacturer, compendia review, and regulatory bodies. The production process must be monitored and assessed by regulatory agencies in accordance with the current regulatory regime [101].

12 Safety Concerns for Herbs

The chemical structures of herbal remedies are extremely diverse and complex. The use of natural compounds to alter organic capacity has also garnered much interest. They have been useful in the fields of chemistry, biology, and healthcare, where they have been essential in the identification of new therapeutic targets [102]. Natural products continue to play an important role in a wide range of therapeutic improvement and research initiatives because of their synthetically diverse variety and innovative mechanisms of activity. Some of the most important pharmaceuticals in a social insurance system are found among these natural goods, which have undergone fascinating and important changes in their ability to interface with numerous modified natural targets [103]. For instance, tiny compounds, which are produced by plants, microbes, and animals, have played a significant role in medication development. In addition to their widespread use in developing nations, plant-based healthcare solutions are also widely employed in affluent nations, either as a primary treatment method or in conjunction with traditional medicine [104]. The use of medicinal plants has long been a part of both conventional medicine and folk medicine, with several herbal prescriptions available for their use in the prevention and treatment of various disorders. It covers everything from widely used home remedies to professionally prepared herbal concentrations [105]. New biologic breakthroughs, including pharmacogenomic, metabolomic, and microarray techniques, can be used to conduct the in-depth examination of the pharmacological properties and safety of herbal-inferred therapies that is necessary [99, 106]. To add insult to injury, many people use herbal supplements along with their regular medication without telling their doctor, which can cause dangerous herb–drug interactions [107]. Herbs are becoming increasingly popular as dietary supplements and OTC medicines, leading to a greater need for scientific and clinical information for product assessment [108]. Several of the herbal medications currently in use have been around for a long time and have proven effective. Specific scientific backing is required to address the safety and effectiveness of the complex blend of herbal preparations and properly document trial data [109].

Phytoconstituent safety assessments and interactions with conventional drugs are subject to varying regulatory standards across nations [103]. Herbal medicines with known interactions with CYP isoforms must submit documentation to regulatory bodies prior to commercialization. Herb–drug interactions occur because various phytoconstituents have been found to either inhibit or activate cytochrome. Several phytoconstituents have been reported to interact negatively with standard pharmaceuticals. Many cases of herb–drug interactions have been documented [110]. This occurs most frequently when a patient conceals their herb use from their doctor. In some instances, the lack of sufficient scientific documentation and public knowledge may be to blame. Patients have been documented to experience a wide variety of side effects when exposed to phytochemicals such as allicin, quercetin, and silymarin [92, 111]. Patients may be using additional herbal remedies or nutritional supplements in addition to their prescribed medications without realizing it. Hence, we need to have an in-depth understanding of the pharmacology, mechanistic deed, drug relations, safety, and usefulness of herbal remedies to achieve the greatest possible benefit while minimizing the undesirable side effects [105]. The public's understanding of the potential for adverse reactions to drugs has expanded to include secondary metabolites seen in herbal remedies. It is obvious that combining natural items can interact and change the therapeutic advantages of these regularly used medicines [112]. Herbal medicines and OTC drugs may interact with drug-metabolizing enzymes in dangerous ways, leading to potentially fatal side effects if used together [113]. In order to better comprehend the prospective for herb–drug relations, studies on drug-metabolizing enzymes have been conducted [6].

12.1 Quality-Related Safety Issues

Plants may or may not include poisonous chemicals in addition to pharmacologically active molecules. The wrong herb may have been used, among other possible causes of toxicity in herbal remedies. The presence of other medications, hormones, or heavy metals in the soil can lead to this effect in plants. Providing safe herbal medicines and healthcare herbal products is vital to quality assurance [113]. The literature was scoured for accounts of side effects and possible drug interactions, and this list was developed. These side effects are plausible in patients taking herbal medicines, especially when used for an extended period of time or at large doses. The quality of raw herbs is crucial to the efficiency and safety of herbal medications. In contrast, medicinal plant raw materials and their definitions of quality vary greatly in terms of both the quality and quantity of their phytochemical profiles. That is why it is crucial to nail down the quality metrics that are inextricably related to reliability [114, 115]. Achieving uniform pharmacological action and facilitating significant contrast and meta-analysis of clinical records requires strict adherence to the harmonized quality standards. Traditional and modern herbal remedies sold commercially now have their constituents tested for quality and safety more than ever before. However, the safety and effectiveness of botanical medicines must be considered in any quality assurance paradigm for botanicals [109]. Depending on the context in which herbal products are being used and the health claims being made for them, a variety of terminologies, definitions, and quality factors are in use around the world. Complementary, alternative, and nonconventional medications, such as herbal products, are generally centred on traditional remedies, such as TCMs, Ayurveda, Siddha medicine from India, and Kampo medicine from Japan [6]. The dried, untreated, entire, or fragmented plants or plant matter are the starting point for the identifying descriptors in pharmacopeial herbal monographs, which are still relied on today by the therapeutic herb business and herbal component makers. Macroscopic, microscopic, and organoleptic analyses of arranged and dehydrated plant pieces revealed the identity of the constituents [116]. Yet, when material is fractured or sorted, evidence on leaf shape, extent, and variety, phyllotaxy, floral characteristics, and placement in the inflorescence may irreversibly vanish. This is especially true for specimens that lack the flowering and fruiting sections of the plant. These monographs serve as an identification guide, but they are useful only after the entire plant has been verified as genuine [39].

13 Conclusion

Proximate analysis of plant materials provides information about their total ash, moisture, protein, crude fibre, crude fat, carbohydrate, nutritional value, and energy content. It is vital to check the plant material's moisture content before eating it. The physiochemical components of plants and foods are influenced by the presence or absence of water, which in turn affects their flavour and texture when stored. Moisture content impacts food makers' processing and analysis. A plant material's properties, storability, utility, and quality depend on its moisture level. In agriculture, medicine, and insecticides, accurate moisture content evaluation is essential to product quality. The overall ash content of plant material helps estimate mineral reserves. Energy comes from crude fat in numerous ways. Crude fibre is the ratio of people's current diets' cellulosic, pectic, lignin, and other undigested elements to how much they eat. Crushing and separating grain from its vegetative condition is tested using crude fibre. Ripe plant-based foods have more crude fibre, which helps determine biological taste. Healthy eating promotes a healthy lifestyle, appropriate growth, development, and maturation, body mass maintenance, and a reduced chance of major illness. All of these improve health. The proximate study of medicinal plants is crucial for establishing their nutritional value. Proximate analysis is a useful indicator for categorizing the nutritional value of dietary ingredients. Herbal medicine proximate analysis is thus an important area of inquiry in the study of herbal material quality assurance.

Abstract

The use of herbal medicines and herbal products has significantly increased in recent times and contributes to the socioeconomic sustainability of the rural and suburban populace. The socioeconomic importance of herbal medicine includes addressing health issues, revenue generation, cultural development, insights for novel medication development, and indigenous knowledge sharing and exchanges. The commercialization of medicinal plants enables traders in the locality to offer their products and expertise at a fair and reasonable price, thereby, making returns to support their family and community. Every aspect of herbal medicine formulation and use value chain (i.e., cultivation harvesting, processing, formulation, packaging, sale, use, and waste disposal) has diverse socioeconomic relevance from the local to global scale. However, the value chain sequence varies at different scales. For instance, at the local scale, it may be from smallholder markets to national and international trade with varying levels of actors along the sequence. Apart from their economic values, medicinal plants also serve as a source of employment and sustainable sourcing and stimulate quality control of the medicinal product. An innovative approach to subvert the increasing length of the value chain, the blockchain approach, can be employed. The concept of blockchain replaces the analog ledger approach, and it is a system that is built on decentralized data storage on several users, each forming a network node. This review, therefore, elaborates on the economic importance, value chain, recent approaches, and quality control of herbal medicine plants and products for sustainable production.

1 Introduction

Herbal medicine refers to plant-derived substances that exist naturally and are used to cure ailments in local or regional healing practices. They are a combination of complex organic compounds that may be derived from plants either in raw or processed portions of plants [1]. Herbal medicine can be traced back to ancient societies. Herbal medicine entails the use of plant parts or whole for the formulation or as medicine to treat, manage disease conditions, and improve overall health and wellbeing [2–5]. Herbal medicines are described by the World Health Organization (WHO) as medical products which are labeled and contain active substances that may contain parts of plants that are seen aerially or under the ground, or other plant mixtures or materials [6–8]. Herbal medicines can be utilized as self-care solutions for everything from insomnia, stress, and mood problems to digestive issues, colds, and flu. Herbal therapy can be used to prevent and cure several ailments in humans, such as asthma, eczema, premenstrual syndrome, migraine, chronic fatigue, rheumatoid arthritis, cancer, menopausal symptoms, and irritable bowel syndrome. Many disorders are treated using herbal medicine. For example, the bark of willow plants contains a high concentration of salicylic acid, an active metabolite of aspirin [9]. It is estimated that over 80% of people worldwide use herbal formulations as a main health care system [10–12], which is rapidly increasing due to the toxicity and unpleasant responses associated with modern allopathic medications, which has also contributed to a quick rise in herbal drug makers [13]. Natural herbs were widely utilized in ancient times to cure and prevent a variety of illnesses. Based on the pros and cons in this discipline, new herbal medicines that are useful to health with no or little adverse effects are developed [14]. Since its inception around 8500 BC, medicinal plants have given humans curative medicines [15].

A large number of conventional medications currently on the market, used to treat both acute and chronic disorders, have been inspired by medicinal plants [15]. Substances derived from medicinal plants are frequently synthesized into synthetic derivatives utilized in clinical pharmaceuticals, hence broadening the variety of conventional medicines [16]. Many plants have been reported to possess pharmacological properties, particularly inhibition of microbial growth [17–33] and control of insects such as mosquitoes [34–40]. Herbal medicine has various advantages, including being a candidate for new antiviral, having fewer adverse effects than synthetic medications, and having a remarkable ability to inhibit the reproduction or synthesis of specific virus genomes [41]. Herbal medicines contribute to social, economic, and environmental sustainability in a variety of ways. Herbal medicine is important in promoting bioeconomy, which encompasses various value chains and economic activities which are based on biodiversity [42, 43]. Herbal medicines have always accounted for a significant portion of the medicine market. The global trade in medications derived from medicinal plants was projected to be between USD 32 and USD 43 billion [44]. These plants and the drugs they produce are prescribed in both developing and developed nations. To increase their reliance on their pharmaceuticals and build their economies, this should also be prioritized by other emerging nations. The growing nations must comprehend the worth of their native medicinal plants and their economic significance to achieve this [45, 46]. The promotion of their valued plants can thus draw in investors for the creation of pharmaceuticals and aid in the development of their own herbal medicine [44]. Therefore, using medicinal plants will go a long way in increasing the income of a country and enable the populace to have access to medicines, enhancing the nation's health services [44]. To this end, the value of herbal plants and their importance in the economy cannot be neglected.

This chapter addresses the socioeconomic values of herbal medicine, its concepts, value chains, challenges, and heavy metal contamination, and the recent approach to the value chain approach which involves the blockchain system. The information was synthesized from an intensive literature search and presented in a simplified approach for better understanding and easy assimilation. The information herein will go a long way in promoting sustainable socioeconomic activities and conscious practices for the distribution of herbal products in a technologically driven manner. Issues about prompt delivery of herbal medicine and reduction in the length of the value chain will also be discussed.

2 Social Values of Herbal Medicine

The practice of medicine is very important to the sustenance of sociocultural norms that hold many societies together around the world and has been successful in protecting and maintaining the health and wellbeing of many societies. The practice also has many socioeconomic aspects which are beneficial for the advancement of societies. The values cannot be overemphasized as over 90% of the medicines originate from plants. In ancient times, plants were used to address several diseases and ailments, most especially in areas that are thickly forested and hilly. Such areas can house diverse species which can be used for herbal purposes as well as generation of income and livelihood sustenance for the poor [44]. Those in the rural areas that have a vast knowledge of medicinal plants and this indigenous knowledge about the economically important plants are applied to treat various ailments that may occur to poor villagers.

For socioeconomic development, it is important to understand the scientific cultivation and uses of medicinal plants in a sustainable manner. Conversely, the scientifically cultivated herbal plants for commercial purposes are very few [38]. The medicinal extraction is very low and the abundance of herbal plants is reducing daily as a result of deforestation activities, urbanization, industrialization, overgrazing of lands, and intensive harvesting of plant species that are rare and endangered and have great medicinal purposes. The lack of support from the government, environmental ministries, inadequate management strategies, and institutional framework has greatly affected the management of valuable herbal plants. Also due to a lack of information about the genetic resources and the values of herbal plant species, countries have failed to enforce sustainable management strategies [26–29]. Presently, a large number of herbal plants are now extinct while a large number are considered threatened.

2.1 Economic Importance of Herbal Medicine

Herbal medicine, also called botanical medicines or phytomedicines, is a term used to describe herbs, their materials, the procedure of preparation of herbal materials, and already completed herbal products. These materials/products usually contain active components that are derived from the parts of plants or the plant materials from which the raw materials are obtained [7]. Examples include plant seeds, roots, bark, leaves, berries, or flowers [47]. Table 1 presents some plant materials and the active ingredients they contain.

Medicinal plants are known to be the source of many medications used in modern and conventional medicine with huge economic value and the driver of huge sectors. For instance, an herb, the foxglove plant (*Digitalis purpurea*) has been used since 1775 to cure cardiac glycoside as it is used to produce digitalis. Pure honey is a good product for the treatment of infected wounds and can act more quickly than usual. Similar to this, traditional birth practices use plant extracts from South Africa that have calming effects on the muscles. Table 2 presents the list of some herbal materials used in Nigeria and their economic importance. The commercial development of herbal medicinal plants has geared the increase in several situations around the value chain production, such as the scale of manufacture, convenience in terms of storage, and prompt delivery of cost-effective pharmaceuticals to low-income

Table 1 Herbal plants and active ingredients

S/N	Herbal plant(s)	Active ingredients	Uses	References
1	Meadowsweet plant (*Filipendula ulmaria*) and white willow bark	Salicylic acid	For the production of aspirin	[47]
2	Sweet wormwood (*Artemisia annua*)	Quinine	In the manufacture of antimalarial medications	[48]
3	Quinine tree (*Cinchona pubescens*)	Artemisinin	In the manufacture of antimalarial medications	[48]
4	Periwinkle (*Catharanthus roseus*)	Vinblastine and vincristine	In the production of an anticancer medication called vincristine	[49]
5	Opium poppy (*Papaver somniferum*)	It produces morphine, codeine, and paregoric	To cure diarrhea and pain-relieving medications	[49]

Table 2 Some herbal plants and their socioeconomic importance

Herbal plant	Functions	References
Basil (*Ocimum gratissimum*)	Cures diarrheal disorders	[50]
Poison devil's pepper (*Rauwolfia vomitoria*)	For hypertension, stroke, sleeplessness, and convulsions	[50]
Dry seeds of *Carica papaya*	For addressing intestinal parasitosis	[51]
Bitter kola (*Garcinia kola*)	Used in treating osteoarthritis due to its analgesic and inflammatory effects	[51]
The gel of aloe vera (*Aloe barbabensis*)	Used as an effective benzyl benzoate	[52]
Gingko (*Gingko biloba*)	It can treat patients with mild dementia and Alzheimer's disease, bone healing, anxiety, depression, eye health, and inflammation	[52]
Turmeric (*Curcuma longa*)	Preventing cancer and skin diseases, halting DNA mutations, and preventing pains caused by inflammatory diseases	[51]
Evening primrose oil (*Oenothera biennis*)	Used for mild skin conditions, breast pain, menopause, inflammation, diabetic neuropathy, and multiple sclerosis	[51]
Tea tree oil (*Melaleuca alternifolia*)	It is used to prevent athlete's foot, cuts, dandruff, and insect bites	[53]
Purple coneflower (*Echinacea purpurea*)	Used for colds, bronchitis, immunity, and upper respiratory infections	[53]
Grapeseed extract (*Vitis vinifera*)	It is used for treating cancer, edema, leg vein circulation, blood pressure, and lowering cholesterol	[52]
Lavender (*Lavadula angustifolia*)	It is used as an anti-stress, in the treatment of anxiety, lower blood pressure, and migraine	[52]
Chamomile (*Matricaria chamomilla*)	It is used to address stress, anxiety, insomnia, and cancer	[51]
Coriander (*Coriandrum sativum*)	It is rich in antioxidants and can cause urine retention	[51]
Fennel or saunf (*Foeniculum vulgare*)	It is used to treat cough, prevents bad breath, improve milk supply in women that are lactating, improves eyesight, and control cholesterol levels	[51]
Fenugreek (*Trigonella foenum-graecum*)	It controls cholesterol levels, purifies blood, lowers blood pressure, increases appetite, and cures diabetes and joint pains	[50]
Mint (*Mentha piperita*)	Boosts immunity, improves respiratory health, keeps mosquitoes away, and enhances mood	[50]
Tulsi/holy basil (*Ocimum tenuiflorum*)	It is an anticancer, treats indigestion, good for hair loss, diabetes, and heart diseases	[50]

nations. With all of these promising attributes, the commercial scale of production of herbal medicine can be promoted [54]. Food and Agricultural Organization has published the conditions and trends surrounding the production and commercialization of medicinal plants. This publication elaborates on the production and market value of medicinal plants and presents the diverse opportunities and challenges around the trade of medicinal plants to the world at large [55].

WHO [56] stated in its report that 30% of the entire brand of pharmaceuticals sold in the world today contained ingredients that were sourced from different parts of plant materials. About 600 million USD was estimated to have been incurred on the global production of herbal products in 2002, and the health care needs of about 80% of the population in developing nations depend solely on pharmaceuticals produced from plants. Therefore, the interests of countries with low income can be motivated by the use of medicinal plants, and this can form an important component in the developmental strategy of the economy and sustainable development. An estimation of 4 billion people, which amounts to about 80% of the population of the world in most developing countries, solely relies on the products from herbal medicine as a fundamental source of health care. Consequently, the practice of traditional medicine using herbs has been seen as a major part of their culture and traditions in rural communities [53]. Over 90% of the 1300 medicinal plants obtained from the wild are utilized in Europe, while 118 out of the 150 major prescriptions originate from natural sources in the USA [57].

Similarly, it is believed that pharmaceutical products in most industrialized countries also rely indirectly on medicinal plants [58]. In Asia, their medicinal plants account for a total export volume of around 50%, and the earnings from traditional medicine globally is about 45% [59]. Nigeria is a country that is richly endowed with diverse species of indigenous plants, which can be used in herbal medicine to address diverse diseases and heal different injuries. The issue of poverty can affect education, freedom, and health, in addition to the economic aspect [60], and is very evident in developing nations where the infrastructure and delivery of service is very poor. Rural poverty can be a major cause of inequality and intense degradation of the environment [61]. The livelihoods and eradication of poverty can be achieved through the field of agroforestry and the incorporation of herbal medicines in all its forms. The world can therefore create systems that are resilient to the worrying concerns about the environment and prevent disasters of all sorts [60].

The commercialization of medicinal plants has significant economic importance because it enables traders in the locality to offer their well-known products and expertise at a reasonable price, thereby making more returns to sustain their families and contribute to the social and economic development of their communities. Markets may also be established, which may have a national or global outreach where products that are of importance and newly identified can be advertised and sold to people. Nowadays, big herbal drug manufacturers are increasing their demand for medicinal plants as crucial raw materials. As a result, there is a great potential for creating jobs for those who are unemployed because the collecting, processing, and delivery of medicinal plant products demand a large input of the labor force [62–67]. Thus, by improving conventional processing by industries, cash earnings for locals can be raised [68]. Though only a few species of medicinal plants are manufactured on a large scale, cultivation sometimes may include the raising of medicinal plants with low demand for them globally [69]. China, the world's largest cultivator of medical plants, only plants on a bigger scale of between 100–250

Fig. 1 Economic importance of medicinal plants

species, and the wild environments produce about 80% of medicinal plants [70]. Europe cultivates medicinal plants of only 130–140 species out of the 1200–1300 native plant species found in the continent [71]. The importance of medicinal plants is presented in Fig. 1.

2.1.1 Health Purposes

Medicinal plants are plants that are used in the treatment and prevention of various health issues and are not typically believed to be dangerous to humans [72]. These medicinal plants may be either "wild plant species," which grow on their own in self-sustaining populations in ecosystems that may be natural or seminatural and can exist without direct human intervention, or "domesticated plant species," which can be as a result of the intervention of humans such as improved breeding and selection or management [73]. Medicinal plants are utilized as raw materials when active ingredients of medicinal plants are extracted, also pure ingredients (e.g., alkaloids like quinine and quinidine from cinchona bark, emetine from ipecacuanha root, glycosides from digitalis leaves, and sennosides from senna leaves) for synthetic vitamins or steroids, as well as natural preparations and indigenous medicines. Natural raw materials are provided by medicinal plants for the majority of traditional oral and nonoral drugs [74]. Many species of plants have several medical purposes, and probably there is rarely any plant known to have several medicinal uses [75]. It is also claimed that the majority of medications used in the pharmaceutical business are obtained from one or more products from plants, with different plant components having varied functions when used in the treatment of maladies [75]. The core of the pharmaceutical sector is perhaps best described as medicinal plants.

According to WHO [56], about 30% of pharmaceuticals sold in the world today contain compounds that were gotten from plant materials, with a global sales estimate from herbal products to be about 600 million USD in 2002. About 80%

of the entire population in developing countries relies majorly on pharmaceuticals that are produced from plants for their medical and health needs. Humans have traditionally employed medicinal plants to heal and treat ailments [16, 76]. Human cultures' evolution has heavily relied on the use of biodiversity, with plant species, particularly those with medicinal characteristics, being critical for human existence [15]. It occurs in several ways throughout the world and may be traced back to ancient history, with the oldest written records of herbal remedies found in India, China, Greece, Rome, Syria, and Egypt dating back approximately 5000 years. It was estimated in 2010 that the international trade of medicinal plants and products was USD 60 billion, and expected by 2050 to reach a total estimate of USD 5 trillion.

2.1.2 Revenue Generation

Medicinal plant production can be utilized as a technique to generate money, protect biodiversity, and promote local economic growth while preserving forests [77]. In low-income countries, there is a vital and strategic relationship between the values of medicinal plants accrues, as medicines and their production are very critical and essential in maintaining a healthy human population [17, 78, 79]. This relationship also has the potential to drive and sustain the economy where it is cultivated and marketed. Pharmaceuticals derived from plants are projected to be produced commercially on a large scale, and the approach of biotechnology will drive its production. This is due to its advantages in terms of the scale of production and economic growth, the safety of the product, easy storage and distribution network, and an opportunity to supply pharmaceuticals at a low cost to developing countries due to their purchasing power which may not be matched by any commercial chain system. Medicinal plants can contribute significantly to the security of livelihood, health care that is cheap and affordable, and economic wellbeing of the populace, making them the most valued non-timber forest products.

2.1.3 Novel Medications

Medicinal plants are a valuable source of novel medications all around the world [80, 81]. Over three-quarters of the medications used worldwide were plant derived and were discovered after serious leads from indigenous medicine [82]. Globally, the market value of medicinal plants and their products is projected to be more than $100 billion per year [83]. Nigeria is a developing country, and medicinal plants are commonly used for various treatments [84, 85]. Developing countries have valuable resources such as medicinal plants; this makes them very wealthy as they have cheap sources of raw materials for the production of medicines sold at high prices [55, 86–88]. Despite being tiny individual contributors, these medicinal plants contributed to the global trade of the country in 2006 by surpassing USD 60 billion [89]. Europe has been reported to import over USD 1 billion in value of medicinal and aromatic plants from Asia and Africa [67, 90, 91]. This trade is expected to grow greatly by the year 2050 since herbal treatments are becoming increasingly popular [92, 93]. Despite accounting for a lesser proportion of agricultural output, these therapeutic plants have the highest value in terms of weight in any traded plant. These are the pharmaceutical crops of high value, which have a great potential for their countries based on agricultural techniques which contribute significantly to the economy of a region [94]. Despite accounting for a lesser proportion of agricultural output, the value from therapeutic plants is highest in terms of weight when compared with any other plant that is traded.

2.1.4 Health of Native Communities

Medicinal plants that are endemic to a specific area serve an important role in maintaining and sustaining the health and wellbeing of native inhabitants. They are also posed to provide economic returns for the localities. As a result, they offer a living for a huge number of people in the area. Since a large percentage of plants are being sourced from forests in an unsustainable manner, the pressure on these natural resources has increased. Thus, the cultivation of desired medicinal plant species can be subjected to provide an alternative source of income for farmers in such a locality. People who earn a living by selling therapeutic plants, which they either cultivate or gather, benefit from medicinal plants [95–97]. Due to the ever-increasing need for medicinal herbs, various Asian countries have undertaken large-scale cultivation of specific species.

2.1.5 Subsistence Economies

Medicinal plants also play an essential role in rural people's subsistence economies, particularly for women, in an environmentally friendly way while preserving the biodiversity of natural medicinal plant products [62]. Traditionally, the poor, particularly women, usually source, collect, and dry the wild medicinal plants before transporting them to market. Based on this, the production and processing of medicinal plants in a systematic manner provide promising new revenue and opportunities for employment in others to improve the rural poor's livelihoods in an environmentally sustainable manner. These medicinal plant uses have the potential to expand the number of rural jobs significantly. The growing and management of plants with medicinal attributes are easily associated with the employment of women in rural areas [62, 64]. Women are typically recognized for successfully administering the duties required since activities connected to medicinal plant production match women's everyday necessities and work schedules. Women are involved in the entire production process, from gathering raw materials to drying and shipping them to the market. They also receive instruction from the natural drug sector to carry out the jobs. Thus, medicinal plants provide a source of livelihood in rural areas and aid in meeting basic health care needs [98]. Medicinal plants have played an essential role in the health and economy of rural villages since ancient times; rural settlements are located outside of economic development zones and generally remain in a condition of poverty, in some cases acute poverty. This circumstance forces individuals to rely on local resources for survival, such as food, medication, clothing, footwear, and shelter [63, 98, 99].

3 The Concept of Herbal Medicine Value Chain

The word value chain simply refers to a connecting line of different aspects of business activities in the creation of a product or service, from the point of purchasing raw materials through to transportation to the point of delivery to the market or consumers. The chain flow was described as a flow of activities that are mostly needed to create a finished product from an initial raw material such as field crops [100]. For most products, the process of the value chain has five major activities, which include inbound operations, operations, outbound logistics, sales and marketing, service, and four minor activities, which are procurement and purchasing, human resource management, technological development, and company infrastructure. The concept of the value chain was first described in a book titled *Competitive Advantage: Creating and Sustaining Superior Performance* by Professor Michael Porter, who at the time was at Harvard Business School in 1985. The analysis of the value chain, therefore, is done when a business or a company identifies the major, minor, and subactivities and goes further to evaluate the efficiency of each of those activities. An important element that should be taken into cognizance while discussing the value chain has different factors involved in the production process that are likely going to have different degrees of power, which may increase or decrease and would be a function of their income level [101].

Value chain analysis focuses on two major aspects. The first aspect is to know how several types of value chains take advantage of competition by altering the way a particular product is being processed and sold [101]. Also, value chain analysis is being deployed as a device for understanding the socioeconomic benefits, demerits, and dangers involved for the several members of the chain. Herbal medicine value chains simply refer to the various stages involved in the production, processing, distribution, and marketing of herbal medicines. It starts from the cultivation of the herbs used in preparing a medicine up to the final sale of the medicine to the end consumer. A value chain typically includes all the actors that are involved in the process, such as the farmers that are actively involved in cultivation, processors, manufacturers, distributors, wholesalers, and retailers. In herbal medicine, the value chain may involve the collection of wild herbs, the cultivation of medicinal plants, the drying and processing of the raw materials, the extraction of active ingredients that does the healing, the formulation and packaging of the final product, and the distribution and marketing of the product to customers [102]. Value chains play a critical role in determining the quality, safety, and efficacy of herbal medicines. By ensuring that all stages in the value chain process are properly managed, from the sourcing of raw materials to the marketing of the final product, it is possible to produce high-quality herbal medicines that meet the needs of consumers while also supporting the livelihoods of those involved in the value chain. It is essential to have a good understanding of the internal and external linkages among the manufacturing, processing, and marketing network; knowledge of this will give a clear view of why there is variation in the value of herbal medicines in various markets [101].

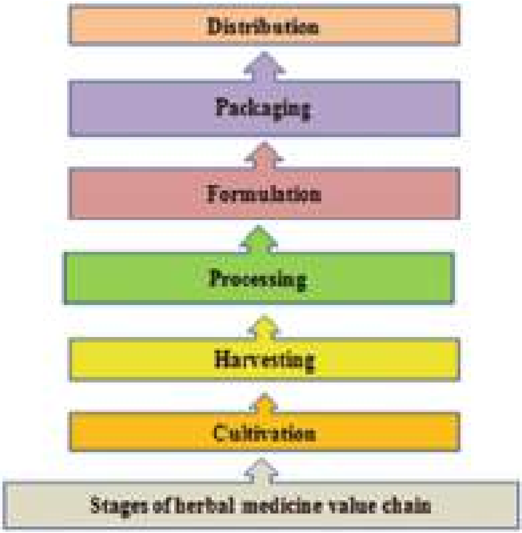

Fig. 2 Stages of herbal medicine value chain

3.1 Stages of Value Chain

The value chain of medicinal plants involves the production, processing, and distribution of plants or plant-derived products that are used for medicinal purposes. The chain in medicinal plants is a complex process that requires careful attention to detail at every stage to ensure that the final product is safe, effective, and of high quality. Figure 2 presents the flow stages of the herbal medicine value chain.

- **Cultivation:** The first stage involves the cultivation of plants deemed to have medicinal benefits. This can be done through farming, wild harvesting, or by growing plants in a greenhouse. Factors such as soil type, climate, and water availability can influence the quality and yield of the plants.
- **Harvesting:** Once the plants have reached maturity, they are harvested. This can be done manually or with the help of machines. It is important to harvest the plants at the right time to ensure that they have the maximum amount of active ingredients.
- **Processing:** The harvested plants are then processed to extract the active ingredients. This can involve a variety of techniques, such as drying, extraction, distillation, and fractionation. The extracted compounds are then purified and standardized to ensure consistent potency and quality.
- **Formulation:** The extracted compounds are then combined with other ingredients to create a final product, such as tablets, capsules, or liquid extracts. The formulation process can involve a range of techniques, such as blending, granulation, and compression.

- **Packaging:** Once the final product has been created, it is packaged and labeled. Packaging plays a key role in preserving the potency and stability of the good.
- **Distribution:** These involve the distribution of the product to retailers, wholesalers, or directly to consumers. Distribution can involve a range of channels, such as online sales, specialty stores, pharmacies, and health care providers.

3.1.1 Small/Medium-Scale Value Chain

Small- or medium-scale value chain involves the collection of primary products with a regional distribution where the healer is often also the retailer. These value chains rely on networks that are small and local or direct (one-on-one) relationships to secure the material they are processing or prescribing [101]. This has impacts on the sustainability and availability of the plants used as products. This type of value chain could have effects on the quality of the product, the benefits that are derived from it economically, the potential costs to the final consumer/patient, and it could also impact how quality can be monitored and the economic value that it generates. It was reported that in Ghana, most of the people selling herbal medicines were just full-time traders who had no idea about the source of the plant material because they did not gather the herbs themselves but just bought them from wholesalers [103]. This poses a big issue as if these retailers are unaware of the source of the plant material, they would be unaware of the compositions when it has been adulterated, and the general quality of the plant. It is very imperative to find ways of integrating the various elements of value chains. In Tanzania, the chain in value of herbal medicine consists of five actors; the harvesters who collect the plant materials; the wholesalers who process these plant materials by drying, milling, and packaging in bulk; the formulators who mix the different medicinal plants in different proportions to create a ready-to-consume product targeted at different diseases; distributors who are also sometimes retailers and healers; and then the final consumers/patients who consume these herbal medicines. Understanding this value chain is important to guide investments in the manufacture of herbal medicine [104]. In Ghana, some small- and medium-scale retailers have tried to formalize their products by using some modern techniques like bottling, but there are still the challenges of competing with foreign and imported brands in the market, which most times seem to be preferred by the consumers/patients [103].

3.1.2 The National Market Value Chain

This value chain involves the grower, collector, primary, middle manor processor, secondary middleman, retailer, and then the consumer/patient (Fig. 3). This a more complex value chain involving middlemen who serve as bridges between the producers and the retailers. They buy the plant materials in bulk from different farmers, process them, and then sell them to the retailers or consumers directly [105]. At this level, there are greater risks and more challenges to overcome as quality, purity, authenticity, and minimal level of contamination are all factors to be considered. Here only small amounts of the products are manufactured because of the rigorous pharmaceutical quality control measures put in place. The players in this chain,

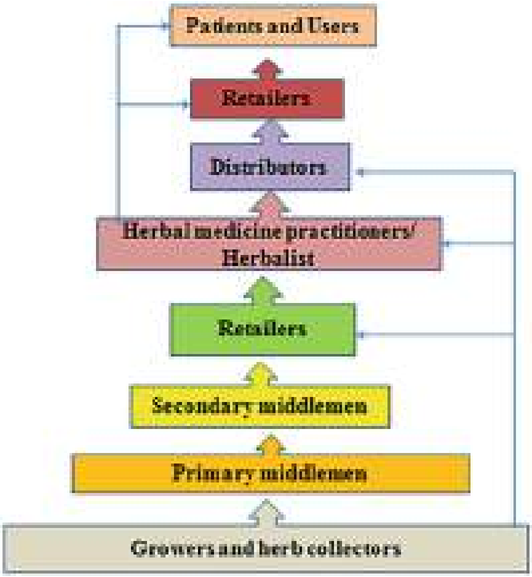

Fig. 3 National value chain of herbal medicine in many countries

especially the middlemen, have goals of scaling up the business and, therefore, will be ready to comply with regulatory institutions like the Food and Drug Administration (FDA) to pass mandatory tests and consequently secure a larger market [106]. This value chain is driven by innovations and has adopted a variety of modern equipment to increase production and guarantee quality. For example, instead of boiling the herbs to release active ingredients, alcohol may be used to extract the active ingredients [107]. Semiautomated filling machines, scanners, mixing machines, tube filling machines, and labeling machines are some of the new innovative technologies being used by the players in this value chain. The players in this chain strive to produce herbal products like tablets, pills, creams, capsules, and bottled mixtures with added preservatives to ensure a longer shelf life. This is so they can compete in the national market with other manufacturers but also with foreign herbal products [105, 107].

3.1.3 The International/Industrial Value Chain

This value chain consists of the grower, collector, middlemen/processor, exporter, consumer, country importer/distributor, retailer or practitioner, and the final consumer/patient (Fig. 4). This is a very complex value chain and involves more steps and more middlemen. Sometimes it is all controlled by a huge pharmaceutical company that controls all the different sectors till the final products and then even sales, advertising, and marketing [101]. This type of value chain has major impacts on cultural and ecological factors, as good practices are essential for this chain to work. Here the producers or retailers have little to no control over what happens with

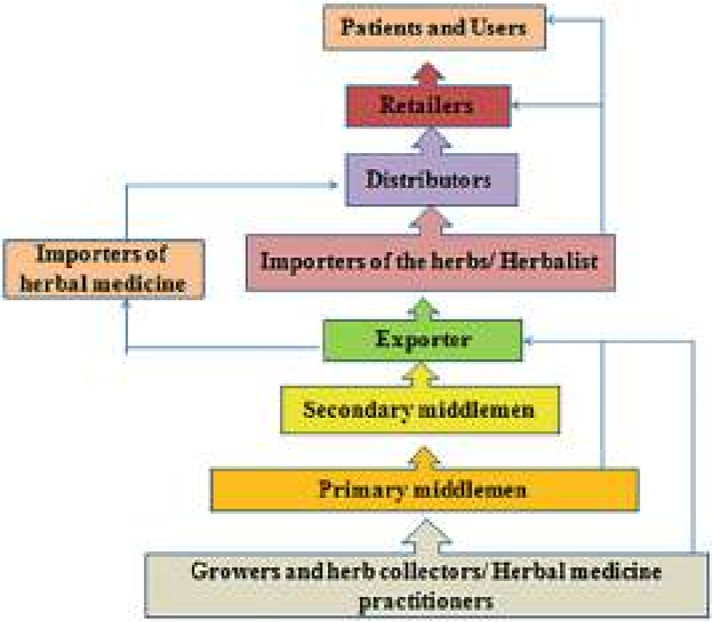

Fig. 4 International value chain of herbal medicine in many countries

the final product. Since products are being exported to other countries, lots of regulation and sophistication are required with an emphasis on commercialization, expanding the market reach in different countries [107]. The exportation of herbal products from India has increased from 69 million USD in 2005 to 128 million USD in 2009 [108]. Some Chinese farmers are now beginning to form a collaboration with sourcing pharmaceutical companies to gain access to a market that is more lucrative, thus changing the value chain. This approach can ensure the farmers get an agreed price for their products which will not be affected by conditions [105].

3.2 Value Chains of Herbal Medicines: Evidence

There is a significant amount of evidence to support the value chains of medicinal plants (Fig. 5). Some of the key findings from research studies and reports include:

- **Economic value**: Medicinal plant value chains can provide significant economic benefits to both producers and consumers. A study published in the *Journal of Ethnopharmacology* found that the global trade in medicinal plants is worth an estimated $60 billion annually.
- **Job creation**: Medicinal plant value chains can create employment opportunities, particularly in rural areas where other job opportunities may be limited.

Fig. 5 Values of herbal medicine

A report from the International Trade Center found that the medicinal plant sector is a significant source of employment in many developing countries.

- **Sustainable sourcing**: Medicinal plant value chains can be designed to promote sustainable sourcing practices that protect plant biodiversity and support conservation efforts. A report from the Food and Agriculture Organization of the United Nations found that sustainable harvesting practices can help to ensure the long-term viability of medicinal plant resources.
- **Quality control**: Medicinal plant value chains can include quality control measures to ensure that products are safe and effective. This can involve testing for contaminants, verifying the identity and potency of active ingredients, and ensuring compliance with regulatory standards.
- **Access to health care**: Medicinal plant value chains can help to improve access to health care, particularly in underserved communities. A study published in the *Journal of Public Health and Epidemiology* found that medicinal plants are widely used as a source of health care in many developing countries.

The evidence suggests that medicinal plant value chains can provide significant economic, social, and environmental benefits. However, it is important to ensure that these value chains are designed and implemented in a way that promotes sustainability, quality, and equitable access to health care. There have only been limited studies on medicinal plants' value chains. Researchers have reported that they are ethnographically based on value chains within the South American region [109, 110]. Also, it was reported that there are ecological pressures on plant species that have medicinal powers and rapid depletion in abundance and composition as a result of overexploitation [111]. Developing countries, an example of which is Nepal, rely majorly on the harvesting and marketing of plants with medicinal values which are sourced from the wild as their main source of income. Therefore, their research pointed out a key factor which was to enforce restrictions on the indiscriminate harvesting of medicinal plants and also advocating for the large-scale cultivation of these plants.

3.3 What Infers the Need for Herbal Medicine Value Chain Analysis?

Herbal medicine value chain analysis is a useful tool for evaluating and understanding the entire process involved in the production, distribution, and consumption of herbal medicines. Herbal medicine value chain analysis can help stakeholders in the industry to better understand the entire process of production, distribution, and consumption of herbal medicines and to identify areas for improvement and growth. The need for this analysis arises due to the following reasons:

- **Identifying opportunities for value addition:** Value chain analysis helps to identify opportunities for adding value to herbal medicines. It can help to identify areas where improvements can be made in production, packaging, transportation, and marketing, thereby increasing the value of the final product.
- **Improving efficiency:** Value chain analysis can help to identify inefficiencies in the production and distribution of herbal medicines, such as bottlenecks in the supply chain or areas where productivity can be improved. By addressing these inefficiencies, the overall efficiency of the value chain can be improved, leading to cost savings and increased profitability.
- **Identifying potential risks:** Value chain analysis can help to identify potential risks in the herbal medicine value chain, such as regulatory or market risks. This can help to mitigate these risks and ensure the sustainability of the industry.
- **Enhancing competitiveness:** Value chain analysis can also help herbal medicine producers and distributors identify areas where they can improve their competitiveness. By understanding their strengths and weaknesses relative to their competitors, they can develop strategies to improve their market position.

3.4 Benefits of Herbal Medicine Value Chains

The value chain of herbal medicine can provide a range of benefits, from economic growth and job creation to improved access to health care and the preservation of traditional knowledge. It is important to ensure that these value chains are designed and implemented in a way that promotes sustainability, quality, and equitable access to health care. There are many potential benefits associated with the value chains of herbal medicines. Here are some of the key benefits:

- **Economic benefits:** The herbal medicine value chain can contribute to economic growth and job creation. The production, processing, and distribution of herbal medicines can create employment opportunities in both rural and urban areas. In addition, the herbal medicine industry can generate revenue through exports.

- **Sustainability:** The herbal medicine value chain can promote sustainable practices such as the conservation of medicinal plant species and the use of organic farming methods. This can help to ensure that herbal medicines are produced in an environmentally sustainable way.
- **Cultural heritage:** The value chain of herbal medicine can help to preserve and promote traditional knowledge and cultural practices. Many herbal medicines have been used for centuries by indigenous communities, and the herbal medicine value chain can help to ensure that this knowledge is not lost.
- **Health benefits:** Herbal medicines can provide a range of health benefits and can be used to treat a variety of conditions. The value chain of herbal medicine can help to ensure that these products are of high quality and are effective in treating specific health conditions.

3.5 How to Conduct a Value Chain Analysis

Conducting a herbal medicine value chain analysis can help identify opportunities for improvement and support the development of a sustainable, high-quality herbal medicine industry. It is important to involve all important stakeholders in the analysis and to develop an action plan that is feasible and realistic. The analysis involves a systematic assessment of the various stages involved in the production, processing, distribution, and consumption of herbal medicines (Fig. 6). Here are some of the key steps involved in conducting a value chain analysis for herbal medicines:

Fig. 6 Steps in conducting value chain analysis

- **Identify the key stakeholders:** The first step is to identify the key stakeholders involved in the herbal medicine value chain. This can include producers, processors, distributors, retailers, regulators, and consumers.
- **Map the value chain:** The next step is to draw out a plan indicating the various stages of the value chain, from the production of medicinal plants to the distribution and consumption of herbal medicines. This can be done using a flowchart or other visual representation.
- **Assess the performance of each stage:** Once the value chain has been mapped out, the next step is to assess the performance of each stage. This can involve analyzing factors such as efficiency, quality, sustainability, and profitability.
- **Identify opportunities for improvement:** Based on the assessment of each stage, opportunities for improvement can be identified. This might involve improving production techniques, enhancing quality control measures, or developing new distribution channels.
- **Develop an action plan:** Finally, an action plan can be developed to implement the recommended improvements. This might involve developing new partnerships, investing in new technology or infrastructure, or providing training and capacity building to stakeholders.

4 Challenges Within Herbal Medicine Value Chains

The attention paid to medicinal plants, and their value chain is not significant, as it is an area faced with diverse difficulties, most especially in the supply chain. Difficulties are experienced at every step, with a major one being exploitation by middlemen, overharvesting of herbal plants in the wild, contamination, and substandardization of herbal products and activities along the value chain, and a lack of quality control and policies of activities along the value chain [10]. Herbal medicine has been widely used in the diagnosis, prevention, and treatment of various diseases, and regulation of the medicine is a big issue. The use has created a lot of challenges relating to the safety, quality, and efficacy of the herbs. To address this, validation as well as scientific and technological standardization is required for advancement in herbal medicine [106]. The use of herbal medicine by individuals in the world today has increased, thereby making the issues that are related to their safety a crucial aspect in the value chain. Most of the adverse effects caused by herbal medicines are connected with different problems [112]. The issue of quality control is a major issue in the herbal medicine value chain and can be classified into internal and external challenges.

- **Internal challenges:** It focuses on the complexity and nonuniformity of herbal medicine ingredients which can affect the quality and distribution of herbal medicines along the value chain.
- **External challenges:** It circles contamination from microbes, toxic chemicals, pesticide residues, adulteration, and misidentification of herbal medicines, which may be peculiar to the medicine value chain. These challenges can be reduced by the implementation of rigorous good agricultural collection practices (GACP) and

good manufacturing practices (GMP) in the value chain. Modern methods and techniques in analytical and pharmaceutical strategies can be employed.

There are diverse value chains in herbal medicine with various challenges peculiar to their activities. Herbal plant cultivation could improve the livelihoods of the people who are poor and own small pieces of land [113]. To address the major challenge in the value chain, which is the issue of sustained growth of medicinal plants, a fair distribution to the primary producers must become necessary. Also, the consumers and manufacturers indirectly pay a larger proportion of the money for middlemen's value because the chain is usually weak and inherent [10]. To address this, a value chain that is integrated with only producers and processors as commercial actors and NGOs which serve as promoters can create a value chain network that is economically robust and can benefit a lot of people rather than a few [114].

4.1 Challenges in Supply Networks

The increased trade and high value of medicinal products have brought about various challenges which are concerned with the supply of the product along the value chain. The concerns have either been on addressing a specific problem as regard quality, such as poor production systems and adulteration of medicinal products, or solving a specific concern in terms of social or economic context. The supply chain can also generate concerns such as sustainable supply, responsible sourcing, and sharing of benefits. Supply has been a major issue but increased awareness has been generated since 2012 in terms of the herbal materials value chain in a globalized market [101]. The core characteristics of the supply chain sector of the herbal medicine value chain have various links, such as:

- The herbal material may be sourced from the wild or cultured and a mix of the two sourced products can be supplied.
- There may be the presence of numerous primary producers (required as a necessity).
- The role of middlemen may be required to link complex value chains with international buyers.
- The lack of knowledge and poor practices toward herbal species that are overharvested or endangered.
- There may be an upscale increase in price when the medicinal product gets to the end users from the producers.

4.2 Challenges of Quality Considerations in Herbal Medicine Value Chains

Assurance of the quality of products from herbal medicinal sources is more complex than the procedure of quality assurance of pharmaceutical products. There is high variability in the composition of natural herbal medicinal products. Therefore, the assessment of quality must be considered in terms of the diversity and the value chains from which medicinal products may originate. The safety and quality of an herbal product on a short value chain is easy to control effectively and manage.

4.2.1 Challenges of Heavy Metal Contamination

There are two main reasons why herbal products are prone to contamination by heavy metals; these are pollution and natural accumulation. In developing countries, pollution from heavy industries is a major problem, and the issue has been addressed in some countries. Although the route pollutants find their way to cultivated lands through water channels will take a long time to remediate [65]. Some plants may accumulate heavy metals naturally, e.g., cadmium can be accumulated by *Perillia* sp or *Hypericum perforatum,* and some are found in areas where the subsoil contains heavy metals, e.g., cinnabar in the formation of rocks which can result to the high occurrence of mercury in some species. These problems can be reduced by careful identification and selection of sites for cultivation or apt monitoring and control in wild herbal plant species collection. There is less need for the use of pesticides in the short supply value chain, but due to expectations by customers and global supply a high level of pesticide usage is required to produce increased yield at a reduced cost. Training and careful management of the value chain regarding pesticide use and quantities can keep the number of pesticide residues in herbal plants within the allowable limits.

4.2.2 Challenges Associated with Antimicrobial Resistance

The antimicrobial resistance in herbal medicine usually arises when bacteria and fungi which are termed germs may overpower the herbal drugs that were fashioned to attack them. This implies that the germs that were meant to be killed by the herbal drugs are still living and they continue to grow. In some cases, such resistant germs or infections are usually difficult and almost impossible to eliminate. The Centers for Disease Control and Protection (CDC) reported such resistance as a public threat and has been linked to about 5 million deaths and killed a minimum of 1.27 million people across the world [115]. More than 35,000 deaths occur in the USA based on drug resistance. The extent of danger is not only observed when bacteria or fungi develop resistance to herbal drugs but when it is resistant to just one is a serious issue. For instance, some ailments/infections may require further treatments after herbal medications can cause serious side effects to patients and prolong recovery periods. With all of these events, it can be said that the issue of antimicrobial resistance can affect people at any life stage, therefore, making it a major health concern for the public.

The World Health Organization also reported antimicrobial resistance as one of humanity's major public threats [116], which is projected to claim over 10 million lives by 2050 and an economic cost of US $100 trillion globally [117]. The presence of resistant bacteria and fungi is becoming resistant to present antibiotics, and with few products in the pipeline, it is important to urgently look into the development of new strains by taking a cue from herbal medicine. The issues of resistance are very complicated and is multifaceted and may contain the following variables as reported [118, 119]:

- Lack of hygiene in hospitals, thereby increasing bacteria resistance
- The overuse of antibiotics in agricultural activities
- The spread of resistant varieties through international travels
- Excessive use by humans
- Lack of diagnosis on the appropriate antibiotic to use

Apart from the health sector, resistance can also occur in the food industry. Aflatoxins produced by *Aspergillus* spp. are a major mycotoxin in the food industry that is carcinogenic and highly toxic [120]. The contamination varies with the type of products; it is high in wheat, maize, nuts, and barley [121, 122]. The risks of contamination can be reduced by storage, processing, or transportation as the fungi grows when the conditions are right for it to thrive.

4.2.3 Challenges of Sustainable Sourcing of Herbal Products

There are many problems regarding the sustainability of herbal products and the value chain, one of which caused the withdrawal of some services in the markets [123]. Based on this, there are changes in the supply chain of goods, an increase in awareness, and increased demand by customers for herbal products. The reports of the Ethical Consumer Markets 2017 stated that the sustainability certification of herbal materials increased consumer spending [124]. The blockchain approach can go a long way in addressing the issue of sustainability as it can aid the collection and processing of herbal materials, thereby providing information that is the baseline for the products. Such information will be readily available for all the actors along the value chain. In a case where there is already a developed sustainable production system, the blockchain system can assist in certifying the production systems. Overexploitation of herbal materials can be prevented by tracking and information about the initial processing methods, thereby producing a better system of production.

4.2.4 Challenges of Intellectual Property

Intellectual property rights are an area of contention in herbal products and their value chain, and it is essential to abide by international agreements and national laws to forestall the development of herbal products rationally. Herbal medicines are mostly used in traditional settings in most developing countries and have become often adapted for use in developed countries, thereby creating a high commercial value for these products. These has created avenues for diverse conflicts in terms of patenting without the consent of or compensation to the original custodian of these herbal medicines. Originally, it is believed that the rights to this indigenous knowledge are bestowed on the indigenous people because they are close to the biological resources, have the knowledge, and know the appropriate items to use at a particular time. They are directly linked with the biodiversity conservation of these herbal plant species. In the present state, dilemmas, challenges, and several ethical questions have arisen based on the operations of the indigenous people toward conservation. Timmermans [125] reported that ways by which modifications can be made and new forms of ownership based on intellectual property that can settle the rift between indigenous people and modern science should be created. The author continued that the protection of herbal medicine intellectual property has diverse objectives and proposed strategies may affect one another as well as affect the goals and prioritization of proposed objectives. It was concluded that policies should address the multicomplexed questions and issues and try to balance them by developing a range of solutions to address each question and issue. Similarly, Mokgobi [126] opined that the integration of the traditional healing system and Western biomedicine can go a long way in addressing these challenges. As in South Africa, the number of traditional practitioners are huge and the government also supported the integration of the two systems of health care.

5 Recent Development in Herbal Medicine Value Chains and the Concept of Blockchain

There are various opportunities arising from the medicine value chains using a transdisciplinary approach [101]. A more recent approach that involves blockchain systems may be used to address some issues arising from the dynamic socioeconomic value chain frameworks such as the limitations in the number of middlemen in the value chain. This approach is quite useful in updated information dissemination and activities across the value chain. It is quite useful in supply chains with many stakeholders, and the benefits that accrue to producers, production channels, materials sourcing, and quality final herbal products can be achieved. The knowledge of an herbal product along the value chain is key in the exchange of goods and information, as well as information relating to the composition of the product, type, source, quality, and other information of importance about the product, which are stored in ledgers.

The concept of blockchain replaces the analog ledger approach, and it is a system that is built on decentralized data storage by several users, each forming a network node [124]. Information are usually stored in blocks, and all form a chain on the network which is only modifiable one block at a time. The technology is a very transparent database that is advanced and presents information sharing in a very transparent form within a business setup. It was said that there are enormous opportunities for using blockchain technology in food industries and herbal medicine distribution [126, 127]. This approach can be vital in complex transaction networks that lack trust in their value chains. The blockchain will provide a safe interphase for interaction between various actors along the value chain without necessarily building individual trust. The trust is usually in the blockchain system and optimized for better delivery [128, 129]. The negotiations can be validated using smart contracts, which are fused into the blockchain framework. These contracts are effective ways of validating contracts in the digital currency world [128]. When conditions on the contracts are met, payments will be automatically released to the parties, ensuring a fraud-free transaction.

The benefits of the use of blockchain technology in the herbal medicine value chain are:

- It will increase trust and reliability in parties or buyers that do not trust each other.
- It will remove third-party involvement, increase benefits economically, and decrease costs incurred in transportation and logistics.
- All records and transactions are saved and can be recalled for transparency and promotion of good practices.
- Small-scale producers can receive immediate benefits from commercialization.

6 Conclusion

The use of medicinal plants has become a popular activity all over the world due to their unique advantages and medicinal value. These medicinal herbs are becoming more and more important on a global scale as a result of their growing traditional use and cultural acceptance. They are also well recognized and have minimal side effects. These medicinal plants used for herbal medicine can be made more well known and used to boost the economies of low-income nations and provide jobs for their citizens. The majority of African nations rely heavily on the primary health care approach, hence it is crucial to integrate the use of medicinal plants into every aspect of primary health care in these nations. The rural population of nations needs high-quality raw materials for the development of drugs from medicinal plants to meet their fundamental health care demands. By including them in the processing and collecting of medicinal plants, the vast majority of people living in rural regions can also be given employment opportunities. The popularization of medicinal plants is crucial for the preservation of traditional knowledge. The state government should take action to educate the populace about the importance of these medicinal plants. Additionally, more resources should be allocated toward enhancing health-care-based systems. This will spur the development of the concerned industry. Farmers should be provided with top-notch marketing tools. It is important to use cutting-edge marketing strategies so that farmers experience fewer challenges and earn more money.

Abstract

Chemotherapy is routinely used for the treatment of cancer. However, chemotherapy treatments, for example, 5-fluorouracil, doxorubicin, bleomycin, and cyclophosphamide, give various kinds of side effects and toxicity. To hinder the

development of carcinogenic tumours, some patients in developing countries take traditional medicine as chemoprevention, an alternative, complementary, and supportive therapy, in spite of following the standard therapy protocol. Several traditional medicines from China, India, and Egypt are known for this purpose. There are some plants used as chemopreventive agents with several formulas such as *Annona muricata*, *Curcuma longa*, *Curcuma xanthorrhiza*, *Curcuma zedoaria*, *Euphorbia abyssinica, Garcinia mangostana*, *Gynura procumbens*, *Kaempferia galanga, Morinda citrifolia*, *Moringa oleifera*, *Nigella sativa*, *Phyllanthus urinaria,* and *Zingiber officinale*. Various numbers of *Annona muricata* extracts demonstrated anticancer activity in vitro and in vivo. Acting as a p53 regulator and pro-oxidant in MCF-7 cells, and also as a fatty acid synthase inhibitor in MDA-MB-231 cells, curcumin is collected from *Curcuma longa* and *Curcuma xanthorrhiza*. Through modulation of Bcl-2, p53, and PARP-1 protein levels, xanthorrhizol from *Curcuma xanthorrhiza* has pro-apoptotic activity. Curcumenone, curcumenol, and curdion, which are from *Curcuma zedoaria,* display pro-apoptotic activity in various cancer-induced cell lines and mouse models. The apoptotic effect induced by corilagin is mediated by extrinsic and mitochondrial pathways, whereas the apoptotic effect induced by geraniin is mediated by ROS-mediated stimulation, both in MCF-7 cells. However, the pro-apoptotic effects of corilagin and geraniin from *Phyllanthus urinaria* are distinct. *Nigella sativa* extract contains some active ingredients, including thymoquinone, which can extend the time of DMBA-induced tumour formation in mice. Active compounds from *Kaempferia galanga* can inhibit carcinogenesis by inhibiting proliferation of cell lines and also angiogenesis. Based on the above data, the use of chemoprevention in inhibiting carcinogenesis has a very good prospect for further development of sustainable food sources.

1 Introduction

To date about 88% of all countries in the world use traditional medicine, such as herbal medicine, acupuncture, yoga, indigenous therapy, and others. Even 170 WHO member countries reported the use of traditional medicine; now it has become an important resource for health for centuries in communities throughout the world and is still a mainstay for some people who have uneven access to conventional treatment. Sociocultural practices and the existence of biodiversity from traditional medicine are invaluable resources for sustainable and diverse sustainable development for curing the diseases.

Defined as the unusual growth of cells in body tissue, cancer is a frequent condition in which destructive change occurs without apparent cause [1]. Factors such as sedentary lifestyle, poor eating habits, smoking, etc., can contribute to the growth of tumours [2]. According to the WHO, the number of cancer patients in the world increases by about seven million people every year, two-thirds of them in the developing countries. Chemotherapy, radiation exposure, and complicated medical procedures are required during the costly and side-effect-filled treatment of cancer.

Despite using chemical drugs to treat cancer, another way to cure or prevent cancer is by using phytotherapeutic agents or traditional medicine consisting of one active ingredient or mixture complexes of various origins of plant parts. Those herbs are commonly grown and known in some countries, like Asia and Africa. For example, over the last decade, the use of herbal medicines has increased in Indonesia based on the fact that Indonesia has many biodiversity contents of natural substances that can be utilized.

The aim and goal of this chapter are to investigate various traditional herbs from China, India, Indonesia, and other Asian countries that are used as chemoprevention practices. It also will go into more specifically about the active compounds of each herbal medicine, in vitro and in vivo assay, and chemoprevention mechanism research on some herbal medicine. The data were obtained by exploring the keywords (chemoprevention, herbal medicine, antioxidant, anti-inflammatory, apoptosis, angiogenesis, anticancer) in Google Scholar, PubMed, and other Internet sources.

2 Chemopreventive Practices in Traditional Medicines

Chemoprevention is the use of certain compounds, whether in the form of synthetic drugs or natural ingredients, to help reduce the risk of getting cancer, organ complications, or prevent the occurrence of these diseases. It can also be used for inhibition delay or to reveal carcinogenesis before invasion. Agents that can be used are classified into four categories, including hormonal, medications, diet-related agents, and vaccines. Tamoxifen and raloxifene are used in averting several types of breast cancer in women who are at high risk of developing the disease, for instance [3].

Several traditional medicines from Indonesia, China, India, and Egypt were recognized to be used for this purpose as chemopreventive agents with several formulas, such as *Curcuma longa*, *Annona muricata*, *Curcuma xanthorrhiza*, *Phyllanthus urinaria*, *Curcuma zedoaria*, *Gynura procumbens*, *Morinda citrifolia*, *Garcinia mangostana, Nigella sativa*, *Zingiber officinale*, *Moringa oleifera*, *Kaempferia galanga,* and *Euphorbia abyssinica.*

2.1 *Annona muricata*

2.1.1 Taxonomy

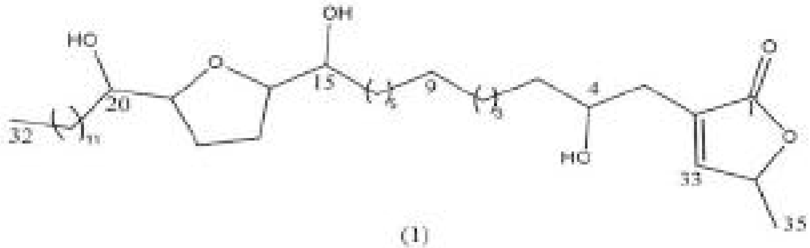
Native to South and North America, *Annona muricata,* or soursop, is a plant in the family Annonaceae. As shown in Fig. 1 [4, 5], it has an open circular canopy with large, glossy, dark, and green leaves characteristically.

The tree produces large, individual yellow flowers on woody stalks, and its edible fruits are able to weight above 4 kg. Each fruit segment contains a single, oval, smooth, hard, black seed. The leathery skin of the fruit is covered in short spines [6].

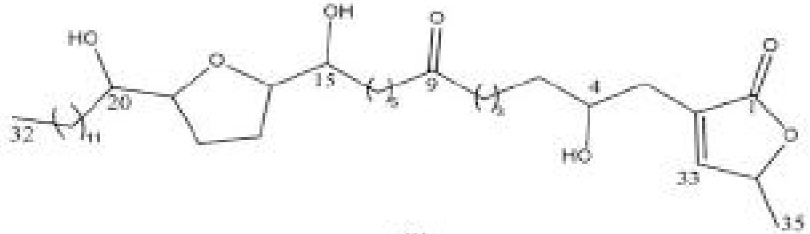
2.1.2 Phytochemistry

A. muricata contains numerous compounds as well as megastigmanes (MGs), alkaloids (ALKs), flavonol triglycerides (FTGs), cyclopeptides (CPs), essential oils, and phenolics (PLs). This plant also contains annonaceous acetogenin compounds (AGEs). *A. muricata* fruit contains nutrients and essential elements for humans because it contains elements such as Ca, Cu, Fe, K, Na, and Mg [4]. Additionally, as illustrated

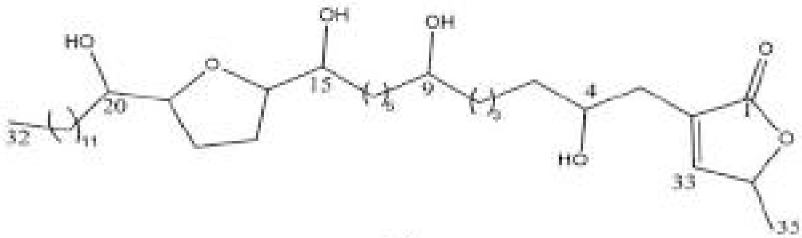
Fig. 1 The fruits of *Annona muricata* L.



(1)



(2)



(3)

Fig. 2 Acetogenins from *Annona muricata* seeds and fruits: murisolin (1), annoreticuin-9-one (2), *cis*-annoreticuin (3), and sabadelin (4). (Ragasa et al. [7])

in Fig. 2, Ragasa & Shen [7] reported compounds such as acetogenins: murisolin (1), annoreticuin-9-one (2), *cis*-annoreticuin (3), and sabadelin (4).

Annona muricata (soursop) is a plant that contains several isoquinoline alkaloids, including anomuricine, anomurine, atherosperminine, coclaurine, coreximine, reticuline, and stepharine in its leaves, root, and stem barks. Additionally, annomuricatin is present in the plant's seeds. Besides, the fresh fruit pulp of *A. muricata* also contains the essential oil which consists of ethyl 2-hexenoate (8.6%), methyl 2-butanoate (2.4%), methyl 2-hexenoate (23.9%), methyl 2-octanoate (5.4%), α-terpineol (2.8%), β-caryophyllene (12.7%), 1,8-cineole (9.9%), linalool (7.8%), linalyl propionate (2.2%), and calarene (2.2%). The leaves of *Annona muricata* also contain annohexocin and mono-THF annonaceous acetogenin that display substantial repressive effects against six human cancer cell lines [8].

2.1.3 Usage as Chemoprevention

A. muricata has been the subject of numerous anticancer studies, including both in vitro and in vivo studies. While investigating a particular case, an elderly woman diagnosed with metastatic breast cancer consumed boiled *A. muricata* leaves along with Xeloda, resulting in the stabilization of the disease [9]. It is substantial in preventing cancer and tumour growth that was observed in *A. muricata* leaves that have been utilized in the development of tablet formulations containing the ethyl acetate-soluble fraction of the leaves. The fraction of AGEs can be used in adjuvant therapy [10]. On the other hand, as shown in Table 1, the primary mechanism of action has been investigated in several studies.

The effects of an aqueous extract made from the leaves of *A. muricata* on the benign prostatic hyperplasia (BPH-1) cell line and the prostates of rats were the subject of recent in vitro and in vivo experiments. The study showed that BPH-1 cell activity was reduced by the treatment. Following treatment for 72 h, the mRNA levels of Bax were upregulated and Bcl-2 were downregulated, along with the IC50 value of 1.36 mg/mL. Moreover, 2 months of treatment with the extract (at doses of 300 and 30 mg/mL) resulted in a reduction in the size of prostates of rats, likely due to apoptosis induction [11].

Promising antitumour effects of *A. muricata* also revealed in vivo investigation using mice as a subject with 7,12-dimethylbenzene anthracene (DMBA)-induced cell proliferation in the breast tissues. According to the investigation, *A. muricata* leaves administered orally were effective in preventing the damage of DNA induced by DMBA, which may help prevent the growth of breast carcinogenesis [12]. Furthermore, even at a reduced dosage of 30 mg/kg, the leaves suppressed the promotion and initiation stages of skin papillomagenesis in mice induced by DMBA and croton oil, respectively [13].

Annona muricata Linn. leaves have been shown to decrease the expression of the p53 protein in cancer patients infected with HPV, resulting in increased apoptosis. When a virus infected a cell, there is a stress increment and the p53 protein expression rises as a response. However, a reduction in the p53 protein expression can disturb the cell's ability to undergo apoptosis. Being the main role in apoptosis regulation, proteins such as p53, Bcl-2, and caspase-3 act as inhibitors of cancer. A decrease in apoptotic cells can cause an imbalance between apoptosis and cell proliferation, triggering the growth of cancer. Mutations in the p53 gene are responsible for the loss of p53 function in 50% of human cancer cells. The E6 protein of

Table 1 Anticancer studies of *A. muricata*

Plant part	Subject of study	Chemoprevention mechanism
Ethyl acetate extract of the leaves	Lung A549 cancer cells	Mitochondrial-mediated apoptosis, cell cycle arrest at G1 phase
Ethyl acetate extract of the leaves	Colon HT-29 and HCT-116 cancer cells	Mitochondrial-mediated apoptosis, cell cycle arrest at G1 phase, suppression of migration and invasion
Water extract of the leaves	Rat's prostate	Reduction of prostate size
Ethanolic extract of the leaves	Breast tissues of mice	Prevention of DMBA-induced DNA damage
Ethanolic extract of the leaves	DMBA/croton oil-induced mice skin papillomagenesis	Suppression of tumour initiation and promotion
Ethanolic extract of the leaves	DMH-induced colon cancer	Reduction of ACF formation
Ethanolic extract of the leaves	K562 chronic myeloid leukaemia cells	Induction of apoptosis
Leaves boiled in water	Metastatic breast cancer	Stabilization of disease

Ethyl acetate extract of the leaves	Colon HT-29 cancer cells the leaves	Bioassay-guided isolation of annomuricin E and its apoptosis-inducing effect

Mugadhamtousi et al. [4]

HPV-16 and 18 can inactivate the p53 gene product through the ubiquitin-dependent proteolytic pathway (E6AP), leading to a decrease in p53 protein levels. Restoring the function of mutated p53 could trigger mass apoptosis, effectively killing cancer cells [14].

Astuti et al. [15] showed that the ethanol extract of *A. muricata* leaves contains antiproliferative effects on WiDr cancer cells. The range of IC50 values of the extract was from 6 to 12 μg/mL (after 48 h). Another study on ethanol extract of *A. muricata* from Tawangmangu also showed antiproliferation on WiDr cancer cells with an IC50 of 450.05 μg/mL, which was much larger than the previous study due to the differences in location and quality of the leaf essence. In addition, incubation with *A. muricata* on HepG2 liver cancer cells for 24 and 48 h showed LD50 values of approximately 80 and 180 μg/mL, respectively. Entering the G0 phase of G1 is a crucial choice in cell development. Additionally, in situations where the cellular environment is insufficient to cross the restriction point, it will return to the G0 phase.

Fig. 3 *C. longa* rhizomes with yellowish to orange colour

2.2 *Curcuma longa*

2.2.1 Taxonomy

Turmeric, which is a perennial shrub in the family Zingiberaceae and also known as *Curcuma longa* Linn, originates from India as depicted in Fig. 3 [16]. The plant can grow up to a height of 3–5 feet and is now cultivated in other tropical countries such as China and Sri Lanka. The roots of the plant are highly valued and are utilized for religious, culinary, and medicinal purposes in India [17].

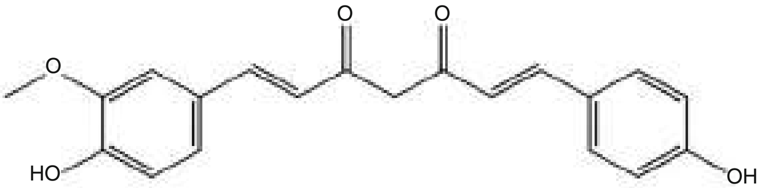
After harvesting, the turmeric rhizomes are washed and boiled in mildly alkaline water to soften them. They are then dried either in the sun or using an electric dryer. Turmeric is usually used as a colouring agent in diverse industries such as pharmacy, confectionery, and the food industry. It is also used for dyeing materials such as wool, silk, and cotton, and can be combined with other natural dyes to create a range of different shades [18].

2.2.2 Phytochemistry

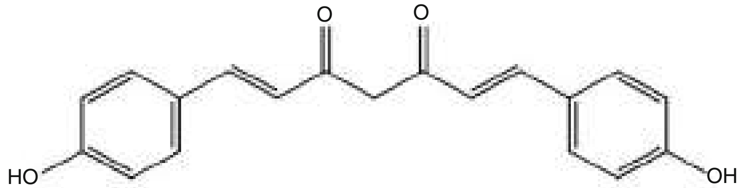
The three main chemical constituents of turmeric – curcumin (CUR), demethoxycurcumin (DMC), and bisdemethoxycurcumin (BDMC) – are illustrated in Fig. 4. These compounds, which belong to a group of chemicals called curcuminoids, make up approximately 77%, 17%, and 3% of turmeric, respectively. Each of these constituents has distinct biological activities [19–21].

Two active components that are found in turmeric are curcuminoids and volatile oil, usually found in the extraction of oleoresin from turmeric root. The essential oils in turmeric consist mostly of sesquiterpenes. Pungent scent of the spice is primarily acquired from α- and β-turmerones and aromatic turmerone (Ar-turmerone) [22]. Curcuminoids are not very soluble in water when the pH is acidic or neutral due to their chemical structure, but they are soluble in acetone, dimethyl, ethanol, methanol, and sulfoxide [21].

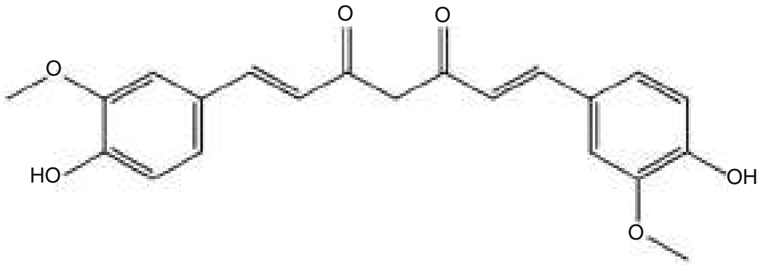
Several active compounds have been discovered in *C. longa*, including diarylheptanoids such as curcumin, demethoxycurcumin, and bisdemethoxycurcumin,



Demethoxycircumin (DMC)



Bisdemethoxycurcumin (BDMC)



Curcumin (CUR)

Fig. 4 The chemical structure of curcumin (CUR), demethoxycurcumin (DMC), and bisdemethoxycurcumin (BDMC). (Huang et al. [19])

as well as sesquiterpenoids such as α-curcumene, β-at-lantone, curcumol, diterpenoids, dehydrocurdione, phenolic acids, and polysaccharides [23, 24]. In previous investigations, some sesquiterpenoids have also been identified. In an effort to identify new biological elements present in *C. longa* and enhancing its chemical components, the rest of the fractions of the plant were further fractionated, resulting in the discovery of a new bisabolane-type sesquiterpenoid, (6S)-2-hydroxy-6-[(1′S,5′R)-(4′-methene-5′-hydroxyl-2′-cyclohexen)-2-methylheptan-4-one], and turmerone Q (1). Six known compounds, including three sesquiterpene derivatives (2–4), two diarylheptanoids (5–6), and one diphenyl alkane (7), are illustrated in Fig. 5 which were also identified [25–28].

The essential oil of *C. longa* rhizome and leaf contains several compounds, with the most abundant being α-phellandrene (9.1%), α-turmerone (24.4%), ar-turmerone

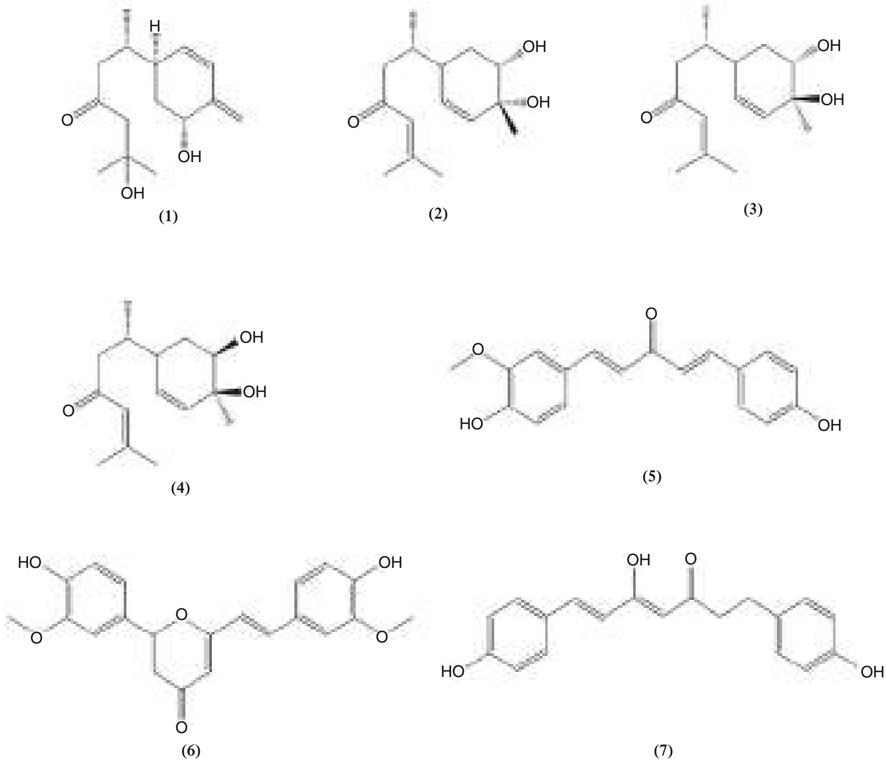


Fig. 5 Structures of compounds 1–7. (Yuan et al. [25])

(25.5%), β-sesquiphellandrene (5.1%), β-turmerone (14.0%), terpinolene (7.2%), (Z)-β-ocimene (5.5%), undecanol (7.1%), p-cymene (5.5%), α-zingiberene (4.8%), ar-curcumene (1.6%), β-caryophyllene (2.9%), and 1,8-cineole (1.3%) [29, 30].

2.2.3 Usage as Chemoprevention

C. longa possesses multiple pharmacological activities, including anti-inflammatory, antioxidant, hepatoprotective, anticarcinogenic, antidiabetic, antimicrobial, and anti-depressant effects. It has also been studied for its potential use in treating cardio-vascular disease, gastrointestinal disorders, and neurological disorders [31].

In rabbits, the consumption of turmeric powder has been shown to increase the secretion of mucin, which may help protect against irritants in the gastrointestinal tract. While turmeric exhibits both anti-ulcer and ulcerogenic properties, research has found that curcuma, a compound found in turmeric, is as effective as ranitidine in protecting the gastric mucosal layer. When administered orally, turmeric has been found to inhibit gastric acid and gastric juice secretion, as well as prevent ulcer formation, similar to the properties of ranitidine. Turmeric has also been shown to have a protective effect on the cardiovascular system by lowering the levels of cholesterol and triglyceride, lowering the susceptibility of low-density lipoprotein (LDL) to lipid peroxidation, and preventing platelet aggregation. Animal experiments suggest that the presence of turmeric extract and curcumin in turmeric can potentially reduce the occurrence of tumour formation in test animals. This research shows that turmeric might be an effective anticancer ingredient [32].

Kim et al. [33] demonstrated chemopreventive effects in an in vitro model related to hepatitis B virus (HBV). A study was conducted on HBV X protein (HBx) transgenic mice which aimed to analyse the effects of chemopreventive mechanism in vivo. The mixture of a *Curcuma longa* Linn (CLL) was concentrated with dextrose water by boiling and then lyophilized, and the resulting extracts were administered to the mice for 2–4 weeks starting at 4 weeks of age or for 3 months starting at 6 months of age. The liver tissue was analysed for histological changes and the expression of genes associated with HBx. Additionally, CLL treatment led to an increase in p-p53 expression. These findings indicate that CLL could be advantageous in preventing and postponing liver cancer by affecting the initial and later phases of liver disease. Therefore, CLL may be a potential candidate for chemopreventive agents against liver cancer [34].

In traditional Indian Ayurvedic medicine, turmeric (*Curcuma longa* L.) has long been used for a variety of medical conditions. In addition, turmeric has also been reported against DENA-induced cancer of the skin, stomach, colon, oral cavity, and liver in rats [35]. Turmeric provides a chemopreventive effect against HCC induced in Wistar rats and relatively improves biochemical parameters so that it can control and delay the initiation of carcinogenesis [36]. Curcumin's antioxidant effects, which can significantly lower the level of oxidative stress that contributes to the growth of cancer, maybe the cause of its chemopreventive properties [37].

The various levels of regulation in cellular growth and apoptosis that are targeted by curcumin to exert its anticancer effects are depicted in Fig. 6. Curcumin not only affects transcription factors, oncogenes, and signalling proteins in a vertical manner, but it also acts in different stages of carcinogenesis, starting from the initial DNA mutations to the development of tumours, their growth, and metastasis. Due to its broad and multifaceted impact on the regulatory processes of cell growth, curcumin is a promising candidate for chemotherapy in several types of human cancers [38].

Several studies have demonstrated that curcumin can effectively block the stimulation of NF-κβ by blocking the phosphorylation of IkBα through IKK. This hindrance of NF-κβ results in a reduction in the expression of several pro-inflammatory cytokines, nitric oxide synthase, MMP-1, MMP-3, MMP-9, COX-2, and cyclin D1. As a consequence, curcumin has the potential to decrease cell proliferation, growth, and tumour angiogenesis [39]. Furthermore, curcumin can directly inhibit COX-2 and 5-lipoxygenase, indicating its direct anti-inflammatory activity, which plays an active role in reducing inflammation in the tumour microenvironment [40].

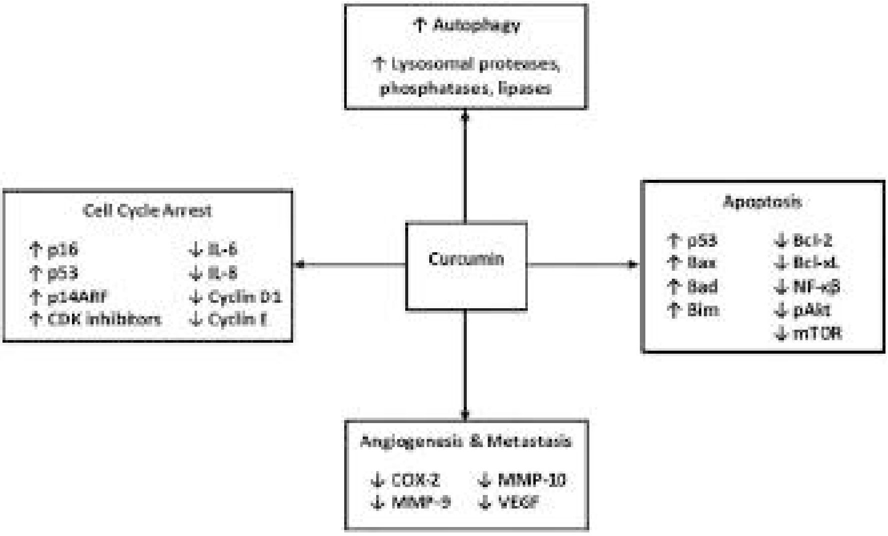

Fig. 6 Overview of the anticancer effects of curcumin. (Wilken et al. [38])

2.3 *Curcuma xanthorrhiza*

2.3.1 Taxonomy

Curcuma xanthorrhiza Roxb., also known as Java turmeric, is a plant in the Zingiberaceae family and is commonly grown in the Southeast Asian region [41]. Although it originates from Indonesia, it is also grown both in the wild and in cultivation in countries such as the Philippines, Thailand, Malaysia, and Sri Lanka [42]. The tuber of the plant has a circular shape and a yellowish skin on the outside as depicted in Fig. 7. The rhizomes have a fragrant aroma and a bitter taste. Historically, the rhizomes of *Curcuma* species have been used as a source of yellow dye, along with a spice and food preservative, flavouring agent, and remedy for treating various diseases, owing to their chemical compounds.

2.3.2 Phytochemistry

C. xanthorrhiza contains several major components as well as starch (48–59%), volatile oils (12%), including phellandrene, camphor, tumoural, cineol, borneol, and xanthorrhizol, sesquiterpenes (ar-curcumene, β-curcumene, bisabolane, germacone, lactone), flavonoids (apigenin, catechin, epicatechin, quercetin, kaempferol, luteolin, myricetin, naringenin), and curcuminoids [43].

The majority of these chemicals are curcuminoids and terpenoids, which possess essential biological properties [44]. Additionally, xanthorrhizol is the predominant secondary metabolite gained from the essential oil of its rhizome based on various studies [45]. However, other parts of the plant, such as the flower bract, are likely to contain various essential secondary metabolites. For instance, the flower bract

Fig. 7 The rhizome powder of *Curcuma xanthorrhiza* Roxb

consists of xanthorrhizol, α-curcumene, β-elements, *trans*-caryophyllene, β-farnesene, camphor, and isoborneol [46].

2.3.3 Usage as Chemoprevention

C. xanthorrhiza possesses multiple pharmacological activities, including anti-inflammatory, antioxidant, and anticancer effects by inhibition of glutathione transferase [47–49, 51].

Devaraj et al. [50] reported that the antioxidant properties of *C. xanthorrhiza* were evaluated in vivo on male Sprague–Dawley rats weighing between 150 and 200 g that were remedied with carbon tetrachloride (CCl_4) as a hepatotoxin. The hexane fraction of *C. xanthorrhiza* demonstrated its ability to act as a hepato-protector through its antioxidant properties [52]. In a separate study by Widyastuti et al. [53], the antioxidant characteristics of *C. xanthorrhiza* were investigated across diverse places. The antioxidant activity of *C. xanthorrhiza*'s methanol extract obtained from different locations was evaluated, as well as its overall phenolic and total flavonoid content.

Itokawa et al. [54] reported during the initial antitumour evaluation multiple compounds (ar-turmerone, β-atlantone, α-curcumene, and xanthorrhizol) that were extracted from *C. xanthorrhiza*'s rhizome and tested on rats with sarcoma 180 ascites. Notably, xanthorrhizol was found to significantly suppress the formation of tumour spots in lung tissue and the growth of tumour masses in the abdomen. Molecular analysis further demonstrated that xanthorrhizol exhibited inhibition of COX-2 expression, phosphorylated extracellular signal-regulated kinase (ERK), and matrix metalloproteinase-9 (MMP-9) in metastatic mice, providing additional support for its antitumour activity.

XTL is a highly active and abundant component found in the essential oil of the *Curcuma xanthorrhiza*'s rhizomes [55]. In addition to its nephroprotective and hepatoprotective effects demonstrated in male ICR mice remedied with cisplatin, XTL has also shown potential as a suppressor of carcinogenesis. The cytotoxic impact of XTL might be due to the presence of its phenol group, which is known to possess cytotoxic activity. XTL's anticancer mechanisms are varied, affecting various aspects of cellular growth and apoptosis. The morphology associated with apoptosis is typically described by chromatin condensation, DNA fragmentation, cell shrinkage, and elongated lamellipodia. The mechanisms underlying XTL's anticancer properties are strongly linked to its ability to function as anti-inflammatory agent and an antioxidant, induce apoptosis, and arrest the cell cycle [43].

Lee et al. [56] reported that XTL, the marker compound found in *C. xanthorrhiza*, contributes to its anti-inflammatory ability. Research has shown that XTL exhibits in vitro anti-inflammatory activity, as demonstrated by its ability to inhibit the production of nitric oxide (NO) and prostaglandin E2 (PGE2) in lipopolysaccharide-induced mice leukemic monocyte-macrophage cell RAW 264.7. This inhibition leads to a reduction in the expression of cyclooxygenase-2 (COX-2) and inducible nitric oxide synthase (iNOS). Also, XTL can inhibit the expression of COX-2, iNOS, TNF-α, and IL-6 in induced microglial cells. Moreover, the effects of XTL in vivo using mice with severe inflammation induced by 12-O-tetradecanoylphorbol-13-acetate (TPA) are known and found that XTL could inhibit the expression of ODC, COX-2, and iNOS in the mice dermis. These results suggest that XTL may play a role in reducing the levels of IL-6 and TNF-α, and inhibiting the activation of COX-2 and iNOS via the NF-kB pathway, leading to decreased production of PGE2 and NO. Additionally, preliminary findings suggest that the hydroxyl group of XTL is crucial for its pharmacological effectiveness as acetylation of this group leads to a loss of activity [57].

Furthermore, earlier studies have also demonstrated that xanthorrhizol can promote apoptosis by inducing the mitochondrial pathway (dependent on p53) in liver cancer cells (HepG2) and cervical cancer cells (HeLa) [58].

2.4 *Curcuma zedoaria*

2.4.1 Taxonomy

Curcuma zedoaria Rosc. is a plant species native to India that has also been widely cultivated throughout Southeast Asia, as well as Indonesia. The appearance of *Curcuma zedoaria* is similar to ginger on the outside and turmeric on the inside. This perennial plant can grow up to 1 m in height, and its main rhizome is ovoid in shape. The leaf blade of *Curcuma zedoaria* typically measures 80 cm in length and often features purple on both surfaces, blotches running along the midrib. This plant is illustrated in Fig. 8 [59–61].

C. zedoaria is a rhizomatous perennial plant with herbaceous, erect stems that develop into pseudo-stems, bulbs, and branches. It also has subterranean cylindrical rhizomes and succulent roots, with some roots producing terminal storage structures that can take the form of round or elongated tuber-like roots known as t-roots [62].

Fig. 8 The rhizome of *Curcuma zedoaria* (Christm.) Roscoe

2.4.2 Phytochemistry

Plants produce secondary metabolites that vary in type and concentration across different species. These metabolites serve as a defence mechanism against threats and are also used in plant identification. *Curcuma zedoaria* primarily contains terpenoids, predominantly sesquiterpenoids, phenolics, tannins, alkaloids, terpenoids, saponins, and steroids [59]. The rhizome oil of *Curcuma zedoaria* consists primarily of monoterpenoids (15–20%) and sesquiterpenoids (80–85%). The primary compounds of the essential oil of *C. zedoaria*'s rhizome are curzerene, epicurzerene, curzerenone, curdione, debromofiliforminol, β-sesquiphellandrene, 1,8-cineole, curcumenene, p-cymene, and α-phellandrene. On the other hand, the primary compounds of the leaf oil are dehydrocurdione, isoborneol, α-Terpinyl acetate, and selina-4, 7(11)-dien-8-one [63].

The content of secondary metabolites of essential oil from *Curcuma zedoaria* rhizome is influenced by various factors, including the environment in which the plant grows. A study of Indonesian *Curcuma zedoaria* oil found it to be comprised of 21 constituents, with 13 sesquiterpenoids (55.6%) and 7 monoterpenoids (40.1%) [64]. The main compounds of *Curcuma zedoaria* rhizome oil vary across different phytogeographical locations in Asia. *Curcuma zedoaria* from India is known to contain curzerenone, epi-curzerenone, or 1,8-cineole as major components, whereas epi-curzerenone or furanogermenone are the chemical markers of the original species for *Curcuma zedoaria* from China. On the other hand, the typical components of *Curcuma zedoaria* originating from Taiwan and Japan are curcumenol and dehydrocurdion [65].

Curcuma zedoaria rhizome extract using hexane and dichloromethane contains several compounds, including 16 dial dehydrocurcumin, curcumol, procurcumin, curcumone, labda-8,12diena-15, komoson II, zerumbone epoxide, zederon, 9- isopropylidene-2,6-dimethyl-11octylo[6. 2.1.01, 5]undec-6-en-8-ol, curcumanolide A, curcuzedoalide, germacrone, and gweicurculactone, furanodiene, germacrone-4,5-epoxide, calcaratarin A, isoprocurcuminol, germacrone-1,10-epoxide, and zerumin A [66]. In addition, 27 compounds were successfully isolated from *Curcuma zedoaria,* including curcumin, curcuminoids, curcumenone, dihydrocurdione, zedoaronediol, curcumanolide, furanodiene, furanodienone, zedorone, curzeone, curzerenone, germacrone, germacrone, 13-hydroxygermacroneethylpara methoxycinnamate, β-eudesmol, 18 β-turmerone, epicurzerenone, curzerene, 1,8-cineole, dihydrocurcumin, zingiberene, neocurdione, curdione, and α-phellandrene [67].

2.4.3 Usage as Chemoprevention

Curcuma zedoaria has been used as both a food and drug additive for a long time. In traditional cuisine, *C. zedoaria* possesses several activities, including anti-tumour/cancer, anti-inflammatory, pain relief, cholesterol-lowering, and antimicrobial effects [68]. Zedoary rhizome extracts exhibit anticancer, analgesic, antiallergic, anti-inflammatory, antibacterial, antifungal activities, and antiparasitic against *Entamoeba histolytica* [63]. Components obtained from *Curcuma zedoaria* extract such as curcumin, curzerenone, and zedoarone are effective as antifungals [69]. Zedoaria oil absorbed by sand granules in larvicidal tests against *Aedes aegypti* compared to abate has a potential effect with a lethal dose of 50% and 99% [70].

As analgesic, steroid and curcuminol components obtained through hydroalcoholic extract of the rhizome of this plant have stronger analgesic activity than the control drug because their mode of action does not involve the opioid system [71]. Methanol extract of *C. zedoaria* also has anti-inflammatory effects because it inhibits the activity of the COX-2 pathway and prostaglandin biosynthesis [72]. *Curcuma zedoaria* has a natural antioxidant content, namely diferuloylmethane, which comes from the essential oil of its rhizome. This oil can be used in preventing and slowing down the ageing process associated with degenerative diseases at a dose of 20 mg/ml [73].

Curdione has been presented to hinder the growth of breast cancer cell in vivo and in vitro. The mechanism behind this effect is believed to involve curdione-induced apoptosis, which is characterized by enhancing the expression of caspase-3, caspase-9, and cleaved Bax. Furthermore, it inhibits the proliferation of both MCF-7 cells and MDA MB-231 [74, 75]. Both curcuminoid and curcuminone compounds derived from *Curcuma zedoaria* demonstrated potent cytotoxic activity resistant to WEHI-3, HL60 leukaemia, and HUVEC cells, with IC_{50} values of 25.6, 106.8 μM, and 69.6 μM, respectively [76].

Malaysian and Indonesian *Curcuma zedoaria* essential oils, rich in camphor, zerumbone, and curzerenone, were found to exhibit strong cytotoxic activity resistant to lung, breast, and cervical cancer cells, with IC_{50} values ranging from 6.4 to 22 μg/mL in cell viability tests [64]. *Curcuma zedoaria* rhizome extract 0.1–0.2% given orally to experimental mice induced by murine B16F10 melanoma cells for 30–45 days increased the number of lymphocytes and NO production by macrophages, thereby inhibiting cytotoxic mediators of B16F10 melanoma cells and has an antimigratory effects on cancer cells that can inhibit metastasis [77].

The content of the polysaccharide fraction in the daily dose of *Curcuma zedoaria* should be 6.25 mg/kg in mice induced by S-180 sarcoma cells that can inhibit the growth of solid tumours by 50%, thereby reducing tumour size and preventing chromosomal mutations [78]. In addition, the content of ethyl p-methoxycinnamate, curcuminoids, bisdemothxycurcumin, isocurcumenol, and demothxycurcumin in *Curcuma zedoaria* can inhibit OVCAR-3 cells proliferation (human ovarian cancer), leukaemia (HL-60), NIH 3 T3 fibroblast cell metaplasia, HCT-15 and HT-2930 colon cancer cells, kidney embryonal cell malignancy (HEK293)14, and beta tumerone content in *Curcuma zedoaria* ethanol extract show an effect in inhibiting Hep-2 cells and hepatocellular carcinoma cells [79].

2.5 *Phyllanthus urinaria*

2.5.1 Taxonomy

Phyllanthus urinaria is classified as a competitive weed due to its substantial amount of seeds, tolerates shade well, and has a far-reaching system of root. Along the underside of its stems can be found numerous small green-red fruits as depicted in Fig. 9 [80]. The Euphorbiaceae family includes *Phyllanthus urinaria* L., a plant species that has been known for its medicinal properties. This species can be discovered in tropical areas across the globe, such as in India, Malaysia, Indonesia, Japan, and the United States [81].

2.5.2 Phytochemistry

Several functional compounds have been successfully isolated from *Phyllanthus urinaria* such as coumarins, carboxylic acids, flavonoids, tannins, and lignans as shown in Table 2. Polyphenols are the major bioactive components in *Phyllanthus urinaria,* including 9 flavonoids and 17 tannins. In addition, phenylpropanoids, including coumarins, lignans, and phenols, have been identified in *Phyllanthus urinaria*. Terpenoid class compounds such as 2 triterpenoids (oleanolic acid and glochidiol), 2 diterpenoids (spruceanol and cleistanthol), 1 sesquiterpene (cloven-2β, 9α-diol), and 1 monoterpene [(6*R*)-menthiafolic acid] were also successfully isolated from all *P. urinaria* plant extracts. Several other components have been isolated, consisting of glycosides, volatile oils, and steroids [81].

Fig. 9 *Phyllanthus urinaria* L.

Table 2 Chemical constituent of *Phyllanthus urinaria*

Category	Type	Compounds
Polyphenols	Tannins	Excoecarianin
		Trimethyl-3,4-dehydrochebulate
		Phyllanthusiin C
		Epigallocatechin, epicatechin-3-gallate, epicatechin, epigallocatechin-3-gallate
		Gallocatechin-3-gallate
		Repandinin B, furosin, repandusinic acid A, mallotinin, geraniin, acetonylgeraniin D, corilagin
		Phyllanthusin F, phyllanthusin G
	Flavonoids	Rhamnocitrin
		Rutin, quercetin
		Naringin
		Quercetin 3-O-α-L-(2,4-di-O-acetyl) rhamnopyranoside-7-O-α-L-rhamnopyranoside, quercetin 3-O-α-Lrhamnopyranoside
		Quercetin 3-O-b-D-glucoside, kaempferol 7-methyl ether
		Kampferol
Terpenoid	Sesquiterpene	Cloven-2β, 9 α-diol
	Monoterpene	(6R)-menthiafolic acid
	Diterpenoids	Cleistanthol, spruceanol
	Triterpenoids	28-norlup-20(29)-ene-3, 17β-diol, betulin, β-betulinic acid, 3-oxo-friedelan-28-oic acid, oleanolic acid, 3R-E-coumaroyltaraxerol, 3R-Z- coumaroyltaraxerol, glochidiol, oleanolic acid
Phenylpropanoid	Coumarins	Ellagic acid, brevifolincarboxylic acid
		Methyl brevifolincarboxylate
		Ethyl brevifolincarboxylate
	Lignans	Phyllanthin, hypophyllanthin, nirtetralin, niranthin, phyltetralin, (+)-dihydrocubebin, (+)-lyoniresiol, (7R,7’R,8S,8’S)-icariol A2, evofolin B, 4-oxopinoresinol, ()-syringaresinol,(−)-episyringaresinol
		Virgatusin, lintetralin, 5-demethoxyniranthin, urinatetralin
	Phenols	Ferulic acid, p-hydroxybenzaldehyde, 3,5-dihydroxy-4-methoxybenzoic acid, dehydrochebulic acid trimethyl ester
		Gallic acid, methyl gallate
Glycosides	Glycosides	β-Sitosterol-3-O-β-d-glucopyranoside
		Gentisic acid 4-O-b-d-glucopyranoside, syringin
Volatile oils	Jasmonate derivatives	(+)-Cucurbic acid, (+)-methyl cucurbate, methyl [lR,2R,2’Z]-2-(5′-hydroxy-pent-2′ -enyl)-3-oxocyclopentaneacetate
	Aldehyde derivatives	5-Hydroxymethyl-2-furaldehyde
Steroids	Steroids	β-Sitosterol, [3β,22E]-stigmasta-5,22-diene-3,25-diol
		Daucosterol

Du et al. [81]

2.5.3 Usage as Chemoprevention

Both extracts of aqueous and methanol of *Phyllanthus urinaria* have been shown to hinder the metastasis of A549 cells by suppressing their migration and invasion through the hypoxia and ERK1/2 signalling pathways, while the Fas receptor expression pathway is involved in the induction of apoptosis in human osteosarcoma 143B cells by a hot water extract [82, 83].

Phyllanthus urinaria is known to induce apoptosis along with antimetastatic action by targeting ERK and hypoxia pathways [84]. Corilagin is a polyphenolic tannic acid gained from *Phyllanthus urinaria* that is commonly known to selectively induce autophagy and apoptosis in cancer cells but not in healthy cells [85].

Several studies have scientifically proven the apoptosis-inducing activity of *P. urinaria* in tumour inhibition. Being a bioactive compound of *Phyllanthus urinaria,* corilagin induces apoptosis and has a mechanism through intrinsic and extrinsic pathways by downregulating procaspase-3, procaspase-8, PARP, procaspase-9, Bcl-2, and upregulating caspase-8, cleaved PARP, caspase-9, and Bax mediated by the production of ROS in the repression of breast cancer cells [85, 87]. The anticancer potential of *P. urinaria* may be attributed to several mechanisms shown in Table 3 [86].

Table 3 Apoptotic effects of extracts of *Phyllanthus urinaria* in cancer

Extract/ constituent	Cancer type	Study type	Chemopreventive mechanism
Corilagin	Breast carcinoma cells (MCF-7), MDA-MB-231 and xenograft	In vitro and in vivo	Downregulation of procaspase-8, procaspase-3, PARP, Bcl-2, and procaspase-9 and upregulation of caspase-8, cleaved PARP, caspase-9, and Bax
Aqueous	Human cancer cells	In vitro	DNA fragmentation, membrane blebbing, and formation of apoptotic bodies
Aqueous	Lewis lung carcinoma cell line	In vitro	Induce apoptosis via downregulation of Bcl-2 and upregulation of caspase-3
Aqueous	Human nasopharyngeal carcinoma cell line	In vitro	DNA fragmentation upregulated caspase-3 and decreased Bcl-2
Aqueous	Human osteosarcoma 143B cell	In vitro	Activation of Fas receptor/ligand expression, upregulated of bid, tBid, and Bax, and decreased Bcl-2
Corilagin	Ovarian cancer cell SKOV3	In vitro	Upregulated caspase-3 activity and loss of mitochondrial membrane potential
Alcohol	Stomach cancer cell line	In vitro	Apoptosis of MKN28 cell
Ethylene glycol, ethyl acetate, methanol, and water	Hep-2 (alveolar epithelial carcinoma cell line), MCF-7, HeLa (cervical cancer line)	In vitro	Activate caspase-3, caspase-8, and suppress Bcl-2

Saahene et al. [86]

Table 4 Antiangiogenic effects of extracts of *Phyllanthus urinaria*

Extract/ constituent	Cancer type	Study type	Chemopreventive mechanism
Aqueous	Mice bearing Lewis lung carcinoma cells, HUVECs	In vitro and in vivo	Suppressed neovascularization in mice
Aqueous and methanolic	MeWo and PC-3HUVECs	In vitro	Suppressed migration, invasion, and microcapillary like-tube structure formation in HUVECs
Aqueous	Human osteosarcoma xenograft mice	In vivo	Inhibition of cluster of differentiation 31
Ellagic acid	Chorioallantoic membrane in chicken embryo	In vivo	Inhibition of MMP-2
Methanolic	Male Sprague–Dawley rats, HUVECs	In vitro and in vivo	Suppression of vascular growth and tube formation
Aqueous	Hepatocellular carcinoma	In vitro and in vivo	Inhibition of migration

Saahene et al. [86]

The bioactive component of *Phyllanthus urinaria*, ellagic acid, can be in anti-angiogenic in vivo studies by hindering MMP-2 [88]. Methanol extract of *Phyllanthus urinaria* at a concentration of 100 μg/mL can inhibit blood vessel growth by 56.7% and tube formation by 35.6% [89]. Thus, angiogenesis regulation has been shown to suppress tumour progression. *Phyllanthus urinaria* can inhibit angiogenesis to suppress some cancers as shown in Table 4 [86].

In an in vivo study using mice bearing Lewis lung carcinoma, the development of *Phyllanthus urinaria* angiogenic inhibitors resulted in a significant reduction in tumour progression and size, as well as inhibition of tumour neovascularization and induction of apoptosis. Notably, these effects were achieved with limited cytotoxicity from the extract [90]. *Phyllanthus urinaria* possesses the strongest dose-dependent antimetastatic and antiangiogenic activity via reduction of matrix metalloproteinase-2 [91]. The mechanism underlying the suppression of human osteosarcoma xenograft growth by *Phyllanthus urinaria* is the induction of apoptosis characterized by increased Bax/Bcl-2 ratio and inhibition of differentiation cluster 31 through regulation of mitochondrial function and fusion proteins [92].

2.6 *Gynura procumbens*

2.6.1 Taxonomy

Gynura procumbens is a plant species native to Southeast Asia, commonly found in Indonesia, Malaysia, the Philippines, and Thailand. It is an annual evergreen shrub that typically grows to a height of 1–3 m and has distinctive purple and fleshy stems.

Fig. 10 *Gynura procumbens*

The leaves are ovate or lanceolate, measuring between 3.5 and 8 cm in length and 0.8 and 3.5 cm in width. The plant produces panicle-shaped yellow flower heads, each measuring approximately 1–1.5 cm in length as shown in Fig. 10 [93, 94].

2.6.2 Phytochemistry

The leaves of *Gynura procumbens* are often consumed as food, with no toxic effects. *Gynura procumbens* is known to contain many active chemical constituents, including tannins, flavonoids, terpenoids, sterol glycosides, and saponins. Additionally, it is rich in some constituents, such as kaempferol-3-O-β, kaempferol, and 3,5-dicaffeoylquinic acid methyl ester, quercetin, terpenoids, alkaloids, saponins, tannins, and astragalin [94, 95]. Caffeoylquinic acid and its derivatives are the most important constituents isolated from the leaves or aerial parts of *Gynura procumbens* [96].

2.6.3 Usage as Chemoprevention

Gynura procumbens is a necessary tropical medicinal plant. The medicinal properties of this substance have been the subject of numerous studies, particularly in Southeast Asian countries. *Gynura procumbens* has been used as medicine for household remedies against various human diseases such as fever, rashes, kidney, migraine, constipation, hypertension, diabetes mellitus, and cancer. In addition, *Gynura procumbens* leaves or leaf extracts have activities as anti-herpes simplex virus, antihyperglycaemic, antihyperglycaemic and antihyperlipidemia, anti-inflammatory, reducing hypertension, antiproliferation in human mesangial cells, antioxidant, and anticarcinogenic. Moreover, the presence of defence proteins has been identified in *Gynura* leaves such as miraculin, peroxidase, and thaumatin-like protein. The potent protein fraction SN-F11/12 is known to hinder breast cancer proliferation in vitro [97, 98].

Meiyanto et al. [99] examined that for the DMBA-induced breast cancer development in rats, ethanolic extract of *G. procumbens* has potential chemopreventive-resistant properties. The investigation discovered that overseeing the concentrate at dosages of 250, 500, and 750 mg/kgBW decreased growth frequency by 60%, 30%, and 20% individually. The effective doses in suppressing tumour multiplicity are 500 and 750 mg/kgBW, while the dose of 250 was less effective in this case.

Hamid [100] investigated that inhibiting changes in the epithelial cells of the mammary gland, as demonstrated through histopathological changes, resulted in the potential of ethanolic extract of *Gynura procumbens* leaves in preventing breast cancer. Two distinct doses were administered to Sprague–Dawley rats for treatment. These were extracted (300 and 750 mg/kg bw) for 7 weeks. DMBA was used to induce breast cancer, and tumour progression was monitored until 12 weeks after the last DMBA initiation. Histopathological changes were quantified using the HE method. Results showed that both doses of the extract significantly inhibited mammary carcinogenesis.

Nurulita et al. [101] reported the cytotoxic properties of the ethyl acetate fraction of *Gynura procumbens* leaves (FEG) on colon and breast cancer cells, as well as its selectivity. Quercetin was identified in FEG using both HPTLC and HPLC, but it was not found to be the main active compound. FEG inhibited the growth of WiDr, MCF-7, and T47D cells and demonstrated lower effects on T47D cells than on WiDr and MCF-7 cells. The growth inhibitory effect of quercetin was higher on WiDr and MCF-7 cells compared to FEG. FEG was found to be less inhibitory towards NIH3T3 cells than all other cell lines, demonstrating a selective effect against cancer cells. The selectivity index of FEG on WiDr, MCF-7, and T47D cells was 4.97, 2.77, and 7.79, respectively.

Shwter et al. [102] reported that the administration of *Gynura procumbens* to the rats in this study resulted in a significant increase in colon GST activity. GST is an important enzyme in the detoxification of carcinogens and is involved in the conjugation of electrophilic compounds with glutathione, making them more water-soluble and easier to excrete [103]. The induction of GST activity by *Gynura procumbens* suggests that it may have chemopreventive potential by enhancing the detoxification of carcinogens [104, 105].

Furthermore, rats that were fed with *Gynura procumbens* had considerably lower numbers of aberrant crypt foci (ACF) compared to the carcinogen group ($P < 0.001$). It also appeared that the frequency of ACF in the distal colon was substantially greater than that in the proximal colon in all experimental groups ($P < 0.001$). Nonetheless, the quantity of ACF observed in both the distal and proximal colon was significantly decreased in 500 mg/kg *Gynura procumbens*, 250 mg/kg *Gynura procumbens*, and reference groups (21.40 ± 7.09; 23.20 ± 4.7, and 32.0 ± 2.2, respectively) in comparison to the carcinogen group (130.60 ± 21.93) ($P < 0.001$). The experimental groups that received 500 mg/kg and 250 mg/kg *Gynura procumbens* demonstrated a reduction of approximately 83.6% and 82.2%, respectively, in the total number of crypts compared to the carcinogen group [102]. Earlier research has validated the utility of ACF as a biomarker for colon cancer [106].

In addition, Shwter et al. [102] showed that the superoxide dismutase activity (U/mL) in rats fed with *Gynura procumbens* 250 mg/kg was found to be the highest at 11.55 ± 0.331, followed by rats fed with *Gynura procumbens* 500 mg/kg at 8.41 ± 0.941, while the carcinogen group rats fed with AOM showed the lowest activity at 5.87 ± 0.311. The results showed that treatment diets utilized in feeding the rats had significantly higher SOD activity compared to the carcinogen group. SOD is an enzyme that plays a crucial role in preventing the formation of ACF by converting superoxide anion radicals, which are potent carcinogens, into hydrogen peroxide and molecular oxygen. The H_2O_2 produced by SOD is additionally diminished to water by catalase. These findings are consistent with previous studies demonstrating lower SOD activity in various tumour cell lines [107, 108].

2.7 *Garcinia mangostana*

2.7.1 Taxonomy

Garcinia mangostana is a tropical plant that lives and is cultivated in Southeast Asia. This plant can grow up to 6–25 m in height and has a dark purple to reddish fruit colour [109]. The main feature of this fruit, which is known as 'mangosteen', is that at the end there is a simple inflorescence as depicted in Fig. 11 [110].

2.7.2 Phytochemistry

Polyphenolic compounds were identified through phytochemical screening of *Garcinia mangostana* as well as anthocyanins, flavonoids, xanthones, and benzophenones as illustrated in Fig. 12 [111]. But the main bioactive compounds in *Garcinia mangostana* are xanthone derivatives. Being members of the polyphenol group, xanthones are secondary metabolites that are recognized by their tricyclic aromatic ring structure [112]. This compound was obtained from the extraction results, especially in the pericarp of the mangosteen fruit.

Garcinia mangostana has yielded more than 50 isolated xanthones. Phytochemical studies conducted on the DCM fraction from *Garcinia mangostana* rind resulted in five xanthones known as 9-hydroxycalabaxanthone, 8-deoxygartanin, gartanin, γ-mangostin, and α-mangostin [113]. Meanwhile, the ethanol extract produced 14 isolates, including mangosteen, 8-deoxygartanin, garninon, gartanin, 1,5,8-

Fig. 11 The mangosteen fruit or *Garcinia mangostana*

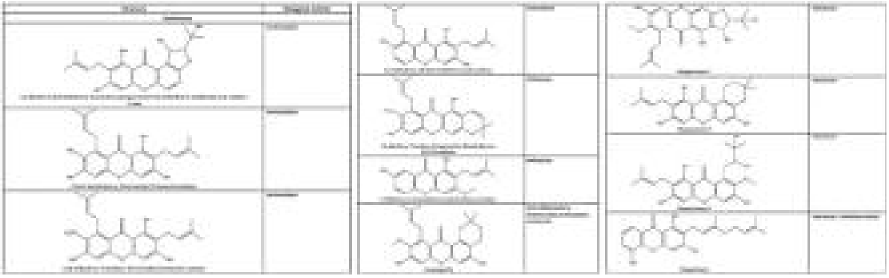

Fig. 12 Chemical compound and its biological activity. (Murthy et al. [111])

trihydroxy-3-methoxy-2[3-methyl- 2-butenyl] xanthone, trapezifolixanthone, padiaxanton, tovophyllin A, garnison B, 1,3,7-trihydroxy-2,8-di-(3-methylbut-2-enyl)xanthone, mangosteen D, 2-geranyl-1,3,5-trihydroxysanthone, 1,7-dihydroxy-2-(3-methylbut-2-enyl)- 3-methoxyxanthone, and 7-O-Demethyl mangostanine. The most abundant and frequently isolated xanthone for research is α-mangostin [114].

2.7.3 Usage as Chemoprevention

There are various biological activities shown by *Garcinia mangostana* such as antioxidant, anti-inflammatory, and anticancer effects. In vivo test results demonstrated which extracts and isolates from *Garcinia mangostana* can increase antioxidant enzymes, like SOD, CAT, GPx, and GSH, or by reducing markers of oxidative stress, such as MDA levels [115]. Compounds that contribute to the antioxidant activity of *Garcinia mangostana* include α-mangostin, γ-mangostin, gartanin, 8-deoxygartanin, and mangostanin [111].

In vivo tests have demonstrated that *Garcinia mangostana* can serve as an effective anti-inflammatory agent through several mechanisms, including repression of eosinophil recruitment via PI3K inhibition, as well as decreasing levels of OVA-induced IgE, cytokines TGF-β1 and (IL-4, IL-5, IL-13), and downregulating NFκB p65 levels in nuclear protein. These activities are contributed by α-mangostin and γ-mangostin [116]. Mangostin compounds also can inhibit bacterial growth [117].

The pericarp of *Garcinia mangostana* fruit contains xanthones, which have been found to exhibit antitumour effects. Many of the compounds in pericarp extract have been shown to be active in cancer models in various organs, including the colon, breast, lung, cervix, prostate, etc. The use of mangosteen extracts has been associated with several mechanisms, such as apoptosis induction, metastasis prevention, and angiogenesis prevention.

In an in vitro study, α-mangostin can induce apoptosis in oral cancer cells. The effects of xanthone derivatives include increased Bax expression and higher levels of caspase-3 and cleaved PARP, which leads to G1 phase cell cycle arrest. α-Mangostin also reduces CDK4, CDK2, cyclin D, and cyclin E levels, while increasing levels of p21 and p27 [118]. Other studies reported that α-mangostin induced apoptosis in animal models with oral cancer. The effect that can be observed is declined tumour volume and weight [119].

Carcinogenesis can be halted by inhibiting angiogenesis, which is a viable strategy due to the role of VEGF in stimulating endothelial cell proliferation, migration, and differentiation to form new blood vessels. VEGF receptor binding results in conformational changes and activation of the MAPK and PI3K/Akt signalling pathways [120]. In vitro studies have shown that α-mangostin can reduce VEGF expression in T47D breast cancer cells and inhibit its biological effects by interfering with its signalling pathway [121].

Moreover, α-mangostin has been found to restrain VEGF-induced hyper-permeability, increase migration, proliferation, and tube formation in retinal endothelial cells and limit vascular growth through the suppression of VEGF-induced VEGFR2 phosphorylation, as reported by Jittiporn et al. [122]. In addition, a distinct study exhibited the suppressive impact of α-mangostin on VEGF-triggered migration, proliferation, and formation of tubules from human umbilical vein endothelial cells [123].

2.8 *Morinda citrifolia*

2.8.1 Taxonomy

Morinda citrifolia is a small tree or an evergreen shrub that is native to Southeast Asia. It can grow up to 10 m in height and has a deep taproot and a far-reaching lateral root system that makes it hard to remove once established. The bark of the tree is grey or light brown, while the sapwood is soft and yellow-brown in colour. The leaves are opposite, glossy, membranous, and deeply veined as depicted in Fig. 13. The fruit changes from green to yellow to white as it ripens and has a potent smell that is sometimes described as unpleasant [124]. *Morinda citrifolia* has been consumed for more than 2000 years for various therapeutic purposes [125].

2.8.2 Phytochemistry

Morinda citrifolia has anthraquinone compound found in seeds, heartwood, root, and flowers. Ricinoleic acid was found in the seed. On the other hand, the root contains morenone 1, morenone 2, 7-hydroxy-8-methoxy-2-methylanthraquinone, and damnacanthal. From the heartwood, three anthraquinones were isolated: morindone, physcion, and anthraquinone glycoside. The flowers of *M. citrifolia* were identified as having one anthraquinone glycoside and two flavone glycosides. Besides, β-sitosterol and ursolic acid were found in the leaves. Numerous studies have found that *M. citrifolia* fruits contain a variety of chemical components, including nonvolatile compounds such as acetyl derivatives of asperuloside, caproic acid, glucose, and caprylic acid [126]. In addition, the juice extract of these fruits has been reported to contain over 50 volatile compounds, including terpenes, aldehydes, ketones, and sulphur compounds [127].

Fig. 13 The fruit of *Morinda citrifolia*

2.8.3 Usage as Chemoprevention

Morinda citrifolia has been traditionally used as a medicinal plant for several ailments, such as diabetes, antioxidant, and cancer. All parts of the plant have been utilized for their therapeutic properties. Numerous studies have highlighted the pharmacological activity of the fruit, which contains alkaloid compounds that have been found to inhibit α-glucosidase [128].

Batista et al. [129] reported that polysaccharide extracted from *Morinda citrifolia* significantly reduces oxidative damage by increasing GSH levels and reducing the content of MDA and NO_3/NO_2. In addition, polysaccharides can inhibit IL-1β, COX-2, and TNF-α expression. These results indicate that polysaccharide exhibits an anti-inflammatory effect on colitis by reducing inflammation response and oxidative stress in the inflamed colon. Hence, *Morinda citrifolia* extract has therapeutic potential against inflammation diseases, such as inflammatory bowel disease [130].

In a study conducted on rats, researchers investigated the potential neuroprotective effects of *M. citrifolia* juice against ischaemic stress-induced brain damage [131]. Specifically, they focused on the impact of fruit juice in preventing the growth of post-ischaemic glucose intolerance as this is thought to be a mechanism of brain protection. The results showed that *M. citrifolia* juice was effective in protecting the brain from damage and preventing the development of glucose intolerance. Besides, the neuroprotective effect of *M. citrifolia* juice was evaluated in scopolamine-induced rats [132]. The results demonstrated that the juice had a beneficial effect in preventing memory loss and protecting against oxidative damage caused by scopolamine. This was achieved by maintaining superoxide dismutase (SOD) activity. The findings suggest that *M. citrifolia* juice could potentially serve as an alternative therapy in the prevention of Alzheimer's disease.

Purwanto and Martono [133] reported that *M. citrifolia* fruit's ethanolic extract exhibited varying effects on class mu GST activity, with concentrations of 1% and 5% (w/v) inducing the activity while 10% (w/v) inhibiting it. In the case of DMBA treatment, all concentrations of the extract significantly suppressed class mu GST activity in rats' lungs. These findings show that it is potentially becoming a supportive agent for chemotherapy drugs. Numerous in vivo and in vitro experiments have investigated the potential anticancer effects of *Morinda citrifolia* extracts, as depicted in Table 5. These studies have highlighted the plant's ability to induce apoptosis, inhibit angiogenesis, prevent migration, and suppress tumour growth and proliferation, leading to the elimination of cancer cells shown in Table 6 [134].

Morinda citrifolia is capable of hindering the proliferation of cancer cells by suppressing the AKT/NF-κB signalling pathway, leading to apoptosis [135]. Additionally, *Morinda citrifolia* downregulates the expression of Ki67 cell proliferation and PCNA protein, inhibits the antiapoptotic protein Bcl-2, and upregulates apoptotic caspase-3 protein to increase the apoptotic pathway and eliminate tumour cells. Moreover, this plant has demonstrated the ability to interfere with cell migration, inhibiting metastasis and halting tumour cell development [136].

2.9 *Nigella sativa*

2.9.1 Taxonomy

Nigella sativa flower has 5–10 petals and is light blue and white in colour. *Nigella sativa* seeds, also known as 'Alhabba Al-sauda' in Arabic and 'Kalvanji' in Urdu and Hindi, are often used especially in the Middle Eastern countries as depicted in Fig. 14 [137, 138].

2.9.2 Phytochemistry

Nigella sativa has various active ingredients as well as thymoquinone and monoterpenes [139]. Thymoquinone isolate is composed of several compounds, including p-cymene nigeglanine, dithymoquinone, thymohydroquinone, thymol, nigellicine, nigellidine, nigellimine, t-anethol, and 4-terpineol as illustrated in Fig. 15 [140, 141]. *Nigella sativa* also can be a source of vegetable oil because it contains various fatty acids, including linoleic acid and oleic acid [142].

Nigella sativa seeds are usually used as a herbal medicine for various ailments. *Nigella sativa* or black cumin has a variety of nutrients. More than 20% of carbohydrates are contained in the seeds. In addition, black cumin seeds have a protein content of 3.7–4.7% and 3.4–4.7% fibres. Elements of vitamins and minerals also include various nutrients that plants have [141].

2.9.3 Usage as Chemoprevention

Nigella sativa has been found to exhibit significant antiproliferative effects resistant to several cancers, including liver, colon, breast, cervix, lung, pancreas, prostate, etc. Multiple in vitro and in vivo studies have reported that the plant's anticancer activity is treated by modulating various biological processes and pathways [142].

The subject that was used to study the antitumour effect of thymoquinone, an isolate from black cumin, was a mouse tumour xenograft model of breast cancer. Treatment by inducing p38 phosphorylation and ROS production in breast cancer cells results in significant pro-apoptotic and antiproliferative effects. Furthermore,

Table 5 Pre-clinical evidence obtained from plant extract

Cancer type	Cell model	Intervention description	Comparator/ combination	Mechanism of action
Breast	Human breast tumour explant	Noni juice	Not started	Inhibition of capillary growth and degenerate newly formed vessels
	CYP 2C19 enzymes isolated from human recombinant Sf9 insect cells	Fruit juice	Not started	Dose-dependently inhibited CYP 2C19 aromatase enzyme which decreases oestrogen production
	MDA-MB-231 human breast cancer carcinoma	Unclear (butanol extract)	LPS	Induced apoptosis through interaction with TLR4
	MCF-7 human breast cancer cell; MDA-MB-231 human breast cancer carcinoma	Fractionation of 90% ethanolic fruit extract	Paclitaxel (cytotoxicity assay)	Arrested cell proliferation and cell cycle; induced apoptosis; increased caspase activities; decreased ROS production and mitochondrial membrane potentials
	MCF-7 human breast cancer cell	95% ethanolic leaf extract	Not started	Inhibited cell migration; suppressed migration of cancer cells
Lung	A549 human lung adenocarcinoma cells; LL2 mouse Lewis lung carcinoma cells	50% ethanolic leaf extract	Erlotinib 50 mg/kg	Extract inhibited cell proliferation and induced apoptosis; induced cell cycle arrest and activated caspase apoptotic activity
	A549 human non-small cell lung cancer (NSCLC)	Fermented fruit juice	Not started	Induced apoptosis, inhibited proliferation, invasion, and migration of cells; downregulated phosphorylation of AKT, p50, and STAT3 protein
	A549 human lung carcinoma cells	Fruit juice	Not started	Inhibited the manganese-induced HIF-lα protein expression; interfered with manganese's signalling to activate PKB, ERK-1/2, JNK-1, and S6; repressed the induction of HIF-Iα protein by desferoxamine or IL-Iβ

(continued)

Table 5 (continued)

Cancer type	Cell model	Intervention description	Comparator/ combination	Mechanism of action
	A549 human lung cancer	Dried seeds	Not started	Induced intracellular nuclear damage; induced apoptosis and cell cycle arrest; accumulated ROS production and disruption of mitochondrial potential
Eye	Y79 retinoblastoma cell	Fruit extract	Not started	Apoptotic morphology observed; modulated caspase activation
Leukaemia	Jurkat cells (human T lymphocytes)	50% ethanol leaf extract	Not started	Induce apoptosis and cell cycle arrest; enhanced caspase activities

Chanthira Kumar et al. [134]

thymoquinone was found to inhibit the expression of antiapoptotic gene proteins, including survivin, Bcl-xL, XIAP, and Bcl-2 in breast cancer cells and breast tumour xenografts. Additionally, thymoquinone was observed to increase the levels of superoxide dismutase, catalase, and glutathione in rat liver tissue [138].

The proliferation of human LoVo colon cancer cells can be significantly reduced by administering 20 μmol/L thymoquinone. This treatment can also lower the levels of p-Akt, p-PI3K, β-catenin, and p-GSK3β, thereby inhibiting the downstream COX-2 expression. As a result, COX-2 expression is reduced, leading to lower PGE2 levels and suppressed EP2 and EP4 activation [143]. In another study, thymoquinone was found to increase the total cell death index and activate apoptosis at 2 μM, with the effect decreasing as the dose increased. Thymoquinone can also cause mitochondrial outer membrane permeability (MOMP) and activate autophagic cell death with the stimulation of p38 and JNK in CPT-11-R LoVo colon cancer cells [144].

Thymoquinone has been studied for its potential role in inhibiting the migration, proliferation, and invasion of lung cancer cells. In particular, administering thymoquinone at a dose of 10, 20, or 40 μmol/L has been found to suppress PCNA, MMP9, cyclin D1, and MMP2 mRNAs. It can also inhibit MMP2 gelatinase activity, reduce the expression of MMP9 and cell cycle inhibitor P16, and inhibit the migration, invasion, and proliferation of A549 cells by reducing the ERK1/2 pathway [145, 148]. In other studies, thymoquinone has shown effectiveness against lung cancer cell proliferation by increasing Bax expression, downregulating Bcl2 protein, increasing the Bax/Bcl2 ratio, increasing p21 expression, decreasing cyclin D expression, downregulating IKK1 and NF-kappa B levels, and increasing TRAIL 1 and 2 receptor expression [146, 147].

Table 6 Pre-clinical evidence from *M. citrifolia*'s phytochemistry

Cancer type	Cell model	Phytochemical	Comparator/ combination	Mechanism of action
Breast	4TI mouse breast cancer cell; MCF-7 human breast cancer cell; MDA- MB-231 human breast cancer carcinoma	Nordamnacanthal	Not started	Increased population of early apoptotic and late apoptotic cells; induced cell cycle arrest
	MCF-7 human breast cancer cell	Damnacanthal	Not started	Induced apoptosis and stimulate cell cycle arrest; activation of caspase activity; enhanced expression of pro-apoptotic genes and proteins
	MCF-7 human breast cancer cell	Damnacanthal	Doxorubicin (0.2–0.55 μg/ mL)	Induced cell cycle arrest and apoptosis in combination treatment; upregulation of pro-apoptotic proteins and downregulation of antiapoptotic proteins in combination treatment
	MCF-7 human breast cancer cell	Polysaccharides	Not started	Induced DNA damage by apoptosis through activation of p53 and caspase-3 proteins
Liver	Hep G2 human hepatocellular carcinoma	Damnacanthal	Not started	Affected cell survival; inhibited growth and clonogenic potential; induced apoptosis; inhibited cell migration
Skin	MUM-28 human melanoma cell	Damnacanthal	Not started	Inhibited proliferation and increased apoptotic; increased caspase activities; upregulated pro-apoptotic protein
Colon, prostate, and	HCT-116 human colon cancer cell; HT-29 human	Damnacanthal	Not started	Suppression of cell growth; affected cell cycle regulation

Fig. 14 The seeds and the flowers of *Nigella sativa* Linn

2.10 *Moringa oleifera*

2.10.1 Taxonomy

Moringa oleifera is a member of the Moringaceae family and the most widely grown species [149]. *Moringa oleifera*, which is referred to as the drumstick tree and a versatile plant that is considered a miracle tree, is depicted in Fig. 16. Every part of the plant is utilized for various purposes and is deemed to have medicinal significance. Moreover, the plant is an exceptional source of both essential nutrients and bioactive compounds. It is a very nutrient-dense vegetable tree with a wide range of applications. The tree itself is relatively slender, with drooping branches. Nevertheless, it is typically cut back annually to a height of 1 m or less and then left to regrow to maintain pods and leaves within reach [150].

2.10.2 Phytochemistry

A wealth of bioactive substances, including phenols, glucosinolates, tocopherols, carotenoids, and ascorbic acid, have also been found in *Moringa oleifera* plants [149]. Vitamin A is abundant in fresh leaves from *M. oleifera*. Carotenoids with pro-vitamin A potential are abundant in *M. oleifera* leaves. In addition, *M. oleifera* leaves have a higher content of vitamin C than oranges, at 200 mg/100 g. *M. oleifera*

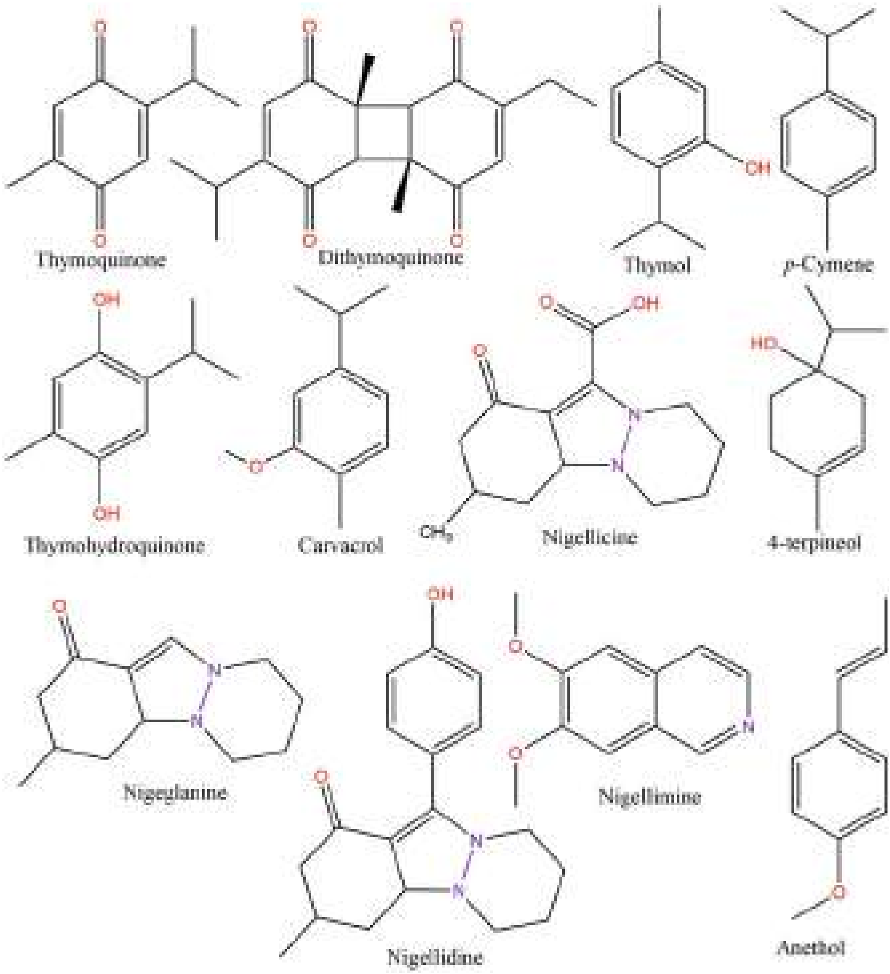

Fig. 15 Some compounds have been isolated from *Nigella sativa.* (Ansary et al. [141])

fresh leaves provide high levels of vitamin E that are comparable to those in nuts [151]. This is significant because vitamin E has been found to suppress cell proliferation in addition to acting as an antioxidant [152, 153].

Moringa oleifera has several phytochemicals that are found in the plant's leaf, branch, seed, pod, and root. According to Flora and Pachauri [154], the main phytochemicals of *M. oleifera* include glucosinolates, phenolics, flavonoids, crude fats, fatty acids, key nutrients, minerals, and total protein. In addition, glucosinolates are secondary metabolites that identify Brassicales plants, including *M. oleifera,* and are only found in the Brassicales order except for the root; most of the *M. oleifera* plant is covered in glucosinolates. *M. oleifera* has a high concentration of aromatic glucosinolates, including benzyl glucosinolates (glucotropaeolin), 2-phenylethyl

Fig. 16 Images of *M. oleifera* leaves and seeds

glucosinolates (gluconasturtiin), and p-hydroxybenzyl glucosinolates (sinalbin). Furthermore, the predominant substance found in *M. oleifera*'s leaves is benzyl glucosinolates [155].

Many compounds of eight *M. oleifera* cultivars from India were found when the carotenoid examined yielded luteoxanthin, lutein, zeaxanthin, and β-carotene. Lutein was found to be the main component of the leaves and fruits, making about 53.6 and 52.0%, respectively, of the total carotenoids. In addition, 90 mg/g, 8 g/mL, and 27 g/mL of total phenolic, flavonoid, and β-sitosterol components were found in the leaves of *M. oleifera* [156, 157]. Also, an abundance of different bioactive substances like glycerol-1-9-octadecanoate, glucosinolates, isothiocyanates, and glycoside compounds are additional anticancerous elements [158].

2.10.3 Usage as Chemoprevention

In Indonesia, *Moringa* is a plant that grows as shrubs or trees and is extensively distributed. The locals utilize this herb to treat a variety of sickness concerns. The indigenous people of Timor Island use the *Moringa* plant to cure anaemia, hypertension, respiratory issues, ear and mouth infections, and skin and respiratory illnesses [157]. There have been various biological activities in *M. oleifera*'s plant, including protection against gastric ulcers, antidiabetic, anti-inflammatory, and anticancer [159].

M. oleifera recently showed the promising cytotoxic and antitumour properties. The anticancer activity of *M. oleifera* is not limited to its pure compounds. In a study conducted by a research team, they examined that the effects of an aqueous extract of *M. oleifera* pods on colon cancer showed a huge decrease in the nuclear antigen indices of growing cells ($P < 0.05$) and suppressed the expression of inducible iNOS and COX-2, which are associated with cancer development [160]. This suggests that the extract has potential as a natural anticancer agent. The inhibition of leaves extract (200 μg/ml) rate reached 80%. HepG2 liver cancer cell survival may be decreased by an alcoholic extract of *M. oleifera*'s fruit [161]. The antitumour efficacy against colon cancer cells was proven in 2015. According to an in vitro study, colon and breast cancer cells were cytotoxic to *M. oleifera*'s alcoholic leaf and bark extracts (above 500 g/ml). It decreased the proliferation of HCT-8 and MDA-MB-231 cells and blocked in G2/M phase [162].

Several studies suggest that *M. oleifera* is safe and effective in treating various conditions. For instance, a study reported *Moringa* leaf's extract improved the efficacy of chemotherapy in reducing human pancreatic cancer cells growth, such as p34, Colo 357, and Panc-1, by hindering the NF-kB signalling pathway [163]. Similarly, the use of *Moringa* leaf extract reduced the growth of B16F10 melanoma cells and induced the death of 22% of cancer cells [164].

M. oleifera has been found to obstruct several signalling pathways, including the nuclear factor-kappa B (NF-κB) and STAT5 signalling pathways, as well as to a lesser extent the STAT1/STAT2 signalling pathways. GMG-ITC (4-(α-l-rhamnopyranosyloxy)-benzyl ITC) is an active inhibitor of these pathways, which are all involved in cancer [165]. *Moringa* has also been shown to produce reactive oxygen species (ROS) in cells, which can lead to apoptosis by upregulating caspase 3 and caspase 9, both of which are part of the apoptotic pathway. This ROS production is thought to be a potential anticancer agent produced by *Moringa*. Furthermore, research has found that concentrates from *Moringa* can increase glutathione-S-transferase expression, which helps defend cells against oxidative damage [166]. The table of anticancer efficacy of *M. oleifera* is shown in Table 7 [167].

Bhadresha et al. [168] reported evaluating the in vitro anticancer effects of *M. oleifera* leaf extracts. The human cancer cell line A549 experienced a dose-dependent, substantial reduction in cell growth when treated with *M. oleifera* leaf extracts. *M. oleifera* leaves aqueous extracts were examined for cytotoxicity against lung cancer A549 cell lines at a range of various concentrations of 100–500 g/ml by using MTT assay. The percentage of A549 cells is still viable after 24 h of incubation with treatments compared to controls. The results showed that sensitive A549 cells lost viability at doses of 400 and 500 g/ml, causing 30% and 15% more cell death than the control, respectively ($P < 0.05$).

2.11 *Zingiber officinale*

2.11.1 Taxonomy

Zingiber officinale, or ginger, is used as a spice, flavouring agent, food, and herbal medicine because of its pungent taste. Aromatic rhizomes (underground stem) are depicted in Fig. 17. Zingiberaceae is the family of flowering plants, and *Zingiber* is the genus. *Zingiber officinale* (ginger) is a species of perennial plant with yellow flowers. The rhizomes, or tuberous roots, of the ginger plant offer a flavourful and aromatic scent [169, 170].

Furthermore, the ginger order of flowering plants are Zingiberales, which have about 53 genera, 8 families, and more than 1300 species. The tropics are habitats to many Zingiberales species, many of which are used as shade plants. Both species with bilateral flowers and those with radially symmetrical flowers can be found in the monocot order Zingiberales [171].

Table 7 Mechanism of action from *M. oleifera* in cancer

Type of effect	Plant of *M. oleifera*	Type of extract	Treatment doses/ extract	Animal model/cell lines	Outcome
Anticancer	Leaves	Extract	3125%	Wistar rat oral cancer cells	Reduced VEGF expression in oral cancer cells in Wistar rats
	Leaves	Ethanolic extract	3125%	Male Wistar rats	Decreased the expression of HSF1 in oral cancer induced by benzo[a] pyrene
	Leaves	Aqueous extract	1 gr/10 mL boiling water	Human pancreatic epithelioid carcinoma cell line PANC-1	Pancreatic cancer cell survival and metastatic activity were significantly decreased It further inhibited tumour growth
	Leaves	Active MO-derived fractions	3-Hydroxy-β-ionone	SCC15 cell line	MO extracts and its 3-hydroxy-β-ionone fraction provided the anticancer activity by inhibiting development and inducing apoptosis of SCC15 cell lines
	Seeds	Water, 80% ethanol extract and ethanolic extracted powder further fractionated in other solvents	0, 50, 100, 200, 300, and 500 μg/mL	MCF7 breast cancer cell	Crude water extract, hexane, and dichloromethane fractions of crude ethanolic extract of seeds inhibited the proliferation of MCF7 with IC50 values 280, 130, and 26 μg/mL, respectively

Arora and Arora [167]

Fig. 17 The fresh rhizome of *Zingiber officinale* plant

2.11.2 Phytochemistry

Zingiber officinale has been chemically analysed and found to have more than 400 constituents. *Zingiber officinale* contains 3–8% lipids, 38–70% carbohydrates, phenolic chemicals, and terpenes as the main components of ginger. The bioactive components of ginger, notably phenolic chemicals and terpenes, are responsible for its nutritional benefits. Some of these substances, including those from the groups of shogaols, gingerols, paradols, zingerone, and zingiberenes, have been reported to have the ability to modify some biological activity. Compared to other chemicals, shogaol (18–25%) and gingerols (23–25%) are more prevalent. Besides, there are also proteins, minerals, water, phytosterols, raw fibre, ash, and some vitamins. The bioactive compound *Zingiber officinale* is illustrated in Fig. 18 [172].

Zingiber officinale contains gingerenone-A, quercetin, 6-dehydrogingerdione, and zingerone. Additionally, ginger contains a number of terpene components, including a-curcumene, a-farnesene, B-bisabolene, B-sesquiphellandrene, and zingiberene, which are considered to be the main components of ginger essential oil. The other several substances found in *Zingiber officinale* (ginger) are diarylheptanoids and the phenol gingerol. It has been used to treat nausea and vomiting caused by motion sickness and other conditions, and it might be somewhat effective [169].

There are several metabolites in ginger. However, the essential components are volatile; therefore, this plant is volatile when cooked or dried. Shogaol, gingerol, paradol, and zingerone are some of the non-volatile bioactive substances that are associated with their pharmacological effects. Regarding the presence of the B-hydroxy keto group, the gingerols (4-gingerol, 6-gingerol, 8-gingerol, and 10-gingerol) are thermolabile bioactive chemicals that are transformed to shogaols during the degradation of ginger, and shogaols can be hydrogenated into paradols. The pharmacological activities, pharmacokinetics, and bioavailability of both gingerol and shogaol compounds have many differences, with gingerol being more bioactive [169, 173].

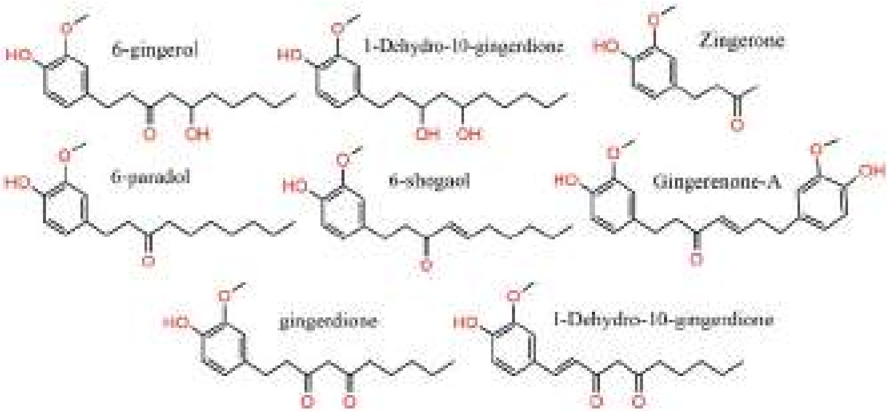

Fig. 18 Several bioactive compounds of ginger's rhizome. (Ishfaq et al. [172])

2.11.3 Usage as Chemoprevention

As one of the spices, and used for medical purposes, *Zingiber officinale* has been known for thousands of years for its usage [174]. Ginger has attracted a lot of attention from scientists due to its medicinal ability to control the activity of several enzymes. The herb has also been used to treat hypertension, dementia, helminthiasis, constipation, diarrhoea, toothaches, gingivitis, bronchitis, and asthmatic respiratory diseases, infectious diseases, anti-inflammatory, antioxidant, and cancer [175, 176]. Ginger has been shown through several previous studies to both block and treat a number of cancers as shown in Table 8. Also, the common mechanisms for anticancer involve the induction of apoptosis and the suppression of the proliferation of cancer cells [169].

Rhode et al. [177] reported that all of the cell lines examined experienced significant growth inhibition after being treated with ginger in cultured ovarian cancer cells. The study discovered that, among the individual ginger components examined in vitro, 6-shogaol is the most active. NF-kB activation was inhibited by ginger therapy, and VEGF and IL-8 secretion was also reduced. We conducted an experiment to evaluate the bioactivity of 6-, 8-, and 10-gingerol, as well as 6-shogaol, on A2780 ovarian cancer cells. The results showed that none of the three gingerols (6-, 8-, and 10-gingerol) had any impact on the viability of the ovarian cancer cells, while 6-shogaol can have a significant growth inhibition as seen in cells treated with whole ginger extract.

Ginger has demonstrated anticancer properties against colorectal cancer. It can prevent the growth and multiplication of colorectal cancer cells. In one study, 6-gingerol was found to halt the proliferation of colon cancer HCT116 cells. Additionally, it has been discovered that the reduction in tumour growth is associated with the activity of leukotriene A4 hydrolase, which was further supported by an in silico method [178].

Ginger extract with its components has been proven in preclinical tests to have chemopreventive and anticancer effects on gastric cancer. An in vitro study revealed

Table 8 The major pathways for anticancer activity of *Zingiber officinale*

Phytochemistry	Investigation type	Subjects	Treatment doses	Chemoprevention mechanism
6-Shogaol	In vitro	LNCaP, DU145, and PC-3 human prostate cancer cells	10, 20, and 40 μM	Inducing apoptosis; inhibiting STAT3 NF-kB signalling; downregulating the expression of cyclin D1, survivin, c-Myc, and Bcl2
6-Gingerol	In vitro	HeLa human cervical adenocarcinoma cells	60, 100, and 140 μM	Inducing cell cycle arrest in the G0/G1 phase; decreasing the levels of cyclin A, cyclin D1, and cyclin E1; increasing the expression of caspase; inhibiting the mTOR signalling pathway
10-Gingerol	In vitro	Human and mouse breast carcinoma cells	50, 100, and 200 μM	Inhibiting cell growth; reducing cell division; inducing S phase cell cycle arrest and apoptosis
6-Gingerol, 10 gingerol, 6-shogaol, and 10-shogaol	In vitro	PC-3 human prostate cancer cells	1, 10, and 100 μM	Inhibiting prostate cancer cell proliferation; downregulating the expression of MRP1 and GSTπ
Ginger extract	In vitro	HT29 human colorectal adenocarcinoma cells	2–10 mg/mL	Promoting apoptosis; upregulating the caspase 9 gene; downregulating KRAS; ERK; Akt; and Bcl-xL
	In vivo	Female Swiss albino mice	100 mg/kg	Activating AMPK; decreasing the expression of cyclin D1 and the level of NF-kB; increasing the expression of p53

Mao et al. [169]

that 6-gingerol induces apoptosis of gastric cancer cells. By boosting caspase-3/7 activation, it aids TNF-related apoptosis-inducing ligand (TRAIL)-induced apoptosis. By suppressing TRAIL-induced nuclear factor-kappaB (NF-κB) activity and downregulating the cytosolic inhibitor of apoptosis (cIAP)-1, 6-gingerol was able to cause apoptosis. In addition, 6-gingerol and 6-shogaol can decrease the growth of gastric cancer cells by harming microtubules [179].

Zerumbone is one of the ingredients in Asian ginger and also prevents the proliferation of pancreatic cancer through various mechanisms. According to the study, zerumbone induces apoptosis of PANC-1 cells. Reactive oxygen species (ROS) production and overexpression of the p53 and p21 proteins were linked to the induction of apoptosis in zerumbone-remedied PANC-1 cells [180–182]. This result suggests its induced apoptosis of PANC-1 cells via the p53 signalling pathway.

Studies conducted in vitro show that *Z. officinale*'s active ingredients help prevent liver cancer. According to a study, 6-shogaol has been revealed to induce apoptotic cell death of Mahlavu hepatoma cells through an oxidative stress-mediated caspase-dependent mechanism. 6-Shogaol-induced apoptosis of Mahlavu cells can be mediated by glutathione (GSH) depletion [183].

In addition, a number of additional pathways have been implicated in the reduction of cell growth by induced 6-gingerol and apoptosis in human colorectal cancer cells. These include downregulation of the NAG-1 beta-catenin, cyclin D1, PKCepsilon, and GSK-3β pathways, as well as protein degradation [184]. According to Radhakrishnan et al. [185], 6-gingerol's anticancer properties may be attributed to its ability to inhibit the ERK1/2/JNK/AP-1 pathway.

2.12 *Euphorbia abyssinica*

2.12.1 Taxonomy

Euphorbia abyssinica is the species of flowering plants which is well known for its therapeutic properties [186]. *Euphorbia abyssinica*, often known as desert candle, is a monoecious geophyte that can reach a height of 9 m as shown in Fig. 19 [187, 188].

Euphorbia abyssinica is a succulent, spiky tree with a height of up to 10 m. Its milky sap is poisonous. If the sap came into contact with the body, it would result in blistering, irritating dermatitis, keratoconjunctivitis, blindness, nausea, and vomiting. Euphorbon is a dangerous poison in plants that is found in many members of the Euphorbiaceae family [189].

Fig. 19 *Euphorbia abyssinica* plants

2.12.2 Phytochemistry

Euphorbia abyssinica was found to contain only low levels of diterpenes during chemical screening. In addition to euphorbol, euphol, oleanolic acid, lupeol, β-sitosterol, and β-sitosterol-3-O-glucoside, minor components such as ingenol esters and lathyrane derivatives have been reported in its latex. Moreover, the plant is composed of key ingredients such as rubber, waxes, and resins, and has demonstrated strong antifungal efficacy against *Aspergillus niger*, *Aspergillus flavus*, and *Candida albicans*, in addition to containing 8(R)-hydroxy-dec-3(E)-en-oic acid [190].

EL-Fiky et al. [190] have reported a new hydroxy unsaturated fatty acid called 8 (R)-hydroxy-dec-3(E)-en-oic acid isolated from biologically active components of *E. abyssinica,* and its chemical structure was fully determined. Four compounds were isolated and identified: lupeol, β-sitosterol, oleanolic acid, and β-sitosterol-3-O-glucoside.

In particular, ingenol and ingenol esters, which are tigliane-type diterpenoids, have shown promising activity against various types of cancer cells, making them a target of interest in drug discovery. Therefore, the identification and isolation of these diterpenes in Euphorbia species is important for their potential therapeutic applications primarily responsible for their antitumour activity [191].

2.12.3 Usage as Chemoprevention

Euphorbia abyssinica is actually believed to have traditional medicinal uses in Ethiopia for treating a variety of diseases, including ascariasis, gonorrhoea, leprosy, rabies, allergy (known locally as 'mitch'), toothache, syphilis, tinea infestation, TB, and skin cancer. These uses have been documented in ethnobotanical studies and suggest that the plant may have potential as a source of natural remedies. Plant latex and ground-up roots are pulverized as pastes or ointments to the affected area as a treatment for skin cancer. Meanwhile, there are no scientific findings related to the efficacy of this treatment for this particular species. The observations of two further similar species of *Euphorbia*, *E. tirucalli* and *E. prolifera*, have reported their usage as anticancer and antitumour treatments in traditional medicine outside of Ethiopia [192].

Furthermore, there have been numerous studies demonstrating various pharmacological activities of *Euphorbia* species. These activities include antiproliferative, cytotoxic effects, and antipyretic-analgesic effects [193]. El-Hawary et al. [194] reported that *Euphorbia abyssinica* has been shown to have cytotoxic activity against CACO2, which are human colon adenocarcinoma cells (IC50 11.3 μg/mL).

According to Ahmed et al. [195], both fruit and aerial parts are extracted from *Euphorbia abyssinica* by using ultra-performance liquid chromatography-mass of both extracts. In the DPPH experiment, the *E. abyssinica* spectrometry (UPLC-MS) revealed a rich source of a variety of ingredients. The identification and assessment of the antioxidant activity of 39 compounds were found in both aerial parts and fruit extracts of *E. abyssinica*. The fruit extract exhibited stronger antioxidant activity than the aerial part extract, as determined by three in vitro experiments with IC50 values of 85.1 ± 1.07 and 562.3 ± 1.01 g/mL, respectively. In addition, the study found that increasing concentrations of the *E. abyssinica* fruit extract triggered an increase in the protein expression of NQO1, a chemopreventive marker, in Hepa1c1c7 cells.

Emam et al. [196] revealed that 80% ethanolic extract of *E. abyssinica* was also cytotoxic and hindered the growth of cervical cancer cells (HeLa) by 55.2%. The ethanolic crude extracts of *E. abyssinica* exhibited 50% more growth or inhibition on HeLa cancer cells at a concentration of 30 μg/ml. In HeLa cancer cells, the IC_{50} value for crude extracts of *E. abyssinica* was 18.6 μg/ml. A strong cytotoxic activity was shown by *Euphorbia abyssinica*, but it was less potent than doxorubicin. *E. abyssinica* has a cytotoxic impact with an IC_{50} value of 18.6 μg/ml. The National Cancer Institute (NCI) defines an extract as potentially active against cancer cells if its IC_{50} value is $\leq$30 μg/mL. The IC_{50} value is the concentration of a substance needed to inhibit 50% of cell growth in vitro and is commonly used as a measure of cytotoxicity. Therefore, if a crude extract has an IC_{50} value of 30 μg/mL or lower, it is considered a promising candidate for further purification and investigation for anticancer activity.

2.13 *Kaempferia galanga*

2.13.1 Taxonomy

Kaempferia galanga is a pungent medicinal herb from a dried rhizome belonging to the family Zingiberaceae. The Zingiberaceae family consists of the stem-less herb, which belongs to the *Kaempferia* genus. In some places, it is also known as sand ginger or aromatic ginger [197]. *Kaempferia galanga* is a monocotyledonous plant in the Zingiberaceae family as shown in Fig. 20, which has roots and stems that are embedded in the ground [198, 199].

2.13.2 Phytochemistry

The chemical diversity of *K. galanga* is due to its ability to produce various secondary metabolites that are recognized to have a broad spectrum of biological functions. Terpenoids such as diterpenes, sesquiterpenes, and monoterpenes are the major components of *K. galanga*. Some of the identified terpenoids are sandaracopimaradiene-9α-ol, kaempulchraol I, and kaempulchraol L. Phenolic compounds such as galangin, kaempferol, and quercetin have also been identified in *K. galanga*. Anti-inflammatory, antioxidant, and anticancer properties are shared by these compounds. Moreover, cyclic dipeptides, diarylheptanoids, and polysaccharides have also been isolated from *K. galanga* and are known to possess various biological activities [200].

The essential oil extracted from the rhizomes of *Kaempferia galanga* L. was analysed using gas chromatography-mass spectrometry (GC-MS) method, and the major components of the oil were identified as borneol, ethyl cinnamate, ethyl-p-

Fig. 20 The rhizomes of *Kaempferia galanga* L.

methoxycinnamate, 8-cineole, γ-cadinene, 1, δ-carene, linoleoyl chloride, ethyl-m-methoxycinnamate, camphene, and α-pinene [201].

2.13.3 Usage as Chemoprevention

The main regions in Southern China where *K. galanga* is cultivated are Guangxi, Guangdong, and Yunnan. Because of its advantageous therapeutic effects on conditions such as inflammations and tumours, it was utilized as a folk remedy in China, which is a reservoir of valuable bioactive components. *K. galanga* was utilized in India to treat intestinal wounds and urticaria. Furthermore, it might be used as a food condiment [202, 203].

The rhizome of *Kaempferia galanga* is abundant in essential oils and a traditional remedy for indigestion, colds, chest and stomach pain, headaches, as well as an expectorant, diuretic, and carminative. Additionally, *K. galanga* extracts have anti-inflammatory, cytotoxic, antihypertensive, and hypolipidemic effects on the body, and are also used for the treatment of swelling [204].

Srivastava et al. [203] reported that the rhizome of *K. galanga* exhibits anti-proliferative properties, with EPMC being the primary phytochemical present in the rhizome. To investigate this further, the MTT assay was used to assess the anti-proliferative effects of the methanol extract, hydro-distillate, and EPMC on cancer cell lines specific to different organs. Cell growth has been seen to slow down in a dose-dependent manner. The highest concentration of EPMC, hydrodistillate, and extract (50 μg/mL) inhibited the proliferation of MDA-MB-231 cancer cells by 48%, 43%, and 36%, respectively. Similarly, the proliferation of WRL-68 cells was inhibited by EPMC, hydro-distillate, and extract at 50 μg/mL, with respective inhibitions of 37%, 42%, and 46%.

Hamid et al. [205] investigated the inhibitory effect of the extract of *Kaempferia galanga* L. on the expression of VEGF and Cox-2 in the chorioallantois membrane of embryonated chicken eggs (ECE). It was using 24 ECE and divided into six groups: C+, which was inoculated with solvent; C-, which was not inoculated; T1, T2, T3, and T4, which were inoculated with bFGF 60 ng and treated with extract dosages of 30, 60, 90, and celecoxib 60 mg, respectively. Besides, it was detected that the expression of VEGF and Cox-2 used the immunohistochemical method. The extract of *Kaempferia galanga* L. inhibited the expression of VEGF and Cox-2 in the chorioallantoic membrane as a result.

Swapana et al. [202] revealed that *Kaempferia galanga* exhibited good cytotoxicity against HeLa cervical cancer cell and HSC-2 mouth squamous cell carcinoma. The cytotoxicity was assessed using a modified MTT assay, and the IC50 values for sandaracopimaradiene-9α-ol, kaempulchraol I, and kaempulchraol L were found to be 75.1 μM, 74.2 μM, and 76.5 μM, respectively, against HeLa cervical cancer cell, and 69.9 μM, 53.3 μM, and 58.2 μM, respectively, against HSC-2 mouth squamous cell carcinoma.

According to the previous study, the essential oils extracted from *K. galanga* have shown some antitumour activity. To investigate their effects on MKN-45 cells, we evaluated the volatile oil's impact on cell cycle and apoptosis using flow cytometry (FCM). We treated the cells with different doses of volatile oil (1.56 g/d, 0.78 g/d, and 0.39 g/d) and found that the growth suppression rates of gastric cancer were 57.2%, 28.0%, and 5.0%, respectively. The high-dose volatile oil-treated group was the most effective, arresting the MKN-45 cells at G0/G1 phase and inhibiting their growth [206].

3 Conclusions

It is reported that natural compounds from traditional medicines, such as *Annona muricata, Curcuma longa*, *Curcuma xanthorrhiza, Curcuma zedoaria, Phyllanthus urinaria, Gynura procumbens, Garcinia mangostana, Morinda citrifolia*, *Nigella sativa*, *Moringa oleifera, Zingiber officinale*, *Euphorbia abyssinica,* and *Kaempferia galanga,* are useful for their potential chemopreventive properties. The research showed that they can act to inhibit cancer through various mechanisms to obstruct the proliferation and growth of cancer cells. Moreover, they can also help reduce oxidative stress and inflammation, which are the key factors in the development and the spread of cancer, induce apoptosis, or inhibit angiogenesis.

Abstract

Cancer is one of the high-profile diseases and is responsible for millions of deaths worldwide every year. Even though there are many therapeutic strategies (natural and chemical), many issue have been still unresolved in order to advance cancer therapy. For this, a lot of efforts are being put forwarded by oncology research to find new and efficient anticancer therapeutical strategies that can overcome the discomfort caused by conventional methods. Many of the chemically derived drugs and anticancer treatments already exist, but are known to have toxic effects. Hence, the demand for naturally derived anticancer agents is used as an alternative for which nature remains the main supplier, especially plants. Many plant-derived secondary metabolites, like alkaloids, brassinosteroids, flavonoids, polyphenols, and phytosterols, have potential as anticancer agents, unaided or in formulations, and have antioxidant activity, apoptosis induction, cancer cell line inhibition and cytotoxicity, multitarget specificity, etc. Many of these plant-derived drugs preexist in research and have been cleared for clinical trials, mostly in phases I–III. This chapter provides a thorough overview of the therapeutic drugs derived from plants and also advances a clinical assessment of recently investigated natural compounds in terms of their anticancer modes of action. Besides, some new technologies like nanococheleates, nanoparticles, and nanoliposomes are being used in the administration of anticancer therapies for target specificity. These plant-derived anticancer agents are in high demand as they are efficient inhibitors of cancer cells lines; hence, their exploration needs to be managed to be sustainable. These have the potential to minimize the harmful effects typically associated with conventional medicines. Unlike certain synthetic drugs, herbal medicines being derived from plant sources and may possess compounds that have a lower risk of toxicity or adverse reactions. Finally, the current review describes an in-depth analysis of the most innovative advances of several efficient therapeutic natural agents for the encapsulation and target specificity in basic and applied cancer research.

1 Introduction

Any region of the body can develop cancer, which is characterized by the unchecked growth and dissemination of abnormal cells. Cancer has the ability to infect nearby tissues and spread to the other organs. It is a complex disease influenced by various factors, including genetics and environmental exposures, certain lifestyle choices, etc., and is among the leading sources of death and mortality in humans. In spite of many advanced technologies, cancer deterrence is extremely superior to treatment and causes death of many patients during treatments. For treatment, early diagnosis (first stage) and removal of tumor by surgical resection and radiation therapy are among the most common methods. The positive chemopreventive results have increased the awareness among the people globally. Further, for chemoprevention, natural or synthetic compounds are used to prevent, suppress, or even reverse carcinogenesis as an alternative to simplify this frightening burden on public health [1]. Among these chemopreventive natural compounds, phytoconstituents are the most common as they show properties of preventive and suppressing agents [2]. Three major types of natural chemopreventive drugs, that is, natural products, semi-synthetic, and synthetic drugs, are derived from natural products [3]. The perusal of previous studies revealed that more that 25% of medical prescriptions for cancer patients dispensed contain active ingredients from plants [4, 5]. Nature harbors an immense repository of chemical compounds that have the potential to serve as valuable therapeutic agents. Many plants have a long history of traditional use in various medicinal systems, indicating their potential medicinal value. However, it is crucial to conduct systematic scientific investigations to identify and isolate bioactive compounds from these plants and evaluate their efficacy and safety. With advancements in technology and research methodologies, there are increasing opportunities for the discovery of novel anticancer drugs from natural sources. Exploration can involve screening a wider range of plant species, including those from diverse ecosystems and unexplored regions. Additionally, focusing on traditional medicinal systems and indigenous knowledge can provide valuable leads for identifying plants with anticancer potential [6]. However, unlike Western medicine system, traditional herbal medicine a mixture of many secondary metabolites and works on multiple signaling pathways and molecular targets [7, 8]. Therefore, using these medications may have a variety of benefits that may reduce toxicity, while others may boost bioavailability, maximizing their efficacy in improving health and well-being.

Since ancient times, natural products (NPs) and their derivatives have played a key role in pharmacotherapy for cancer and other infectious diseases owing to their phytoconstituents, which are changes with geographical and environmental distributions. Throughout history, various civilizations have relied on natural products as a source of medicine. Plants, fungi, marine organisms, and other natural sources have been extensively explored for their therapeutic potential. NPs are being employed to treat a great variety of ailments, including cancer and infectious diseases, due to the presence of bioactive compounds in them. NPs and their derivatives have been used in pharmacotherapy for cancer and other diseases for centuries [9]. The effectiveness of NPs in pharmacotherapy is attributed to their diverse phytoconstituents. Phytoconstituents are chemical compounds found in plants and other natural sources that possess medicinal properties. These compounds can include alkaloids, flavonoids, terpenoids, polyphenols, and many others. Different types of NPs contain unique combinations and concentrations of these phytoconstituents, which contribute to their therapeutic effects [9]. Importantly, the geographical and environmental factors under which NPs are grown or obtained can significantly impact the composition and concentration of their phytoconstituents. Plants and organisms in different regions exhibit variations in climate, soil composition, and other environmental factors, leading to distinct phytochemical profiles. This phenomenon is known as the chemical fingerprint of a natural product and contributes to the diversity and uniqueness of NPs obtained from different geographical locations. More than 60% of existing anticancer drugs have been derived from natural resources, which cover a significant portion of the world's population [10]. By harnessing the phytoconstituents present in NPs, researchers and medical professionals have been able to develop drugs and treatments for cancer and infectious diseases. Many successful anticancer drugs, such as paclitaxel derived from the Pacific yew tree, and antibiotics, such as penicillin derived from the *Penicillium* fungus, have been derived from natural sources. With increasing interest in herbal medicines globally, scientists are researching for functional or bioactive metabolites [11]. Recently, researchers are actively studying functional or bioactive metabolites found in NPs, such as curcumin, emodin, genistein, gingerol, kaempferol, quercetin, resveratrol, and tryptanthrin [12, 13]. These natural products (NPs) acquire early detection of the cancerous cells and also have many benefits, viz., easy availability, cost-effectiveness, no toxicity, multitargeting efficacy, drug resistance, and high potential for chemosensitization. Many studies have determined the importance of NPs and their effect reduces many chronic diseases. However, their use is inadequate because of their limited life span and low solubility [1]. So, this is the call of the hour, to look for the new curative strategies to overcome the current therapy resistance with more efficient, less toxic strategies, and more selectivity. Therefore, the NPs obtained from the natural resources and their uses in the development of novel molecular leads need to be broadly reviewed [14].

Despite the abundance of natural resources, only a small fraction of plants have been investigated for bioactive compounds. This necessitates further exploration of natural sources to discover novel anticancer drugs. Traditional herbal medicine, unlike the Western medicine system, consists of mixtures of secondary metabolites that work on multiple signaling pathways and molecular targets. This complexity may contribute to decreased toxicity and increased bioavailability of these medicines. Numerous clinical trials are currently underway to evaluate the efficacy of NPs as chemopreventive agents. Overall, the passage emphasizes the potential of natural compounds in cancer prevention and the need for further research and exploration to harness their benefits effectively. This chapter aims to collect data on active NPs as chemopreventive agents, including their current aspects, challenges, and future prospects for sustainable development. NPs have been used traditionally in various cultures for gastrointestinal diseases, analgesia, and anti-inflammatory purposes, and to promote overall health and vitality. Additionally, NPs are being used in numerous clinical trials as chemopreventive medications, which are covered in more detail later in this chapter.

2 Cancer: Etiology and Management Approaches

Most of the chronic diseases, cancer, cardiovascular, diabetes, etc., are most prevalent and costly to treat; however, these can be avoided through lifestyle changes. Among these, cancer is a growing public health problem globally, and in spite of costly chemotherapy treatments, it is estimated that cancer death rates could increase by 45% by 2030 [15]. The main reason for the increased cancer death may be low effectiveness of the present chemotherapeutic drugs as these are costly and also has some adverse side effects [15]. Hence, it is the call of the time to look for alternative nontoxic approaches and cost-effective methods, which also show some therapeutic resistance, effectiveness in preventing cancer resurgence, and improvement of life standards. Cancer shows a great deal of heterogeneity; despite this, transformation of a normal cell into precancerous lesion to malignant tumors by alternation in many signally pathways is among the common factor [16, 17]. The reason for such neoplastic transformation includes (i) exposure to UV, gamma, and X-ray radiations; (ii) infectious microorganisms (*Helicobacter pylori*, papilloma); and (iii) many carcinogenic agents [18, 19]. However, physiological anomalies like oxidant–antioxidants homeostasis, which, if get disrupted, results in more oxidants, and further leads to damaged DNA [20, 21] by imposing oxidative stress [22, 23]. Such oxidative damage to these macromolecules can lead to cancer development by inducing inflammatory signaling [24, 25].

3 Plant-Derived Drugs in Cancer Treatment

Cancer is among the leading sources of death and mortality in humans, and cases are constantly increasing, with changes in lifestyle or environment. Irrespective of the recent advance technologies, deterrence of cancer is extremely superior to treatment and causes the deaths of many patients during treatments. For treatment, early diagnosis (first stage) and removal of tumor by surgical resection and radiation therapy are among the most common methods. The positive chemopreventive results have increased the awareness among the people globally. Further, for chemoprevention, natural or synthetic compounds are used to prevent, suppress, or even reverse carcinogenesis as an alternative to simplify this frightening burden on public health [1]. Among these chemopreventive natural compounds, phytoconstituents are the most common as they show properties of preventive and suppressing agents [2]. These natural products (NPs) acquire early detection of the cancerous cells and also have many benefits, viz., easy availability, cost-effectiveness, no toxicity, multitargeting efficacy, drug resistance, and high potential for chemosensitization. The importance of NPs and their effect reduces many chronic diseases, which have been reported by many workers. Despite these benefits, the use of NPs is inadequate because of their limited life span and low solubility [1]. So, this is the call of the hour to look for the new curative strategies to overcome the current therapy resistance with more efficient, less toxic strategies, and more selectivity.

NPs and their derivatives have played a key role in pharmacotherapy for cancer and other infectious diseases owing to their phytoconstituents [9] for many years now, which are changes with geographical and environmental distributions. As reported previously, more than 60% of the existing chemopreventive drugs were obtained from natural resources [26], which covers over 80% of world's population [27]. With increasing interest in herbal medicines globally, scientists are researching for functional or bioactive metabolites [26, 27]. These include curcumin, emodin, genistein, gingerol, kaempferol, quercetin, resveratrol, tryptanthrin, etc. [1]. Therefore, the NPs obtained from the natural resources and their uses in the development of novel molecular leads have been/or need to be broadly reviewed [14]. So, the aim of this chapter is to collect data on active chemopreventive agents (NPs), current aspects, and challenges, and provide future prospects for sustainable development.

NPs are being used to cure many gastrointestinal diseases, such as analgesia, anti-inflammatory, increasing vitality, and sustain good health since ancient times in China, Egypt, India, and Mesopotamia [12, 13]. Natural chemopreventive drugs can be classified into three major types: natural products, semi-synthetic drugs, and synthetic drugs derived from natural products. Natural products are compounds directly derived from natural sources, such as plants, animals, or microorganisms. These compounds have a long history of use in traditional medicine and often exhibit diverse biological activities. Semi-synthetic drugs are derived from natural products but undergo chemical modifications to enhance their therapeutic properties. These modifications can improve drug stability, potency, or pharmacokinetics. Synthetic drugs derived from natural products are entirely synthetic compounds designed based on the chemical structure or pharmacophore of a natural product. These drugs aim to mimic or improve upon the bioactive properties of the natural compound while providing advantages such as increased potency or selectivity. By harnessing the wealth of natural compounds and employing chemical modifications or synthesis, scientists can develop a range of chemopreventive drugs with diverse structures and properties, offering promising avenues for cancer prevention and treatment [28]. Between 1980 and 2002, over 69% of the licensed anticancer medicines came from natural sources [29]. The perusal of previous studies revealed that more than 25% of medical prescriptions for cancer patients dispensed contain active ingredients derived from plants [4, 5] Despite the treasure of natural bounty, about 15% of the total plants have been reported with bioactive compounds so far [30], which leads to the need for more exploration of natural wealth in search of novel anticancer drugs [6, 7]. However, unlike Western medicine system, regarding their composition and mechanism of action targets, traditional herbal medicine is often a mixture of various secondary metabolites and can work on multiple signaling pathways and molecular targets [7, 8]. In contrast to natural chemopreventive drugs, which often utilize complex mixtures of compounds derived from natural sources, Western medicine tends to focus on isolated active compounds that target specific molecular pathways. Western medicine emphasizes the identification and isolation of individual active constituents from natural sources to understand their mechanisms of action and optimize their therapeutic effects. This reductionist approach allows for a more precise understanding of the specific components responsible for a drug's activity. The contrast between Western medicine's focus on isolated active compounds and the utilization of natural mixtures in natural chemopreventive drugs highlights different approaches to drug development. While Western medicine emphasizes targeted therapies and precise control, natural chemopreventive drugs often leverage the complexity and potential synergistic effects of natural sources. Both approaches have their merits and continue to contribute to the development of effective treatments for various health conditions. This characteristic of herbal medicine can potentially provide several functions, such as reducing toxicity and increasing bioavailability of active compounds. Several clinical trials using NPs as chemopreventive medicines are currently ongoing, which have been discussed later in this chapter.

4 Current Prospective

4.1 Plant Compounds with Medicinal Properties

Plants or plant-based medicines have been utilized for thousands of years by populations in Asia, Africa, and even developed countries as folk remedies or for health advantages. The WHO reports that many countries still rely on plant-based remedies as their primary source of medicine, which have shown to be effective for treating medical conditions [31, 32]. Many secondary metabolites/compounds have been identified and extracted from plants for their anticancer properties, which include alkaloids, phenolic compounds, and terpenoids (Table 1).

4.2 Phytosterol

These are the plant sterols frequently used in the human diet with unique properties of reducing cholesterol absorption in the gut. Medicinally, these are reported to weaken the inflammatory response of neutrophils and macrophages [32]. It has been linked to a number of positive health effects, including being an antioxidant and antipyretic, anti-inflammatory [107], treating benign prostatic hypertrophy, preventing breast cancer and colon cancer, reducing inflammation, protecting the liver, and treating rheumatoid arthritis [108]. The substance has previously been found in numerous plants, including *Vanda roxburghii* [109] and *Withania coagulans* [110]. Due to their potent therapeutic properties, they are thus a useful research topic. Some of these phytosterols like sulforaphane, obtained from broccoli, and Withaferin A, obtained from *Withania somnifera,* are summarized in Table 1.

Table 1 Natural chemopreventive compounds, their sources, and physiological targets

Preclinical uses of compound	Natural resource	Affected targets	References
Acetylbritaniilactone	*Inula britannica*	Decreases cyclin A, D1, E, and CDK2	[33]
Aclarubicin	*Streptomyces* sp.	Affects topo-isomerase-I and II	[34, 35]
Allyl sulfides	*Allium sativum*	Cell cycle arrest via mitochondrial signaling	[13, 36, 37]
Apigenin	Celery plant	Decreases cyclin A, D1, E and CDK2	[38]
Berberine	*Berberis* sp.	Increases CDKN1A and 1B	[39]
Betulinic acid	*Betula pubescens*	Inhibition of topo-isomerase, production of ROS	[40]
Bufotalin	*Venenum bufonis*	Degradation of CDC25A, CDK1	[41]
Butyrolactone −1	*Aspergillus terreus*	Inhibition of CCDK1/cyclin B complex	[42]
Capsaicin	Chili peppers	Cell cycle arrest and growth inhibition	[43]
Chebulagic acid	*Terminalia chebula*	Increases CDKN1B and decrease NF-kB	[44]
Combrestatin	*Combretum caffrum*	Inhibition of angiogenesis and microtubule depolymerization	[45, 46]
Curacin A and D	*Lyngbya majuscule*	Inhibition of tubulin polymerization	[47]
Curcumin	*Curcuma longa*	Increases ING4, CDKN1A, 1B	[48, 49]
Daunomycin	*Streptomyces peucetius*	Acts as intercalating agents	[26]
Diindolyl methane	Crussiferae	Prevention of tumor development (in vivo)	[50, 51]
Dineolignan	*Saurus chinensis*	Decreases CDK-6 and cyclin D	[52]
Discodermolide	*Discodermia dissoluta*	Acts as microtubules-stabilizing agents	[53]
Dolastanin 10 and 15	*Dolabella auricularia*	Prevents mitotic assembly	[54, 55]
Doxorubicitn	*Streptomyces peucetius*	Topoisomerase-II inhibitor	[26]
Epigallocatechin-3-gallate	Green tea	Increases CDK1A, 1B, 2A, and 2C	[56, 57]
Epothilone A, B, C D	*Sorangium cellulosum*	Mitotic arrest by stabilizing tubulins	[58, 59]
Fangchinoline	*Stephaniae moore*	Decreases cyclin A, D1, E	[60]
Flavopiridol	*Dysoxylum binectariferum*	Tyrosine kinase inhibitor, cell cycle arrest; apoptotic induction	[61, 62]
Indole-3-carbinol	Brassicaeae family	Decreases CDK-2, cyclins D1	[63]

(continued)

Table 1 (continued)

Preclinical uses of compound	Natural resource	Affected targets	References
Isorhamnetin	*Hippophae rhamnoides*	Increases CDKN1A	[64]
Limonoids	Oranges and lemons	Apoptotic induction`	[65, 66]
Myricetin	*Myrica cerifera*	Inhibition of matrix metalloproteinase	[67, 68]
Pacilitaxel	*Taxus brevifolia*	Stabilizes tubulin polymers	[69, 70]
Palmatine	*Berberis lyceum*	Increases CHEK2 and decreases CDC25	[71]
Phloridzin	Apple	Increased expression of tyrosinase genes	[72]
Podophyllotoxin	*Podophyllum peltatum*	Causes ss-DNA and ds-DNA breaks	[73, 74]
Proanthocyanidins	*Vitis vinifera*	Decreases CDK-1, 4, and 6	[75, 76]
Pseudolaric acid B	*Pseudolarix kaempferi*	Decreases CDC2 and 25	[77]
Quercetin	*Quercus* spp.	Reduced proliferation and angiogenesis	[78, 79]
Retinoic acid	*Dacus carrota*	Decreases telomerase activity	[80, 81]
Rhizoxin	*Rhizopus chinensis*	β-Tubulin binding	[82, 83]
Rocaglaminde-A	Aglaia	Degradation of CDC25A, induces ATM pathway	[84]
Roscovitine	Radish	Inhibition of cyclin-dependent kinases (CDKs)	[85, 86]
Rosamultic acid	*Rosa multiflora*	Decreases CDK4, 6 and cyclin D1	[87]
Sanguinarine	*Papaver somniferum*	Apoptotic induction and caspase activation	[88, 89]
Silibinin	*Silybum marianum*	Regulation of tumor necrosis factors, decreases CDK2`	[90–92]
Spongistanin 1	*Hyrtios erecta*	Binds to the site on β-tubulin	[93]
Sqamocin	*Annonaceous* sp.	Increases CDKN1A and 1B	[94]
Sulforaphane	Broccoli	Inhibition of viability and in vitro proliferation	[95, 96]
Tamarixetin	*Tamarix ramosissima*	Increases cyclin B1, BUB1, and CDKN1A	[97]
Tanshinone IIA	*Salvia miltiorrizae*	Decreases CDC-2	[98]
Theaflavin	Black tea	Apoptotic induction via Fas/ caspase-8 and Akt/pBadu	[99, 100]
Tryptoquivaline	*Aspergillus fumigatus*	Inhibits MAP2, Tau-induced tubulins	[101]
Vinblastine	*Catharanthus roseus*	Inhibits tubulin polymerization	[102, 103]

(continued)

Table 1 (continued)

Preclinical uses of compound	Natural resource	Affected targets	References
Vincristine	*Catharanthus roseus*	Inhibits tubulin polymerization	[102, 103]
Withaferin A	*Withania somnifera*	Targeting on Hsp90, cell cycle arrest	[104]
Wogonin	*Scutellaria radix*	Decreases cyclin A, D1, E	[105]
Zerumbone	*Zingiber zerumbet*	Decreases cyclin B1 and CDKs	[106]

4.3 Phenolic Compounds

The phenolic compounds are the most commonly occurring secondary metabolites, which are the products of pentose phosphate, phenylpropanoid, and shikimate pathways in plants [111]. Besides their medicinal importance and protection against pathogens, these compounds positively affect growth and reproduction of plants also [112]. Additionally, like most of the allied compounds, it also shows antioxidant, anti-inflammatory, and anticancerous properties [113]. The caffeic acid is a well-known phenolic compound and is popularly known for reducing the level of cholesterol, free fatty acids, phospholipids, and triglycerides in rats [114], and also can reduce the chances of skin cancer. The compound is also known to be dispersed in many fruits and vegetables. This compound is also detected from various other plants, such as *Origanum vulgare* and *Ocimum gratissimum* [115]. Chlorogenic acid, which is created through the esterification of cinnamic acids like caffeic acid and quinic acid, is another member of the phenolic chemical family. Some of the phenonic compounds, such as apigenin, combrestanin, flopiradiol, indole-3-carbinol, isorhamnetin, myricetin, phloridizin, quercitin, retinoic acid, rhizoxin, tamarixetin, and wogonin, along with their physiological role, are summarized in Table 1.

4.4 Alkaloids

Alkaloids, a group of naturally occurring organic compounds, are characterized by their alkaline properties and are typically found in various parts of the plants, such as leaves, stems, roots, and seeds. Alkaloids exhibit a wide range of chemical structures and biological activities and are medicinally important as effects on the human body, ranging from pain relief and stimulant properties to toxicity. Some well-known alkaloids include caffeine, cocaine, morphine, nicotine, quinine, and strychnine. Few famous alkaloids, like berberine, capsaicin, curacin A and fangchinoline, paclitaxel, palmatine, rosamultic acid, sanguinarine, vinblastine, and vincristine, are of plant origin and known for their anticancerous properties. The details of these compounds, along with the natural resources and their physiological targets, are discussed in Table 1.

4.5 Triterpenoids

These are also a group of secondary metabolites produced by pentacyclic triterpenoids (betulinic acid), which show direct or indirect antioxidant properties that are beneficiary to the cardiovascular disease [116]. Betulinic acid is a naturally occurring triterpenoid and widely dispersed throughout the plant kingdom, especially in *Betula* spp. [117], where it was reported for the first time in the species *B. alba* [117]. It exhibits a variety of medicinal properties and biological activities, such as inhibition of HIV [118], antibacterial [119], and also anticancer activities [120]. Another naturally occurring pentacyclic triterpenoid, named oleanolic acid, is prevalent in the members of Oleaceae family, especially in the species *Olea europaea*, after which the compound was named, and is still a main source (commercial) of the compound [121]. After this, the compound has been isolated in about 1620 plants, which are highly known for their food and medicinal properties [122]. In the plants, oleanolic acid is reported in cuticles with waxes, helps plants in excessive water loss, and also as defense line against the pathogens, for example, fungal pathogens [123] or other allelopathic agents [123]. Another naturally occurring triterpenoid, ursolic acid, is a secondary metabolite of the plants and usually occurs in the stem bark, fruit peels, and even in leaves [124]. The perusal of the literature reveals a number of medicinal and pharmacological properties. The compound is also reported with a number of anticancerous activities [124], antimalarial activity, and antibacterial activities [125] as it affects the peptidoglycan metabolism. Many other triterpenoids, for example, zerumbone, a monocyclic sesquiterpene, are obtained from *Zingiber officinale* and are known for their anticancerous properties as they decrease cyclin B1 and CDKs (Table 1). Similarly, pseudolaric acid B, obtained from *Pseudolarix kaempferi*, is known to decrease cdc2 and cdc25 (Table 1).

4.5.1 Brassinosteroids (BRs)

Brassinosteroids (BRs) are another group of plant hormones that have been investigated for their potential chemopreventive properties. Chemoprevention refers to the use of natural or synthetic substances to prevent, inhibit, or reverse the development of cancer [126]. Here are some ways in which brassinosteroids may play a role as chemopreventive herbal medicine [127]:

1. Antioxidant and anti-inflammatory effects: Brassinosteroids possess antioxidant properties and can reduce inflammation. These effects are important in chemoprevention since chronic inflammation and oxidative stress are known to contribute to the development and progression of cancer. By reducing inflammation and neutralizing free radicals, brassinosteroids may help protect cells from DNA damage and inhibit the formation of cancerous cells.
2. Cell cycle regulation: Brassinosteroids have been found to influence the cell cycle progression and cell division in various cell types. Abnormal cell cycle regulation is a hallmark of cancer, and compounds that can restore or modulate the cell cycle have potential as chemopreventive agents. Brassinosteroids may help maintain proper cell cycle control, preventing the uncontrolled proliferation of cancer cells.

3. Apoptosis induction: Apoptosis, or programmed cell death, is a natural process that eliminates damaged or potentially cancerous cells. Dysregulation of apoptosis can contribute to tumor formation and growth. Some studies have suggested that brassinosteroids can induce apoptosis in cancer cells, promoting their programmed death. This property is crucial in eliminating cancer cells before they become clinically significant.
4. Immune modulation: The immune system plays a critical role in recognizing and eliminating cancer cells. Brassinosteroids have been shown to modulate immune responses by regulating the activity of immune cells, such as T cells, natural killer (NK) cells, and macrophages. By enhancing immune surveillance and promoting immune cell activity, brassinosteroids may aid in the prevention and control of cancer.
5. Antiangiogenic effects: Tumor growth relies on the formation of new blood vessels, a process known as angiogenesis. Inhibiting angiogenesis can limit tumor growth and metastasis. Some studies have suggested that brassinosteroids can suppress angiogenesis by inhibiting the production of pro-angiogenic factors. This antiangiogenic property may help prevent the development and spread of cancer.

It is important to note that the research on brassinosteroids as chemopreventive agents is still in its early stages, and further studies are needed to validate their effectiveness and safety. Additionally, the optimal dosage, delivery methods, and potential interactions with other medications need to be determined. Two natural BRs, 28-homocastasterone and 24-epibrassinolide, have been observed with anticancer effects [127].

4.6 Plant-Derived Anticancer Drugs

Drugs derived from plants are preferred in cancer treatment owing their natural origin, easy availability, and the potential for administration as part of dietary intake [128, 129]. Normally, these plant-derived drugs are generally nontoxic to human cells [130], although there are some such as cyanogenetic glycosides, lectins, lignans, saponins, and some taxanes [130, 131]. Plant-derived drugs can be classified into four classes: methyltransferase inhibitors, DNA damage preventive drugs or antioxidants, histone deacetylases (HDAC) inhibitors, and mitotic disruptors [128]. These classes target specific molecules or pathways involved in cancer cell growth and proliferation. These compounds have been discussed in Table 1 with names of the compound, natural resource, and affected targets. The plant secondary metabolites, such as isoflavones, isothiocyanates, pomiferin, and sulforaphane, are considered to be histone deacetylases inhibitors that inhibit carcinogenic proteins [127]. Further, derivatives of vinca alkaloids, vinblastine, vincristine, vindesine, vinflunine, and vinorelbine also inhibit the binding to β-tubulin in microtubules [132]. Similarly, taxanes (paclitaxel and its analog docetaxel) act as microtubule disruptors and inhibit cell-causing cell cycle arrest and apoptosis [133, 134]. Paclitaxel was one of the first drugs to be observed with massive implication for cancer treatment, while vinblastine and vincristine were among the first medications to be separated [132]. Table 1 provides a list of various compounds derived from natural resources and their preclinical uses in cancer research. These compounds target specific molecules or pathways involved in cancer cell growth and proliferation.

5 Challenges of Anticancer Phytochemicals

Anticancer phytochemicals face several challenges in their development and application. The developments of plant-derived anticancer agents for clinical trials require significant evidence of efficacy before approval for use in patients. In spite of the significant anticancer properties of NPs, it needs to be checked prior to clinical application. So, absorption, poor aqueous solubility, inadequate therapeutic potential, poor penetration in target cells, and toxicity are some of the characteristics that still are of major concern before applying these compounds in the clinical treatment of cancer [135, 136]. For example, compounds like camptothecin, colchicine, and podophyllotoxin, and their derivatives are in limited use due to side effects. Some others, like vinca alkaloids, are being used in formulations as they show limited effect singly. Another challenge is their limited bioavailability as they may be poorly absorbed and distributed in the body, reducing their effectiveness of reaching cancer cells. The complex mixture and variability of phytochemicals from different plant sources make standardization difficult, hindering consistent efficacy and safety. Moreover, the lack of specific targeting may result in off-target effects and potential toxicity. Interactions with other drugs and therapies, as well as the presence of side effects, need to be carefully managed. Additionally, the limited clinical evidence and the absence of intellectual property protection pose hurdles for commercialization and investment in research. Overcoming these challenges requires extensive research, robust clinical trials, interdisciplinary collaboration, and regulatory support to harness the full potential of phytochemicals in the fight against cancer. Beside these challenges, clinically tested phytochemical compounds also face challenges like characterization, extraction, optimization, and synthesis of anticancer compounds. Thus, new advances are required in analytical and computational methodologies to ease the process of identification, optimization, synthesis, and modification of new phytochemicals.

5.1 Low Solubility and Absorption

As discussed in the previous section, the phytochemical compounds are limited in availability and also have lower potential in cancer treatment. To solve this issue, lipid-based formulations and nanotechnology have been used to enhance bioavailability, solubility, and target specificity of these compounds [136, 137]. It mentions specific examples, like the encapsulation of vinca alkaloids and paclitaxel in liposomes and other nanoformulations to improve their therapeutic efficacy. However, it also noted that while many nanomedicines have been investigated, only a few have progressed to clinical trials, and even fewer have been cleared for clinical application [138]. This encapsulation enhances performance by controlling release and also providing protection for the bioactivity against external environment. For example, liposomes, such as Marqibo®, have been cleared by the FDA for the treatment of adult leukemia [139]. Similar efforts have also been done for paclitaxel, resulting in the development of various nanoformulations, including polymeric nanoparticles, polymeric conjugates, polymeric micelles, and liposomes [138]. However, despite the extensive investigation of nanomedicines, only a few formulations have progressed to clinical trials, and even fewer have been approved for clinical application. For instance, a hydroxypropyl-methacrylamide copolymer–paclitaxel formulation developed by Pfizer was discontinued in phase I due to high neurotoxicity observed in rats. Poly (L-glutamic acid)-paclitaxel is one of the few formulations to reach phase III of clinical trials but was ultimately discontinued in 2016 because it did not demonstrate significant results over the current standard [140]. In case of irinotecan, its hydrophobic nature, low stability at physiological pH, and side effects limited its therapeutic use. To address these limitations, new drug formulations incorporating nanoparticles with carbohydrates, dendrimers, peptides, and polymer conjugates have been investigated [141].

Similar challenges have been posed by low solubility and availability of certain compounds in clinical application, which limits their potential for cancer treatment. Resveratrol, for example, has a short circulation life of a few minutes, while quercetin works at low concentrations in the blood, which is insufficient for effective anticancer activity [142]. To address these limitations, many studies have explored innovative strategies to increase the availability of these compounds. These strategies include the development of liposomes, nanoformulations, nanoparticles, and other delivery systems. For instance, gingerol in combination with proliposomes increases in vitro inhibition of HepG2 cancer cells and also improves oral bioavailability in vivo [143]. In another study, nanoparticles of gold-coated iron oxide significantly improve the activity and stability of SFN (sulforaphane) against human breast cancer cells. Furthermore, mesoporous silica nanoparticles formulated with hyaluronic acid have been used for the delivery of curcumin [144]. The anticancer activity of curcumin was evaluated in both in vitro and in vivo experiments, and the results revealed enhanced the anticancer activity, potentially due to improved bioavailability. These examples highlight the potential of innovative strategies and nanotechnology-based formulations in enhancing the availability and effectiveness of compounds in clinical applications. By improving solubility, stability, and bioavailability, these approaches aim to overcome the limitations that hinder the therapeutic use of such phytoconstituents in cancer treatment [145].

Nowadays, many clinical trials are exploring modern strategies to improve the bioavailability of these chemotherapeutic drugs, but the number of these studies is relatively limited compared to the extensive research published on novel strategies [137, 140]. This indicates that there is still a gap between preclinical research and clinical implementation in this field. As the understanding of drug delivery systems, nanoformulations, and other innovative strategies continues to advance, there is a growing interest in translating these findings into clinical applications. The need to improve the bioavailability and efficacy of these chemotherapeutic drugs remains a critical goal in cancer treatment.

5.2 Phytochemicals in Combination with Conventional Chemotherapeutics

The previous studies of phytochemical drugs revealed that single-target chemical agents are inefficient in cancer treatment owing to rapid molecular adaptations of cancer cells, and their limited effects, when used alone [145]. As a result, a combinatorial approach involving amalgamation of phytochemicals with conventional chemotherapeutic drugs proposes to achieve synergistic effects, increase toxicity in cancer cells, reduce therapeutic doses, and address toxicity concerns. Numerous studies have been conducted to evaluate the efficacy of these combinatorial approaches [146–148]. Resveratrol is a successful example of these drugs and used in vitro and in animal models as an adjuvant with other drugs, like doxorubicin, paclitaxel, and temozolomide. Similarly, curcumin has been employed as a chemosensitizing agent in combination with cisplatin, docetaxel, irinotecan, paclitaxel, and vincristine, leading to decreased drug resistance and enhanced efficacy compared to single treatments [133, 149, 150]. Other phytochemicals such as apigenin, berberine, betulinic acid, and gingerol have also been evaluated in combinatory assays to enhance the sensitivity of cancer cells to chemotherapeutic drugs. Clinical trials have also explored the combination strategy, as indicated in Table 1. Although more studies are still needed, the use of phytochemicals as chemosensitizers shows promise in cancer therapy. By combining them with conventional chemotherapeutics, it may be possible to overcome drug resistance, enhance therapeutic efficacy, and reduce the overall toxicity associated with higher drug doses.

6 Future Sustainable Development

Chemopreventive herbal medicine is poised to play a crucial role in future sustainable development. As the world seeks more sustainable solutions in healthcare, herbal medicine offers a natural and eco-friendly approach. By harnessing the healing properties of plants, it reduces reliance on synthetic drugs, minimizing their environmental and social impacts. Furthermore, the cultivation and sustainable harvesting of medicinal plants promote biodiversity conservation and support local economies, particularly in rural communities. Integrating traditional knowledge systems and personalized preventive healthcare approaches can lead to a more holistic and culturally sensitive healthcare system. Embracing chemopreventive herbal medicine can pave the way for a sustainable future where human health, environmental preservation, and socioeconomic well-being are all interconnected and mutually beneficial.

6.1 Enhancing Drug Administration

With the advancement and emergence of naturally derived drugs, new technologies are/or being developed using these anticancer compounds. The combination of these plant-based drugs, viz. combination of alkaloids, diterpenes, and lignans in plant extracts, is reported with some enhanced anticancer properties and also reported with improved therapeutic efficacy [132, 134]. For example, extracts of *Artemesia monosperma*, *Origanum dayi*, and *Urtica membranaceae*, in combination, were tested on cancer cell lines [134], and the results revealed killing effect on cancer cells; however, normal human lymphocytes and fibroblasts were not affected. Further, these drugs were known to induce apoptosis by increasing sub-G_1 phase populations with lower content of DNA and condensed chromatin, and also increase caspase-3 activation [134]. As a result, plant products are more widely used as medicinal agents than those made of hazardous chemicals, and more clinical trials should take these factors into account.

Further, for the effective administration of new drugs (natural compounds), they need to be a perfect alteration to the modern treatments, such as chemotherapy. This can be attained by developing nanoparticles, which act as delivery system in drugs to reach the target sites. The anticancer natural compound is limited in the clinical because of the high dosages if applied separately, but shows great result if applied in combination with nanoparticles [133]. Bromleain, a proteolytic compound, isolated from *Aanas comosus*, is more effective in cancer treatment in combination with nanoparticles than free [133]. These bromelain-loaded NPs trigger apoptosis in benign cells by regulating the proapoptotic expression and antiapoptotic proteins. Similarly, gold nanoparticles in formulation with *Antigono leptopus* extract (powdered) and copper oxide nanoparticles of *Acalypha indica* showed cytotoxic effect against MCF-7 cell lines of breast cancer [149]. Paclitaxel, a natural compound from *Taxus* spp. (gymnosperms), has been cleared for clinical trials and early treatment settings. However, modern researchers are aiming to use magnetic mesoporous silica nanoparticles to control the drug release and enhance target specificity [150], so that paclitaxel can be controlled externally. Success was also reported in another drug, quercitin, where formulation with superparamagnetic magnetite nanoparticles was tested against MCF-7 cell lines of breast cancer [151]. This procedure has been successful in increasing the drug's capacity to stop the spread of cancer as well as lower undesirable effects [150]. Additionally, nanocochleates and nanoliposomes are being used by researchers in anticancer activities [151] by oral or inhalable ingestion, which is more comfortable and economical. Additionally, clinical trials with noscapine, a benzylisoquinoline alkaloid derived from the poppy plant, were constrained by its intractable characteristics [152]. The formulation of nanoliposomes with 9-bromo-noscapine and its subsequent increase in cytotoxicity and apoptosis in lung cancer cell lines compared to the free compound is an exciting development. The use of nanoparticles in cancer treatment has gained significant interest and is showing promising results as a natural alternative to conventional chemotherapy. Nanoparticles, such as liposomes, can improve the delivery of therapeutic agents to cancer cells, enhancing their efficacy while minimizing side effects.

The small size and unique properties of nanoparticles allow them to selectively target tumor cells, penetrate cellular barriers, and release the drug payload efficiently. This targeted approach increases the concentration of the therapeutic agent at the site of the tumor, leading to enhanced cytotoxicity and apoptosis. The application of nanoliposomes as a delivery system for 9-bromo-noscapine demonstrates the potential of nanoparticles in improving cancer treatment outcomes, offering a more targeted and effective approach that may reduce the toxicities associated with traditional chemotherapy.

6.2 Medicinal Plant Demands

Due to the cytotoxic impact they have on cancer cells and lack of toxicity on healthy cells, plant-derived medicines have undergone a number of effective clinical trials and are now widely used and in great demand for clinical development. A lot of species have been investigated globally (especially in developing countries) where medicinal plants are used and herbal therapies are practiced for primary treatment [153–155]. A WHO report estimated that the trade value of plant-derived drugs was US$100 billion in 2007, which was anticipated to reach US$5 trillion by 2050 [127]. This huge demand for plant-based drugs in developing countries is putting pressure on the floral diversity and increase the threat of extinction of these plants of this overexploitation of floral diversity continues. Normally, when these plants are harvested, only a part of the plant (bark, leaf, bulbils, tuber, etc.) is used, which may threat its survival to extinction [156]. So, to increase the sustainability of medicinal plants these countries, conservation of these plants is vital and also the use of all plant parts including bark, leaf, stem, and root should also be included in the exactions of bioactive compounds and also in treatment (if applied directly). Other conservation methods are storing viable seeds, cryopreservation, germplasm conservation, tissue culture, etc. [157, 158], which allows industrial utilization the medicinal plants [158]. Besides the developing nations, cultivation practices of these plants are undergoing even in developed nations to meet with increasing demands of natural drugs [156]. These cultivation practices may release pressure on floral diversity. Recently, most attention is drawn toward the fruit berries and crucifer vegetables [159]. Nowadays, industrial raw products with anticancer properties like grapes and grapes seed extract are being added in food stuffs due to the high polyphenolic content. In wine industry, grape stems are used as raw by-product of wine making; however, waste may be used for anticancer drug development due to its high polyphenolic content and antioxidant properties. The utilization of industrial waste from medicinal plants can indeed present a profitable scheme to address environmental issues while harnessing their medicinal properties. Industrial waste from medicinal plants often contains valuable bioactive compounds that can be extracted and utilized for various purposes. By repurposing and recycling this waste, we can reduce environmental pollution and contribute to a more sustainable and circular economy. Furthermore, the bioactive compounds present in these plant waste materials may have therapeutic potential. For example, the utilization of waste-derived compounds in the prevention of DNA damage by alleviating oxidative stress is a promising application [160]. Oxidative stress is known to contribute to various health conditions, including cancer. By utilizing these waste-derived compounds, we can potentially develop natural antioxidants that can help protect DNA from damage and promote overall cellular health. Additionally, the anticarcinogenic potential of waste-derived compounds against specific types of cancer, such as cervical cancer and thyroid cancer, is encouraging. Research studies exploring the anticancer properties of these compounds can lead to the development of specific treatments or preventative measures for these cancers. This not only contributes to the field of cancer research but also highlights the value of utilizing waste materials from medicinal plants in addressing significant health concerns. In summary, the utilization of industrial waste from medicinal plants offers a dual benefit of addressing environmental issues while capitalizing on their medicinal properties. By repurposing waste materials, we can contribute to a more sustainable and environmentally friendly approach, while simultaneously exploring their therapeutic potential for various health conditions, including cancer prevention and treatment [160, 161].

7 Conclusion

Cancer is one of the high-profile diseases globally and millions of people died from cancer or related diseases in low-income countries [160]. As a result, there is a huge market for its prevention and treatment. Numerous chemically generated medications and anticancer therapies currently exist [162], but they are known to have deleterious effects on tissues that are not their intended targets, leading to a variety of health problems. Therefore, there is a demand for naturally derived anticancer agents as an alternative. Many plant secondary metabolites, such as alkaloids, brassinosteroids, flavonoids, polyphenols, and phytosterols, have been studied for their potential use as anticancer agents (collectively) with antioxidant activity, apoptosis induction, cancer cell line inhibition and cytotoxicity, multitarget specificity, etc. (Table 1). Many of these plant-derived medications have entered clinical trials after being utilized in research. (Table 1), mostly in phase I to phase III (vinca alkaloids and paclitaxel). These compounds are easily available naturally and possess cytotoxicity to cancer cells, while relatively no effect on normal cell. Besides, some new technologies like nanocochleates, nanoparticles, and nanoliposomes are being used in the administration of anticancer therapies for target specificity. These formulations can be used to control prolonged drug release and support efforts to develop novel, target-specific medications with fewer severe side effects. However, the floral biodiversity is in danger, especially in emerging nations, due to the rising demand for these plant-derived medicines made from valuable, endangered, or uncommon medicinal plants [156]. This load on floral biodiversity and shortage of utilizing raw by-products in industries can be overcome by adopting conservation strategies [157, 161]. The high demand for plant-derived anticancer agents due to their efficiency in inhibiting cancer cell lines highlights the need for sustainable exploration and management of these resources. Sustainable management involves various aspects, such as conservation of medicinal plants, responsible harvesting practices, and promoting cultivation or farming of these plants. It is important to identify and prioritize plant species that have demonstrated potent anticancer properties and work toward their sustainable production and utilization. This includes implementing regulations and guidelines for wild harvesting, promoting organic farming practices, and supporting local communities engaged in the cultivation of medicinal plants. Additionally, research efforts should focus on identifying alternative sources or sustainable synthesis methods for these anticancer agents to reduce reliance on wild harvesting. By managing the exploration of plant-derived anticancer agents in a sustainable manner, we can ensure their availability for future generations and contribute to the long-term viability of these valuable natural resources.

Abstract

The socioeconomic, spiritual, and cultural importance of traditional medicine resonates well with majority of Sierra Leonean who use traditional medicine for healing and income purposes. This chapter discusses the traditional medicines status, opportunities in Sierra Leone and proffer remedies for traditional medicine dosage, challenges, misconception, and the sustainability of traditional medicines for the socioeconomic development of Sierra Leone. It is also believed that traditional healing powers inherited by native Doctors are mostly associated with spiritual powers from ancestral spirits. The sources of traditional medicine range from plant roots, leaves, fruits, animal parts, insects, rodents, birds, among others. Although some plants are prepared by macerating plant leaves in either cold or hot water, others plant parts like the leaves and barks are pounded, sieved, and water added to prepared the infusion for ingesting. Plant parts are in some instance burned to ashes and applied to cure rare illness. Study revealed that traditional medicines are used to cure sicknesses such as malaria, fever, bone fracture, demons, stomach ache, dysentery, piles, among other sicknesses, in Sierra Leone. Two recognized categories of traditional healers are known in Sierra Leone; they are traditional birth attendant and traditional healers commonly known as herbalist. However, the processing of most traditional medicines is complex and complicated. The study concludes that traditional medicines have been contributing to the socioeconomic development of hard to reach communities across Sierra Leone since the precolonial era. This has enabled most herbalist to gained self-employment and recognition through traditional medication and treatment. Nonetheless, traditional knowledge on forests medicines is being threatened by technological advancement and modern civilization in Sierra Leone. In such, the future direction of traditional medicine and its sustainability in Sierra Leone is uncertain due mainly to technological advancement, population growth, and climate change.

1 Introduction

Traditional medicine's socioeconomic, spiritual, and cultural importance resonates well with majority of Sierra Leonean especially the elderly who are residing in rural communities. The spiralling significance of traditional medicine in tackling various illnesses in rural and hard to reach societies of developing countries especially in Africa cannot be over emphasized [1]. From ancient times, herbal medicines derived from plants in the wild has been useful in treating diverse types of diseases and illnesses hence alleviating poverty and pain in rural societies. It is undeniable over the past centuries that, traditional medicines in Africa has played a pivotal role in the maintenance of basic health system especially in locally deprived communities [2, 3]. For centuries now, natural plant resources have been a critical resource for the maintenance of basic healthcare in mostly deprived communities on the planet since time immemorial [4]. Globally, Traditional Medicine (TM) has been referred to as native medicine; ethnomedicine; local medicine; folk medicine among other names and is the oldest health therapy in Africa [5]. Traditional medicine has been widely used across Africa for the treatment of various types of illnesses long before the arrival of orthodox western medicines [6]. Traditional medicine is the combined knowledge and skill used by traditional people based on their beliefs, norms used to cure and maintain good health in local communities. Before the colonial era and the arrival of cosmopolitan medicine into Africa, traditional medicine was the sole source of medical treatment accessible in urban and rural societies across Sierra Leone [5].

These medicines are also used to cure physical and mental illnesses as well as diagnose and treat spiritual encounters [7, 8]. Traditional medicines have served as an alternative health remedy for majority of African populations especially in rural communities. Traditional medicines comprise diverse chemical substances capable of healing various diseases [9]. According to WHO estimate, 80% of the global population uses traditional medicines as indigenous therapies to cure many sicknesses [10]. It is reported that over 170 countries used traditional medicine as a supplement to expensive orthodox medicine. From time immemorial, traditional medicine is considered an integral resource used to cure diseases in communities without conventional medical facilities. Traditional medicine has been and is still considered a mainstay of traditional people's health [10] especially in developing countries like Sierra Leone.

Across Africa, traditional medicines are not considered a substandard medicine to conventional drugs, but instead used as an alternative for locals without access to hospitals and other health facilities [11]. Traditional medicines especially in developing countries is used to treat fungal and other skin diseases that have proven to be complex for Western drugs [12, 13]. Moreover, traditional medicines are relatively cheap as compared to Western medicines that are expensive and mostly unreachable in some developing countries like Sierra Leone. Globally, traditional medicine has gained momentum and is considered a trillion-dollar health remedies, healthy living and industries for cheap pharmaceuticals products [10]. Traditional medicines are sources of artemisinin and aspirin drugs but the actual importance of these medicines is understated [10]. These drugs extracted from traditional medicines are used to cure various sicknesses such as diarrhea, skin rash, bone fracture, wounds, etc. [14, 15].

Traditional medicines are a critical source of health therapies in deprived rural communities across Africa and Sierra Leone in particular. In most societies of developing countries, traditional healers are labeled as native doctors due to the fact that they play an important spiritual, cultural, and ancestral mouthpiece role for communities without good health facilities. According to Clarke, [16] and Semenya and Maroyi, [14], traditional healers are considered as the first option in treating sick people and are readily available any time their service is needed in most rural communities in Africa.

Over the past decades, many studies have been investigating the role of traditional medicine in supporting the healthcare system of developing countries especially in Africa. However, information on traditional medicine trend and future direction of traditional medicine in Sierra Leone is scarce if not unavailable. This chapter intends to bridge this gap and throw light on the importance and sustainable future of traditional medicine practices in Sierra Leone.

2 Overview of Traditional Medicine and Practice

In Sierra Leone, literature on the medicinal role forests plants in supporting the healthcare system is limited. Traditional healers are known to provide diverse medical care especially in rural or remote communities where they live using plant herbs, animal's parts, incantations, among other methods based on traditional belief and norms [17, 18]. Across Sierra Leone, there are two recognized categories of traditional healers; (1) Traditional healers (herbalist) and (2) Traditional birth attendants. The former is generalist in the treatment of all kinds of sicknesses using traditional herbs collected from forests [19] while the latter use traditional herbs to deliver pregnant women. The Sierra Leone National Traditional Healer Association (SLENATHA) was established in 1992 with a mandates to monitor traditional practitioner's activities in the country. In Africa and Sierra Leone in particular, distinguished scholar's publications have encompassed a wide scope of traditional medicines, herbalist, and sicknesses cure by traditional medicines [20]. Eisah et al. [21] conducted a study on the various uses of medicinal plants by indigenes of forest edge communities in Moyamba District Sierra Leone. Similarly, Johnny et al. [22] carried out a survey to ascertain the various uses of medicinal plants in southern Sierra Leone. Alternately, Jusu and Sanchez, [23] investigated the threats and opportunities associated with medicinal trade in Sierra Leone. The ethnobotanical importance and conservation status of sacred groves associated with the Kpaa Mende in Sierra Leone was investigated by Lebbie AR, Guries RP [24]. The medicinal plants of Pujehun District, Sierra Leone and their uses were recorded by Macfoy CA, Sama AM [25]. Ranasingle et al. [26] investigated the combined use of plants herbs in treating malaria within Bo district of Sierra Leone. Lebbie and Turay, [27] examined plant use as antivenom against snake bites in Southern Sierra Leone. Furthermore, Lebbie et al. [28] assessed the ethnomedicinal knowledge of plant among herbalists in Liberia. In South Africa, Okaiyeto et al. [29] investigated the hostile effects and cytotoxic ability of traditional herbs in Africa. In addition, Hughes et al. [30] studied the relevance of traditional medicine in curing chronic non-communicable diseases in South Africa. Ngarivhume et al. [31] explored the various traditional medicines used by herbalist to cure malaria illnesses in Zimbabwe.

Globally, studies on traditional medicine's well-being and health importance have gained momentum in recent times thereby triggering a global debate on the subject matter among the scientific community [32–34]. These publications have shed great light on the socioeconomic and spiritual importance of traditional medicines to healthcare system. A recent publication of FAO [35], assessed "*forest pathways for green recovery and building inclusive, resilient and sustainable economies.*" Munyaradzi [36] did a critical analysis on the ethical dilemmas surrounding herbal medicine and spirituality. Karrjalainen et al. [37] examines the link between forests and human well-being and identified the challenges affecting this relationship. Mirzaie et al. [38] assesses the possibility of using traditional medicines to treat Covid-19. Noronha et al. [39] reviewed traditional medicines' ability to treat malaria in India and discovered that traditional medicine plays a central role in supporting the healthcare system of India. Similarly, Suswardany et al. [32] critically reviewed the role of traditional medicine in treating malaria ailment in Asia-pacific region. Marqures et al. [34] tried understanding the traditional healing morals and beliefs in ensuring good health and well-being of society. Eshete and Molla [20] studied the cultural importance attached to medicinal plants used to cure sicknesses among the indigenous people of Suro Barguda District Ethiopia. Khatib et al. [40] inspected the various common uses of traditional medicines in Syria.

2.1 Traditional Medicine Plant Richness in Africa

Africa accounts for 25% of the global plant species with an estimate of 45,000 native plant species used as traditional medicine. Off this estimate, about 5000 plant species are used as traditional medicine to treat malarial, pain, cancer, bone fracture, and spiritual encounters [41]. In addition, plants have been reported to possess several pharmacological attributes including antimicrobial [42–51], insecticidal [52–54], analgesic, anti-depressant, anti-malaria, antianxiety, antidiabetes, antimicrobial, antioxidants, anti-helminthes, anti-ulcer, anti-inflammatory, hyperlipidemia, anti-hypercholesterolemic, antiatherogenic, antitrypanosomal, anti-modulatory, antispasmodic, antidiarrheal, and antifertility activities, among others [45]. Across developing countries like Sierra Leone, Liberia, Ghana, Nigeria, etc., traditional medicines are called by different names such as native medicine, herbal medicine, local medicine, ethnomedicine, folk medicine, bush medicine, primitive medicines, alternative medicine, among other names [5]. Traditional medicine is the oldest form of healthcare system that has stood the test of time in low- and middle-income countries.

In Sub Sahara Africa, scientific research has been carried out to authenticate plant extract use for medicinal purposes over the past decades. Literature suggests that, traditional medicine utilization knowledge is being transferred to generation mostly via tribal tradition link [2, 55]. In Sierra Leone, for instance, plant resources have been known to cure different sicknesses and diseases especially in hard to rich communities where Western medicinal services are limited. Drugs such as chemotherapy, artemisinin, and morphine are all derived from African plant species. These drugs and other traditional medicine derived from plants have directly and indirectly contributed to the socioeconomic development of African countries since time immemorial. However, different countries and communities differ in plant resources used as traditional medicine due to their culture and religious beliefs. According to WHO report, about 20,000 plant species have been proven to have medicinal attributes and is used by 80% of the remote global population to cure various sicknesses and diseases. Remote communities in Africa and Sierra Leone in particular relies greatly on traditional medicines for their health problems. Others rely on traditional medicines to solve spiritual encounters and appease their ancestors. Some plants can cure multiple sicknesses or diseases and are used for other purposes as well. For instance, some plants are used for clothing, fodder, food, fuel, medicines, shelter, and medicine [56].

2.2 Plant Part's Use to Prepare Traditional Medicine

In most parts of the world, traditional medicines are extracted from different parts of a plant by herbalist and spiritualists. Some medicinal properties are extracted from the roots while other are extracted from the leaves, stem, fruits, and bark. Similarly, the seeds of some plants serve as medicinal component in most trees. The various techniques used to prepare medicinal properties from plants are: boiling, soaking, heating, chewing, and rubbing [24, 57]. In addition, some traditional medicines are consumed as hot tea on a daily basis. Leaves, roots, and stem parts of medicinal plants are sometimes sun-dried, ground, and mixed with clay soil for external application to cure bone fracture, or reduce swelling of body parts [24]. The grinded plant supplements are mostly molded into lumps and applied on the affected body part. In Sierra Leone, traditional medicines from plant play a significant role in the livelihood activities of remote rural communities [22]. These plant parts used as medicine are processed via various means. Some plant parts such as leaves, fruits, barks, and twigs are boiled to extract the medicinal component from them. Other plant parts like the bark, leaves, and stem are ground and sometimes sun-dried to enhance it healing power. Plant parts that are mostly ground and dried are used externally while those boiled are used for drinking or heating. Some plants produce oil components, which are mostly rubbed to treat skin diseases or swelling. In some cases, two or more plants are mixed to form an infusion decoction that is consumed to cure various sicknesses [24].

Sierra Leone is endowed with abundant natural resources in the form of plants, wild animal's minerals, water, among others [58]. The use of herbal plant medicines in Sierra Leone dates back to the return of free slaves in the eighteenth century. Across Sierra Leone, diverse variety of traditional herbs are used as traditional medicines to cure countless diseases and rare illnesses not treated in conventional healthcare facilities [22, 59]. The absence of alternative Western medicines during those eras forced native Sierra Leonean to explore the medicinal properties of trees found around them. In Sierra Leone plants are the primary traditional medicines that is relatively available and cheap to acquire in any community [22]. The continuous utilization of traditional plant medicine knows no boundary and is practiced in many parts of the world. However, different regions and ethnic groups in different countries use different plant component to cure different illnesses troubling the local population. Although a fraction of the population uses animal component to cure illnesses, however, majority rely on plant supplement to curb various sicknesses especially in remote rural communities in Africa. Plants are not only used by human to cure sicknesses, but are also consumed by animals for health reasons especially in the northern part of Sierra Leone [22, 60].

Animal parts are also used for herbal or medicinal purposes in Sierra Leone [61]. The bones and skin of certain animals are used to cure many sicknesses in Sierra Leone. For example, the bones of Bamboo are believed to possess great power and are used to cure physical weakness in both male and female. While some drink the boiled water of these animals, others tie the bones around their waist or neck for muscular power and spiritual protection. In developing countries with poor infrastructure, these healers are located in nearly every rural village setting as well as in the busy urban areas. While underappreciated, they may play a key role in solving the continent's diverse health problems that governments have not been able to handle since time immemorial. Traditional medicine involving traditional healers and the use of herbs, animal parts, spiritual therapies, manual therapies, and exercises remains common in sub-Saharan Africa, where more than 80% of the people use herbs to treat their illnesses [10].

2.3 Traditional Medicine Dosage and Quantification Controversies in Sierra Leone

Although herbal medicines play a key role in solving the health crisis in Sierra Leone over the past centuries, critics argue that the lack of accuracy in prescription in terms of how much to consume; when to consume, and interval to consume render these medicines inferior to Western medicines [62]. Also, the absence of adequate warning of their side effects or reaction by traditional healers further cast doubt on the safety of these drugs as compared to Western medicines. Some traditional healers across

Africa and Sierra Leone in particular, only instruct patients to rub or drink local herbs given to them but the quantity to drink or amount to rub externally is never specified. The absence of traditional prescription directives has led to the loss of thousands of lives in rural communities especially rural people across Sierra Leone. Local patients who survive over-dosage sometimes go insane. In addition, most traditional medicines from local healers come with strict instruction to maintain the healing power of the herb. Most traditional medicine prepared by herbalist have rules and regulation to follow if the therapy is to act accordingly. For instance, some traditional healers will instruct patients not to lay the herbs on the ground for any reason. Failure to comply by these rules most times render the medicines useless. Also, some traditional medicines are forbidden to be touched by women and exchanged between people. For instance, some traditionally made infusions can't be handed over directly from one client to another, instead, the medicine is placed on the ground for the other client to pick from the ground. Other instructions include applying only in the morning, or at midnight or preventing the opposite sex from touching it during application.

2.4 Traditional Medicine Preparation and Processes in Sierra Leone

The preparation of herbs for medicinal purposes differ with herbalist, regions, and traditional beliefs and religious practices across regions and countries. Certainly, there is no one-size-fits-all approach in preparing or processing traditional medicines. Some medicines are prepared by macerating plant leaves in either cold or hot water to prepare the infusion for drinking [24]. Some plant parts like the leaves and barks are pounded, sieved, and water added to generate the required infusion needed for drinking. In other cases, plant parts are burned to ashes in order to prepare the required remedies. However, in certain tribal or ethnic regions in Sierra Leone, herbal remedies are either boiled, heated, or sun-dried. For instance, medicinal herbs that require pounding in the northern part of Sierra Leone before infusion may not need pounding in the southern part of the country. Similarly, some plants are used to cure different illnesses along different ethnic communities in Sierra Leone. In some cases, two or more plants are collected and mixed together to form a drinkable infusion. The process could either be through pounding, cuttings, boiling, sun-drying, burning, or heating of various herbs. These processes however have strict rules to follow while preparing theses herbs for infusion. The negligence of these rules sometimes render the prepared herbs useless or powerless.

2.5 Traditional Medicine Contribution to the Spiritual and Social Well-Being of Rural Communities in Sierra Leone

In rural communities today, traditional healers are the borne to managing disease and other sicknesses that affect their livelihood and wellbeing. Most of these herbalists use spiritual enchantment to remedy various ailment and the same time drive away evil spirits that are believed to be the cause of these ailments [20, 33, 36, 63]. In Sierra Leone, traditional medicines still remain the most easily affordable and accessible treatment source of various illnesses in the healthcare system of the country. This could be attributed to the inability to access modern healthcare system and where available the cost is beyond the earning capability of most rural people. Traditional medicines serve as a nexus of interaction among herbalist, indigenous people, and the formal healthcare system in Sierra Leone. Traditional herbs collected from nearby forests in Sierra Leone is mostly utilized for the treatment of diverse illnesses suffered by the indigenous people of these communities across Sierra Leone. Besides treating ailments, traditional medicines have a more holistic tactic in enhancing rural livelihood and fulfilling the beliefs and norms of indigenous people in Sierra Leone. For instance, herbalist with their traditional medicines play a key role in societal activities considered as sacred ancestral tradition that also serve as social platforms in local communities in Sierra Leone. In Sierra Leone and beyond, herbalists with their traditional medicines are embedded within the healthcare system and are respected for their spiritual healing of sicknesses that modern healthcare can't detect or diagnose. These traditional medicines provide perfect societal imbalance through physical and spiritual healing of all class of people in society [63–66]. Traditional medicines have provided massive economic, socio-cultural and spiritual benefits for practitioners engage in the act since the independence of most countries in Africa.

However, critics have associated herbalist and traditional medicine with witchcraft, evil spirits, and magic, which are morally considered harmful to the well-being of society [67, 68]. Therefore, must people in urban and rural communities in Africa and Sierra Leone in particular view traditional medicine with negative lenses. Also, the use of traditional herbs to harm or kill people from afar or to manipulate people's destiny [69] are reasons why traditional medicines importance is undervalued and less reported in Africa and Sierra Leone in particular.

3 Orthodox Medicine Sustainability

3.1 Role of Forests in Sustaining Traditional Medicine

Forests are of national and global importance especially in developing countries like Sierra Leone [35]. Literature has proven that there is a direct relationship between forests, human health, and well-being [70]. Forests have been enhancing adequate ecosystem functions and services for mankind since time immemorial [71]. Plants or trees provide ecosystem services especially for poor and sustained communities around the world. In addition, forests serve as a direct or indirect reservoir for plant and their products in Sierra Leone. Forests in Sierra Leone and around the world are known to provide adequate ecosystem services that support human health and well-being [70]. In addition, forests help in regulating contagious disease by providing critical drugs needed to heal these sicknesses. Forests are further considered as "plant safe." Besides the role the forests play in conserving plants or trees, the forests provide spiritual, recreational, aesthetic, and cultural services deemed relevant to society. Medicinal plants collected from the forests play a critical role in enhancing healthy living conditions for societies [72]. Forests serve a crucial function in building resilient, inclusive, and sustainable economies across the globe [35]. Literally, majority of medicinal drugs used to cure various sicknesses today are derived from the forest ecosystems [35]. In Sierra Leone, 90% of the traditional medicines are derived from both primary and secondary forests located close to dwelling communities. The presence of large track of forests (secondary forests) in Sierra Leone is an indication that traditional medicines practices is not under existential threat but will flourish overtime if properly managed.

3.2 Traditional Medicines' Usage Perception Among the Twenty-First Century Generation in Sierra Leone

Across Africa, the indigenous knowledge about traditional medicine is widely believed to be transferred from elders or ancestors with great knowledge and belief in the practice to their younger generation. Despite the reliance of the health sector on traditional medicines to cure communicable, noncommunicable, and spiritual illnesses across Sierra Leone, the usage and knowledge of traditional herbs among the young generation is low and inadequate. According to the World Health Organization [8], 80% of African's population uses traditional medicine to meet their basic healthcare needs but majority of these are from the adult population. Besides, the medicinal values of traditional herbs, civilization has added more values to traditional herbs for cosmetics, perfume, dye, and flavors [72, 73]. The improvement in living conditions especially in urban settings of Sierra Leone has deterred the transfer of traditional medicine knowledge from elders of the current generation to the future generations.

In Sierra Leone, traditional plant medicines' knowledge is lodged with elders in society. For instance, a herbalist lamented the following: *"I inherited the skills and knowledge to be a traditional healer from my grandfather,"* [74]. Moreover, civilization and advancement in healthcare system technology is making traditional medicines use unpopular among the current generation of young Sierra Leonean. The unawareness of the importance of traditional medicine is associated with the inadequate availability of innovative scientific evidence on the beneficial importance of traditional medicines to society over the years [73]. Ahmad et al. [75] and Cámara-Leret et al. [76] cautioned that local knowledge on traditional medicines and its practices is negatively impacted by civilization and modernization. The authors warned that if nothing is done in time, great and valuable knowledge about traditional medicine might be lost and not be transferred to the future generation [77]. Across Sierra Leone, most youths are reluctant to take traditional medicine and have since refused to practice the profession. Their excuse for refusing to take traditional medicines is aligned with hearsay side effects and the physical appearance of prepared infusion. The knowledge about traditional medicine is important for the continuity of the practice as drugs can be extracted from fresh plant components, leaves, roots, barks, flowers, buds, stems, and twigs. However, the refusal of the young generation to practice the profession paint a bleak future for the sustainability of the practice.

3.3 Traditional Medicine Contribution to the Socio-Economic and Health System in Sierra Leone

There are approximately more than 45,000 traditional healers across Sierra Leone [78]. Traditional medicine trade in Sierra Leone is estimated at USD 64,000 annually [79]. Interestingly, 30–40% of traditional medicine trade value or income in Sierra Leone is undocumented due to lack of appropriate data base. *Traditional healers have long held a prominent position in Sierra Leone, particularly in rural areas where the majority of the population live and where access to formal health care services is limited* [74]. These traditional healers support the health care system that is deficient in trained and qualified doctors in Sierra Leone and at the same time contribute to the socioeconomic development of rural communities. Medicinal herbs collected by traditional healers contribute to the social well-being of local indigenes by treating sicknesses like diabetes, dysentery, gonorrhea, bone fracture, impotency, and river blindness. People designated as herbalist or traditional healers generate their income from the profession and are considered as key stakeholders in most communities across Sierra Leone [78]. Traditional medicines have over the years not only contributed to solving general health problems but has also been used to prevent, diagnose, and treat both mental and physical ailment [80]. For many traditional medicine practitioners, healing people is their main source of financial income and livelihood. Most of these traditional healers have large families that depend on them for sustenance and survival. More so, about 45,000 or more traditional healers are self-employed thereby reducing the number of unemployment in Sierra Leone. In Sierra Leone, traditional healers are nicknamed "Bush Doctors" or "JuJu Man" and are known to stay in rural settings. Most of the mental health cases in Sierra Leone are treated by traditional healers based on the belief that the ailment is linked with spiritual interference caused by demons and evil spirit [81]. The quest of traditional healers to ensure well-being and healing in society is sometimes rewarding to them and their families through signs of financial appreciation given by healed patients [81]. The fewer number of Western trained medical practitioners created a gap that traditional healers are filling through the treatment of mental disorder, bone fracture, diagnosis, and prevention of problems that Western trained practitioners can't detect [81, 82]. In rural settings across Sierra Leone, traditional healers play an important role in promoting and sustaining affordable health for all irrespective of socioeconomic status. For majority of Sierra Leonean living in rural communities, traditional herbs are not considered inferior to Western medicines. Instead, they are considered as their first aid healthcare treatment capable of treating and detecting illnesses that Western medicine cannot treat or cure with minimal expense. The support given by traditional healers to the health sector in Sierra Leone cannot be overemphasized.

4 Traditional Medicine Threats Face in Sierra Leone

4.1 Threats Facing Traditional Medicine Conservation in Sierra Leone

The increased use of traditional medicine in Africa and Sierra Leone in particular over the past century has attracted huge global focus by the public, policy makers, health practitioners, and researchers, among other key stakeholders in Africa [62, 83, 84]. Irrespective of the global recognition and healthcare importance of traditional medicine, the healing therapy is not without danger or harm. Traditional medicine has been reported to have adverse effects especially when taken incorrectly. Besides the incorrect administering threats facing traditional medicine's usage in Sierra Leone, decline in forests areas has emerged as a major factor threatening the availability of herbs in the near future. Some of the challenges are deforestation, negative perception, bias against Western drugs, practice secrecy, absence of regulatory body for traditional medicines consumption, wildfire, climate change, shifting cultivation, fuel wood collection and charcoal burning, illegal logging and mining, and urbanization [58, 85–90]. The various threats facing traditional medicine sustainability in Sierra Leone are presented in Table 1.

Also, knowledge of traditional herbs is mainly primitive and experience-based therapy, whereas Western medicines are evidence-based. This poses a threat to traditional medicine's knowledge sharing and expertise for the young and inexperienced generation. To be able to diagnose, treat, and prevent spiritual attacks using traditional medicine, past experience knowledge is a prerequisite for the practitioner. In addition, initiation into the secret society is also a prerequisite to practice traditional healing using herbs from the forests. These prerequisites are of little interest to the current generation hence threatening the continuity of the traditional medicine practice. In Sierra Leone, traditional medicine's practice is mostly done by elders and experienced individuals who live among the people they treat. These illnesses curing ability is mostly received from ancestors either physically or in dreams and passed on from father to son or mother to daughter or any other interested member in society before the elder (herbalist) passed on to another life beyond. Nonetheless, this transition process from elderly ancestors to younger siblings is at stake due to technological advancement in medicinal science, rural to urban migration, increase in literacy rate, and public perception about traditional medicines among the elite of society. These challenges pave the way for local scammers who wish to make fast money from fake traditional medicine practices at the expense of vulnerable society members. Unfortunately, there is no active organization monitoring traditional healer's competencies and therapies administered to the public in Sierra Leone. This latest trend of development in traditional

Table 1 Traditional medicine challenges, sources and remedy

Traditional medicine challenge	Literature sources	Proposed remedy
Deforestation	[58, 87, 91]	Ban deforestation, provide alternative livelihood and enforce environment Act
Negative perception	[58, 62, 85, 92]	Increase awareness about the importance of traditional medicine
Shifting cultivation	[58, 86, 93]	Introduce monoculture practices and encourage swamp farming
Climate change	[58, 94, 95]	Adhere to climate change mitigation and adaptation strategies
Fuelwood collection and charcoal burning	[23, 96, 97]	Establish woodlot plantations and provide alternative energy sources
Improper diagnosis	[98]	Improve on diagnosis precision
Total acceptability	[98]	More awareness should be raised
Conservation	[99]	Training on sustainable traditional medicines harvest
Wildfire	[87, 100]	Institute bylaws on wildfire
Lack of functioning policy and legislation on traditional medicine	[23, 85, 89]	Design and develop policies and legislations on traditional medicines use and regulation
Fake traditional healers	[5, 85]	Provide legal framework and license to be issued to herbalists
Religious beliefs	[5]	Increase awareness raising
Plant extinction threats Technological advancement	[87] [101, 102]	Employ good forest management TM should be transformed from experience to evidence based

medicine practice has the tendency to discourage experience and genuine practitioners in societies (Table 2).

5 The Future of Traditional Medicine in Sierra Leone

Although traditional medicine knowledge transfer is under great threat, its uses and dependence to supplement affordable and cheap healthcare system makes it still the most trusted healing therapy in Sierra Leone. The use of traditional medicine is common among the rural population in Sierra Leone and the trend is expected to continue into to the next generation. Nonetheless, the acceptability of traditional medicine and its inclusion into the mainstream healthcare system in Sierra Leone is still a daunting task especially by the elite in urban areas. Over the next decades, the number of traditional medicine practitioners in Sierra Leone is expected to decrease but its practice will continue in remote and hard to reach communities where modern healthcare system is unreachable. In a resource poor country like Sierra Leone, access to Western or modern healthcare system is marred by challenges such as distance, cost, limited medical practitioners, unequal distribution of health clinic,

Table 2 Tree species and their medicinal significance in Sierra Leone

	Name of tree species	Illness treated	Tree parts use	Preparation	Sources
1	*Anisophyllea laurina*	Eye problem, dysentery	Bark	Grinding/ drying	[21, 103]
2	*Cajanus cajan*	Measles	Leaves	Boiling	[22, 27, 25]
3	*Cassia sieberiana*	Stomach ache, malaria	Leaves and fruits	Edible/ boiling	[22, 25, 28]
4	*Ficus capensis*	Closure of the frontal suture in babies	Leaves	Grinding/ heating	[25]
5	*Moringa oleifera*	Malaria	Leaves, roots, fruit, and stem	Boiling, grinding, drying	[22, 61]
6	*Morinda chrysorhiza*	Malaria	Leaves	Boiling	[61]
7	*Phyllanthua Discoideus*	Bone fraction	Leaves	Grinding	Field study
8	*Terminalia ivorensis*	Malaria, joint and back pain. Yellow fever	Stem, bark	Grinding and boiling	Field data 2022
9	*Parinari excelsa*	Toothache, dysentery, stomach pain	Root, stem, bark	Scrapping bark, grinding	Field Study 2022
10	*Spondias mombin*	Menstrual period pain	Leaves	Boiling/ grinding	Field study 2022
11	*Termarindus indica*	Diarrhea, abdominal pain, and dysentery	Bark, seeds, leaves	Heating, boiling, and grinding	Field study 2022
12	*Mangifera indica*	Head and stomach ache, malaria	Leaves, back, and root	Boiling	Field study 2022
13	*Anacardium occidentale*	Stomach ache, skin rash, and diabetes	Bark, leaves Nut, and fruit	Boiling and drying	
14	*Carapa procera*	Fever, dysentery	Seed	Dry	[79, 104]
15	*Hevea brasiliensis*	Heal wounds and sores	Bark and latex	Grinding	[104]
16	*Upapaca Guinanisis*	Treat male impotence and head ache	Bark, leaves	Boiling and heating	[104]
17	*Kola Nitida (kola nut)*	For easy child delivery, stomach pain, prostate cancer	Leaves, bark, nut,	Boiling and nursing chewing	[22, 24]
18	*Garcinia Kola*	Dysentery, diarrhea, back pain impotency, malaria, headache	Leaves and roots	Drying and heating	[79, 104]

(continued)

Table 2 (continued)

	Name of tree species	Illness treated	Tree parts use	Preparation	Sources
19	*Psidium guajava*	Dysentery, diarrhea, cough, stomach pain, ulcers	Leaves, fruits, and bark	Grinding, chewing, and boiling	[21, 104]
20	*Paullinia pinnata*	Ulcer and pile	Leaves, bark, and seed	Grinding	[21]
21	*Diospyros heudelotti*	Children disease	Leaves	Heating	[25]
22	*Parkia biglobosa*	Ulcer and pain	Leaves and bark	Grinding	[89]
23	*Azadirachta indica*	Dysentery, diarrhea, ulcer, diabetes	Leaves, fruits, and barks	Grinding and boiling	[89]
24	*Ceiba pentandra*	Paralysis, diabetes, leprosy	Bark, roots, and thorns	Boiling and grinding	[22, 89]
25	*Daniellia thurifera*	Skin and parasitic infection, headache, and cough	Roots, leaves, and bark	Grinding, chewing, and heating	[89, 104]
26	*Funtumia africana*	Urinary incontinence, cancer fever	Seeds, leaves, bark, and roots	Heating, boiling, and drying	[24, 89]
27	*Acacia pennata*	Tooth ache	Leaves	Heating	[24]
28	*Anthonotha macrophylla*	Dysentery and snake bites	Leaves	Beating, grinding	[24]
29	*Irvingia gabonensis*	Kidney, asthma, and liver	Leaves, roots, and barks	Grinding and boiling	[103]
30	*Cassia sieberiana*	Pain and headache	Bark and roots	Drying	[79]
31	*Alstonia boonei*	Pain, cancer, and dysentery	Bark and latex drying		[79]

[a]This data was collected in the field by the researcher to complete this aspect of the chapter. Field data 2022

and the absence of required drugs in health centers. These challenge stimulate the dependability of indigenous people on traditional medicine, which is cheap, affordable, closer to patients, and easy to acquire. Indigenous people residing in rural communities across Sierra Leone are knowledgeable and will continue the use of traditional medicine to cure ailment at the expense of Western drugs. The resilience nature of traditional medicine in villages and town is due to the acceptability of the practice among citizens of these communities. If traditional medicine knowledge is to be preserved for the next generation, then stakeholders should lead the participation process to entice community involvement in the practice, especially the younger generation. The possibility that traditional medicine will be incorporated or accepted into the mainstream health system in Sierra Leone is unrealistic over the next decade.

Furthermore, the trend of natural disasters and anthropogenic activities is also posing the greatest threats against biodiversity conservation and preservation in the face of growing population in the near future. The increase in shifting cultivation activities, wildfire outbreak, intensive land use change activities, and other land degradation activities pose a great threat to the existence of some endangered medicinal plants in Sierra Leone. The International Union for Conservation of Nature (IUCN) have listed the following plants among other species as threatened in Sierra Leone [105]. The plant species include: *Terminalia ivorensis, Gilbertodendron splendidum, Pterocarpus erinaceus*, *and Gilbertodendron bilineatus.* Most of these species have significant medicinal values that will be lost if these species go extinct [91, 105].

5.1 Conclusion

Traditional medicine is the combination of knowledge and skill by traditional people based on their beliefs and norms to cure and maintain good health in the local communities in Sierra Leone and other parts of the world. Traditional medicine usage in Africa and Sierra Leone in particular has been in existence since time immemorial. Before colonization and independence in Africa, traditional medicine was considered to be the only remedy to cure illnesses physically and spiritually. While traditional medicine has many positive impacts in maintaining the sound healthcare system in remote communities, the practice is not without harmful effects due to incorrect dosage and poor unhygienic preparation of infusion. In spite of the reliance of the health sector on traditional medicines to cure communicable, non-communicable, and spiritual illnesses across Sierra Leone, the usage and knowledge of traditional herbs among the young generation is low and discouraging. The socioeconomic, spiritual, and cultural importance of traditional medicine resonates well with majority of Sierra Leonean who use traditional medicine for healing and income purposes. This could be attributed to the easy access, low cost, and the presence of the herbalist in these communities. In Sierra Leone, there is no one-size-fits-all approach in preparing or processing traditional herbs. While some plants are prepared by macerating plant leaves in either cold or hot water, others plant parts like the leaves and barks are pounded, sieved, and water added to prepare the infusion for consumption. In some instances, plant parts are burned and the ash is used to cure the illness. Traditional medicines are used to cure sicknesses such as malaria, fever, bone fracture, demons, stomach ache, dysentery, piles, among other sicknesses, in Sierra Leone. The review discovered that there are two recognized categories of traditional healers; they are traditional healers and traditional birth attendant.

It is concluded that Sierra Leone is endowed with abundant natural resources in the form of plants, wild animal's minerals, water, among others, which support traditional medicine practitioners. However, threats like deforestation, shifting cultivation, climate change, wildfire, negative perception, religious beliefs among others, are making the progress and sustainability of the practice difficult especially in the twenty-first century. It is therefore, recommended that more awareness raising be done on the importance of traditional medicine to the health status of rural communities in order to motivate the younger generation to join the practice for sustainability.

5.2 The Way Forward

In order to preserve plants with medicinal attributes, measures should be taken to conserve threatened plants. In addition, awareness raising on the importance of medicinal plants should be intensified. The use of traditional medicine to cure rare illnesses should be encouraged by motivating the younger generation through incentives and moral support. Traditional medicine usage is mostly associated with traditional norms and beliefs, therefore, its application and usage should be encouraged to preserve the culture and norms in society.

To prevent fake herbalist from endangering the life of poor rural people, traditional healer's associations and related organizations should review and enact relevant policies that will ensure the sustainability of the herbal medicines in Sierra Leone. Moreover, traditional healers must be given license to practice their professional after going through rigorous assessment by experience herbalist. Any practitioner practicing the profession should be an experienced, competent, resourceful, passionate, and trusted spiritualist or herbalist with a moral attitude. Also, extractions, infusions, decoctions, and other forms of herbal medicine preparation should be done with extra care to reduce side effects or spoilage. Prepared infusions should be tested to detect any harmful reaction that could be envisaged after using the healing substance. Therefore, sound awareness raising should be started to inform the general public about the negative side effects of traditional medicines. In addition, detailed ethnobotanical surveys should be done in Sierra Leone to ascertain the wider functional role of plants in society in relation to the societal beliefs, norms, and traditions of the people. Information gathered should be published to spread plant knowledge to the young generation to show the interaction among plant, environment, and people. Traditional medicine practitioners should be cautious when administering diagnosis to avoid giving misleading infusions to patient. Traditional medicine preparation should follow standard herbal procedures to maintain hygiene of the prepared infusion or decoction. Herbal products like leaves, roots, fruits, barks, among others, should be prepared in hygienic ways to minimize side effects, and dosage must be prescribed correctly.

Herbal Medicine: A Case Study of Kherias, Lodhas, and Mundas Tribes in Southwest Bengal of India

40

Sudipta Kumar Maiti and Anumita Mallick

Contents

Abstract

Ethnobotany is a well-established branch of science today. It includes in its totality the idea and concept of people about plants as living organisms including beliefs and actions about survival, attitudes of people toward the destruction of vegetation, its careful conservation through faith (taboos, totems, clan, etc.), or practical understanding of plants and their continued improvement by selection or manipulation. Ethnobotany has great relevance in a region whose flora is associated with various

uses. The present ethnobotanical study deals with tribes *like* Kheria (Sabar), Lodha, and Munda of southwest Bengal. These tribes are somewhat primitive to this region and have lived for a long period in the natural settings of the region. During this period, a total of 249 plant species have been collected from the study area of lateritic West Bengal. These plants belong to 84 families and 205 genera of the plant kingdom. According to the uses made by Kherias, Lodhas, and Mundas, the plants can be classified as foods and drinks, fodder, medicine (human), veterinary medicine, value-added items, magical beliefs, cultural practices, etc. Besides this, periments have been done to ascertain the phytochemicals present in the claimed five medicinal plants like *Curculigo orchioides* (Amaryllidaceae), *Asparagus racemosus* (Liliaceae), *Smilax ovalifoila* (Liliaceae), *Elephantopus scaber* (Asteraceae), and *Hemidesmus indicus* (Asclepiadaceae). To make it imperative to society, the traditional tribal system of medicine and wisdom must be documented not only because it has always helped to make a breakthrough in the treatment of virulent diseases but also to acknowledge the tribal heritage of using plant resources.

Keywords

Ethnobotany · Tribes · Lateritic West Bengal · Kheria · Lodha · Munda

1 Introduction

Ethnobotany is the scientific exploration of how diverse societies and cultures utilize plants. It involves investigating the intricate relationship between people and plants, delving into their historical utilization in areas such as sustenance, medicine, attire, habitation, tools, and religious or cultural ceremonies. Ethnobotanists are intrigued by the acquisition of plant-related knowledge and practices across different cultures and how these practices have evolved. Ethnobotany is primarily concerned with the documentation and preservation of the traditional knowledge held by local or indigenous communities regarding the management, utilization, and cultivation of plants. Ethnobotanists often delve into the use of plants for medicinal purposes, exploring the active compounds within plants and their applications in treating various illnesses. Many plants hold significant roles in the cultural and spiritual practices of various societies. Ethnobotanists study how plants are integrated into rituals, ceremonies, and belief systems. Ethnobotany investigates the use of plants as food sources, encompassing traditional farming methods and culinary practices. Ethnobotanists also contribute to the conservation of plant resources and the promotion of sustainable practices, recognizing that the knowledge of indigenous communities can be valuable for natural resource management.

By bridging the gap between traditional ecological wisdom and contemporary scientific research, ethnobotany plays a pivotal role in safeguarding cultural diversity, biodiversity, and the sustainable utilization of plant resources. Its significance extends beyond academic realms to practical applications in fields like pharmacology, agriculture, and conservation. Moreover, it offers profound insights into the intricate dynamics of human-environment interactions.

Ethnobotany is a multidisciplinary science, involving in its domain, Anthropology, Sociology, Archeology, Geography, Pharmacognosy, Medical, Economic Botany, and several other allied branches of Botany. On December 4, 1896, Harshberger first applied the term "ethnobotany" to the study of plants used by primitive and aboriginal people. Most of the authors [6–8, 16, 32, 34, 36, 37, 75–79] have interpreted ethnobotany as the total relationship between primitive people and their plant surroundings in the widest sense. But Feulks [17] and Richard [72], Martin [47], Osawaru and Ogwu [63], Ogwu et al. (2016, [56, 58]) have included the entire realm of economic botany, which even includes the modern uses of plants. Ethnobotany deals with not only the useful relationship between plants and men (the man of past and present) but also with the impact of man on his environment and vegetation. The subject ethnobotany includes in its totality the idea and concept of people about plants as living organisms including beliefs and actions about survival, attitudes of people toward the destruction of vegetation, its careful conservation through faith (taboos, totems, clan, etc.), or practical understanding of plants and their continued improvement by selection or manipulation [20, 52–54]. Ethnobotany has great relevance in a region whose flora is associated with various uses such as foods, fodder, medicines (human and veterinary), fuel house building materials, oilseeds, narcotics, beverages, dye, mordant masticatories, gums, resins, agricultural implements, field implements, material culture, magico-religious belief, religious rites, beliefs and rituals from time immemorial. In India, considerable literature exists on medicinal and economic plants (such as Watt 1989–96; [12–15, 35, 42, 45]). Ethnobotany is the discipline that explores how diverse cultures and societies engage with and harness the potential of plants. This field delves into the intricate interplay between humans and plants, encompassing the traditions, rituals, and day-to-day applications of various plant species among indigenous and local communities. Ethnobotanists delve into the multifaceted roles of plants in specific cultural settings, investigating their contributions to sustenance, medicine, shelter, ceremonial practices, and other facets of daily life. By scrutinizing the cultural, ecological, economic, and medicinal significance of plants, ethnobotanists help safeguard biodiversity through the preservation and documentation of traditional plant knowledge.

This chapter aims to provide data on plant wealth of primitive areas and regions where plant and plant parts are widely used for various purposes of human beings, livestock, and others and can add knowledge toward the attitude of the inhabitants to the vegetation of a region and its impact on the environment. The study area for this case study is the lateritic tract of West Bengal covering the parts of civil districts of Bardhaman, Birbhum, Bankura, Paschim Medinipur, Purulia, and Jhargram between latitudes 21° 75′ and 24° 33′ N.

2 Integrative Healthcare: Bridging the Gap between Herbal and Modern Medicine

In the contemporary world, there is a growing trend toward integrative healthcare, where individuals combine elements of both herbal and modern medicine to leverage the benefits of each approach. It is crucial to seek guidance from healthcare professionals to make well-informed decisions regarding the most appropriate treatment options based on individual health needs and circumstances [48–50]. The approach to disease treatment can vary significantly, depending on the nature and severity of the illness and individual factors. Various standard disease treatment methods are outlined in Table 1. The choice of treatment is contingent upon the disease type and stage and the patient's overall health. Consulting medical experts is essential to determine the most suitable treatment plan, with the potential need for a combination of therapies to address different facets of the disease.

Herbal medicine and modern medicine represent two distinct healthcare approaches, each possessing its advantages and limitations. A comparison of these two treatment methods in the contemporary world is summarized in Table 2. Herbal medicine, also known as phytotherapy or botanical medicine, is an approach to healing that harnesses the therapeutic properties of plants and plant-derived compounds for the prevention, treatment, or alleviation of various medical conditions [1, 2, 31, 60, 61].

Table 1 Standard methods of disease treatment

Treatment methods	Standard methods of disease treatment
Pharmaceutical medications	Prescribed or over-the-counter drugs manage diseases by addressing their symptoms or underlying causes.
Surgery	Surgical procedures remove tumors, repair organ damage, or correct structural abnormalities.
Physical therapy	Physical therapy helps treat musculoskeletal disorders that affect physical function and mobility.
Radiation therapy	Targeted radiation therapy is used to eliminate cancer cells in diseases like cancer.
Chemotherapy	Medications are utilized to combat cancer cells, either eradicating them or slowing their growth, often in combination with surgery or radiation.
Diet and lifestyle modifications	Healthy dietary and lifestyle changes, including exercise and stress management, can manage or reverse conditions like heart disease or type 2 diabetes.
Immunotherapy	The immune system is harnessed to fight diseases, especially cancer and other life-threatening infectious and non-infectious diseases, using methods such as monoclonal antibodies and vaccines.
Gene therapy	Experimental gene therapy aims to replace or repair faulty genes in the treatment of certain hereditary diseases.
Alternative and complementary	Some individuals integrate traditional medical treatments with alternative therapies like acupuncture, herbal remedies, or meditation.
Preventive measures	Disease prevention involves a healthy lifestyle, regular check-ups, and vaccinations to reduce the risk of contracting diseases.
Mental health treatment	Psychotherapy and medications are used to manage symptoms and improve well-being, especially in cases of conditions like depression and anxiety.
Rehabilitation	To regain physical strength and function after injuries or surgeries, rehabilitation is essential.
Hospice and palliative care	In advanced or terminal illnesses, palliative care focuses on symptom relief and enhancing the quality of life. Hospice care provides support during the final stages.

Table 2 Comparison of modern and herbal medicine

Aspect	Herbal Medicine	Modern Medicine
Source of treatment	Derived from natural plants, herbs, and botanicals.	Typically synthesized chemicals or biotechnological products.
Historical roots	Rooted in centuries-old traditions and indigenous knowledge.	Evolved through rigorous scientific research and clinical trials.
Regulatory oversight	Often less regulated, leading to variability in product quality.	Heavily regulated by government agencies, ensuring safety and efficacy.
Treatment approach	Holistic, addressing underlying causes and focusing on prevention.	Often symptom-specific, aiming to target and treat specific medical conditions.
Scientific evidence	With limited scientific validation, some herbs have established benefits.	Evidence-based, backed by extensive research, clinical trials, and approval by appropriate agencies.
Consistency in dosage	Dosage may vary based on plant source and preparation methods.	Precise and standardized dosages in pharmaceuticals.
Side effects	Generally considered safer with fewer side effects, but potential for interactions and adverse reactions.	Well-documented side effects and drug interactions, but risk of more severe adverse effects.
Speed of action	May take longer to show results, focusing on gradual and long-term effects.	Typically faster acting, especially in emergencies.
Chronic conditions	Often used for chronic conditions and overall wellness support.	The primary choice for acute and complex medical conditions.
Integration with modern medicine	Used in complementary and alternative medicine alongside modern treatments.	Mainstream medical approach for diagnosis and treatment in many cases.

This traditional healing system has deep roots in various cultures across the globe, persisting as a popular practice in the modern era. The various aspects of herbal medicine are summarized in Table 3. Herbal medicine continues to evolve and integrate with contemporary medical systems, playing a significant role in healthcare worldwide, whether as a complementary or primary mode of treatment.

Plants' therapeutic potential is attributed to their phytochemicals [28–30]. Phytochemistry, the study of plant-based compounds and their chemical composition, is a cornerstone of herbal medicine. Phytochemistry serves as a fundamental element in herbal medicine by elucidating the chemical composition of medicinal plants, enabling the recognition and isolation of active compounds, ensuring product quality and safety, and enhancing our comprehension of herbal remedies' mechanisms of action. It effectively bridges the gap between traditional plant-based healing and modern scientific methodologies, facilitating the development of evidence-based herbal medicine. The pivotal role phytochemistry plays in herbal medicine includes compound identification, isolation of active compounds [22, 23–27, 38–41], quality control, safety assessment, mechanism of action understanding, standardization, drug development, herbal combinations, safety and efficacy, and bioprospecting (Table 4).

Table 3 Aspects of herbal medicine

Aspect	Aspects of herbal medicine
Plant-based remedies	Herbal medicine can utilize various plant parts (leaves, roots, bark, flowers, seeds) in medicinal forms like teas, tinctures, capsules, and topicals.
Traditional knowledge	The knowledge of medicinal plant remedies is passed down through generations, relying on oral traditions and written records.
Holistic approach	Herbal medicine adopts a holistic approach to healthcare, addressing underlying causes of illnesses, not just symptoms.
Cultural and regional diversity	Herbal medicine practices vary across cultures and regions, creating diverse plant-based therapies over time.
Natural healing	Herbal medicines are favored for their natural origins, believed to have fewer side effects than synthetic drugs.
Scientific validation	Recent scientific efforts evaluate herbal treatments, identifying active compounds and establishing evidence-based practices.
Regulatory variation	Regulations governing herbal medicine differ among countries, ranging from stringent to permissive.
Common uses	Herbal medicine is employed for various health concerns, from common ailments to chronic illnesses and wellness support.
Potential risks	Concerns include contamination, mislabeling, adverse interactions, and side effects.
Consultation with professionals	Healthcare or herbalist consultation is advised, particularly for individuals with medical conditions or on other medications.

3 Method

3.1 Source of Information

Various investigators (namely, [3, 9–11, 18, 32–34, 68, 81–83, 84]) have suggested various tools for ethnobotanical research.

Method recognized as adequate for this purpose may be divided into three broad categories:

(a) Ethnobotany of the present: through extensive field studies, carried out among the tribal people. The studies are most effective and informative because the information is recorded on the spot.
(b) Ethnobotany of the past: the glimpses that can be obtained in several ways such as the study of Herbarium and Museum materials, Old literature and archeological remains, etc.
(c) Calculation of use value of the species studied: The use value [70] of each species is calculated by the total number of uses as recorded by interrogating the medicine men and the total number of medicine men interrogated according to the formula given below.

Table 4 Roles and aspects of phytochemistry in herbal medicine

Information	Aspects of phytochemistry in herbal medicine
Compound identification	Phytochemistry identifies and characterizes chemical compounds in medicinal plants, such as alkaloids, flavonoids, saponins, and terpenoids. An understanding of plant chemistry could reveal its potential therapeutic properties.
Isolation of active compounds	Phytochemistry aids in isolating active constituents responsible for a plant's healing properties. These compounds are used in standardized herbal remedies for consistent efficacy.
Quality control	Phytochemical analysis ensures the quality and uniformity of herbal products, helping manufacturers meet regulatory and safety standards by confirming specific constituent presence and concentration.
Safety assessment	Phytochemistry evaluates the safety of herbal remedies by identifying potentially toxic components guiding the establishment of safe dosage guidelines.
Mechanism of action understanding	Knowledge of plant chemical composition deepens the understanding of how herbal medicines work on a molecular level, aiding in identifying specific biological pathways and action mechanisms.
Standardization	Phytochemistry contributes to standardizing herbal products by quantifying active compound concentrations, ensuring consistent therapeutic benefits across various remedies.
Drug development	Research in phytochemistry can lead to developing pharmaceutical drugs derived from plant compounds, with many modern pharmaceuticals having plant origins.
Herbal combinations	Understanding the chemical composition of different plants facilitates the creation of herbal combinations that enhance therapeutic effects or minimize adverse effects.
Safety and efficacy	Phytochemistry supports an evidence-based understanding of the safety and efficacy of herbal medicines, vital for recognition within the medical community and by regulatory agencies.
Bioprospecting	Phytochemical research can lead to the discovery of new chemicals with potential therapeutic applications, contributing to ongoing bioprospecting efforts for natural remedies.

Use value of a species **(UVis) = $\sum$Uis / nis**

Where UVis = Use value of a species
Uis = Total number of uses of the species
nis = Total number of medicine men interrogated

3.2 Fieldwork

The present study is the outcome of careful and planned fieldwork in several selected tribals, particularly Kherias, Lodhas, and Mundas during the last 4–5 years. The areas taken up for study were those where the concentration of these ethnic groups was believed to be intense and the habitats were to some extent isolated from urban populations so far as communication and culture were concerned.

3.3 Informants

As in many other societies, the Mukhya is the hereditary head among the tribals. They are considered good informants in the tribal community. *Vidya*, the medicine men of said tribal communities, are also the informants. These persons are generally the most respected and rather indispensable members of the society. In some places, it is found that old women are the practitioners mainly of female diseases.

3.4 Method of Procuring Information

The procedure of gathering data, in general, was the same as mentioned by [32–34]. It included either interviews of the informants or witnesses of the uses during the period of work in the field.

3.5 Method of Recording Information

A pertinent question may be asked as to what reliance can be put on the authenticity of the statement of the informants. Efforts were made especially in this direction and the same plant materials were made the subject of discussion with various informants on different days and at different habitats.

3.6 Evaluation of Data

Data obtained from different sources as mentioned above have been categorically scrutinized and compared with earlier important publications. In this case medicinal plants – "Glossary of Indian Medicinal Plants" and its supplement [13, 14]; "Wealth of India: Raw Material" ([4]); and "Medicinal Plants" [35] have been taken as standard references.

4 Results and Discussion

4.1 Plant Distribution

During the field studies, a total of 249 plant species were collected from the study area of lateritic West Bengal (Southwest Bengal), which are used by the tribals such as Kherias, Lodhas, and Mundas. Out of 249 plant species, 25 are Monocots, 222 are Dicots, and 2 are Pteridophytes (Fig. 1).

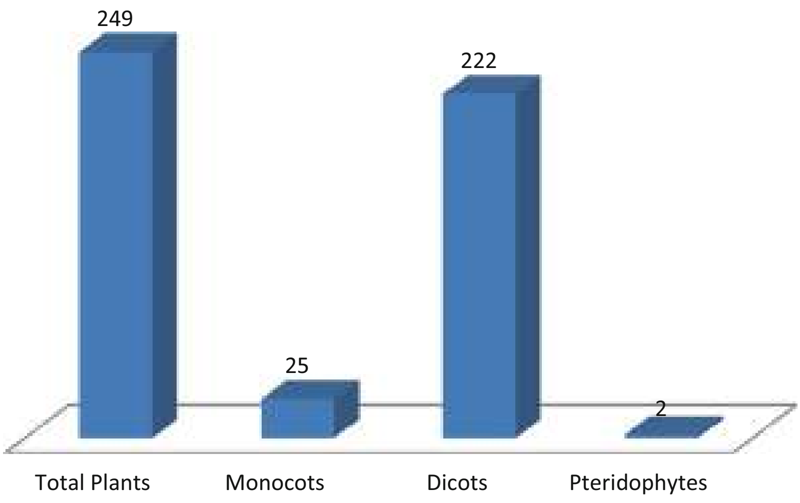

Fig. 1 Distribution of plant species collected during the study

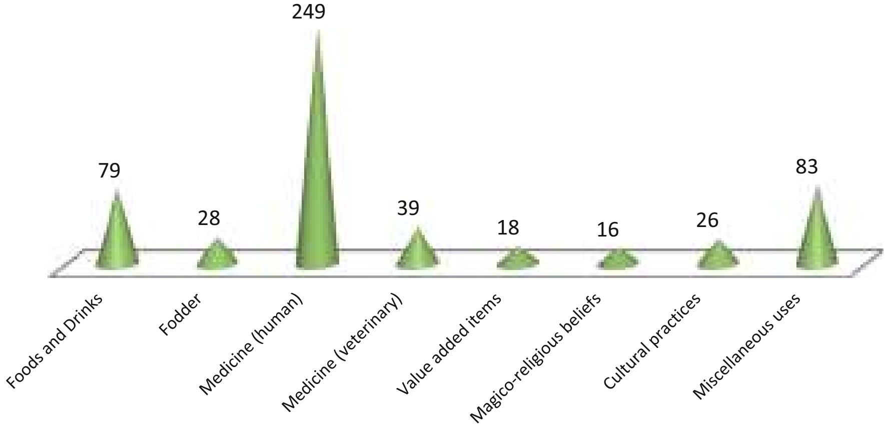

Fig. 2 Distribution of plant species, according to usages by different tribal communities

These plants belong to 84 families and 205 genera. According to the usages made by Kherias, Lodhas, and Mundas, the plant species have been classified as follows (Fig. 2):

1. Foods and Drinks: 79 species.
2. Fodder: 28 species.
3. Medicine (human): 249 species.
4. Medicine (veterinary): 39 species.
5. Value-added items: 18 species.
6. Magico-religious beliefs: 16 species.

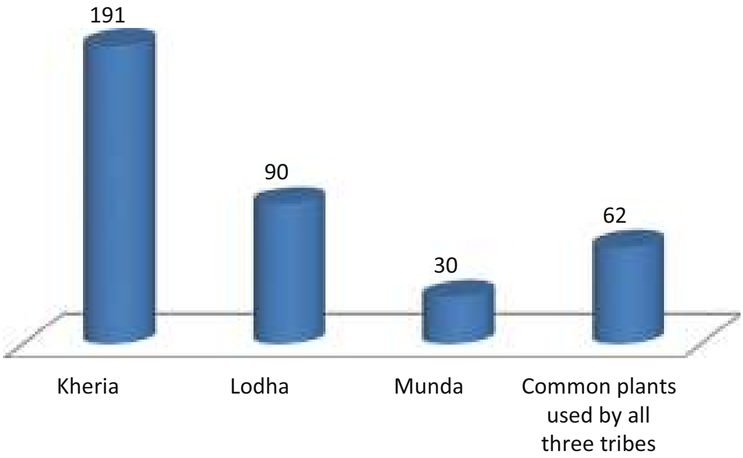

Fig. 3 Number of plant species are used by different tribal communities of the study area

7. Cultural practices: 26 species.
8. Miscellaneous uses: 83 species.

The number of plant species being used by different ethnic groups is recorded below (Fig. 3):

Kheria: 191.
Lodha: 90.
Munda: 30.

Common plants used by all three tribes: 62.

From the analysis, it has been observed that the Kheria is much more knowledgeable about the plant wealth of their surroundings followed by Lodha and Munda. It is interesting to mention that there are plants, e.g. *Abrus precatorius, Abutilon indicum, Haldinia cordifolia, Alstonia scholaris, Asparagus racemosus, Combretum roxburghii, Gymnema sylvestris, Holarrhena pubescence, Semicarpus anacardium,* etc. are commonly used by all the tribal groups. So it can be easily assumed that there is the cross-cultural relationship between the tribal groups of a particular geographical region.

4.2 Ethnobotanical Aspects

4.2.1 Food and Drinks

Though rice is the staple food for all the ethnic communities of this region, a large number of other grains like '*Marua*' (*Elusinecora coma*), *Penisetrum typhoides, Paspalum scrobiculatum, Paspalum orbiculare, Panicum maximum, Echinoclow* *acrusponis,* 'Wild rice' (*Oryza ruphipogon*), *Zea mays, Chinopodium albm,* etc. and wild plants *Dioscorea* plant species*, Asparagus racemosus, Madhuca indica, Diospyrus montana,* etc. are used as supplementary food. In general, the gathering of food plants, their processing, and preparation for consumption are the major routine work of women and children. Male members sometimes collect the fuel wood and help in harvesting the crop if necessary. A total number of 75 plant species are used as food and only 4 plant species are used to prepare drinks and beverages.

It is also observed that plants belonging to the families Poaceae, Fabaceae, Amaranthaceae, Asteraceae, Euphorbiaceae, Araceae, Lilliaceae, Basellaceae, Bracicaceae, Cucurbitaceae, Fabaceae, Musaceae, and Zingiberaceae are in major usage as staple or supplementary food by them.

4.2.2 Fodder

Out of 28 plant species being used as fodder, about 9 species, namely, *Haldiniab cordifolia, Bauhinia purpurea, Canavalia gladiata, Chenopodium album, Chloris virgata, Gardenia gummifera*, *Terminalia perviflora,* and *Rivea hypocretariformis* are less known or unknown as fodder plants.

4.2.3 Medicine (Human)

All the 249 plant species described in one way or the other are used as medicinal plants of which plant parts like roots – 94, stems – 13, barks – 27, leaves – 81, fruits – 17, latex – 18, seeds – 21, bulbs – 8, and tubers (Table 5) are mostly important parts to be used. Whole plants are used in 29 cases only. Besides these, plant parts like flowers, apical buds, spines, etc. are also in use.

The prevailing diseases of the tribals in this region are diarrhea, dysentery, dyspepsia, hepatic diseases, malarial fever, pneumonia, skin diseases like eczema, scabies, ulcer, venereal diseases, conjunctivitis, colic pain, and others [43, 59, 62]. Some of these diseases such as hepatic and skin diseases, etc. are possibly due to consumption of country liquor namely, rice-beer, *mahua* liquor which are consumed without proper hygienic care. Besides these, some diseases are reported as specific to men or women or children in the tribal communities. Men occasionally suffer from headache, eczema, bronchitis, venereal diseases etc., but constipation and appendicitis are uncommon among them. It is because of consumption of large amount of leafy vegetables, which contain sufficient cellulose fibers, and makes the bowl clear. On the other hand, it may be the cause of colic pain, dysentery, indigestion, etc. Debility of sex is recorded among some persons of the communities though it is not very frequent among Kherias and Lodhas. Common female diseases are anemia, white discharge with mucus, dysmenrrhoea (painful menstruation), hysteria, leucorrhea, etc. The practice of abortion is not uncommon. But mostly tetanus is associated with it and is the cause of mortality of carrying mothers. Ignorance and unhygienic condition practiced during delivery of babies is the major cause of this disease.

Similarly some new and important reports on use of a combination of several plants or their parts are also given here. The stem barks of five plants, namely, *Mangifera indica*, *Shorea robusta*, *Spondias cytherea*, *Madhuca indica*, and

Table 5 List of plant parts used by *Kherias, Lodhas,* and *Mundas* of this region

Terminalia arjuna are found to be used in dysentery and diarrhea. Similarly a combination of 4 plants is used against any type of stomach pain, 3 plants as an antidote of snake venom, 4 plants against piles, 5 plants against sexual problems, 5 plants against hepatic troubles, 3 plants against hair falling, 2 plants as anti-pregnancy drug, 3 plants against malaria fever, 3 plants against anemia, 3 plants against tuberculosis, 3 plants against baldness, 3 plants against paralysis, 2 plants against rickets, 5 plants against high blood pressure (Table 6).

4.2.4 Medicine (Veterinary)

The present study reveals that 39 plant species are used as veterinary medicine. The major diseases covered are dysentery, diarrhea, intestinal worm, sores, broken horns, bone fracture, dislocation of bones, dyspepsia, fever, delivery problems, milking problem, foot and mouth disease, swelling of throat, etc. Kheria tribe uses the leaf decoction of *Blumea lacera* orally for dentition. The fruit powder of *Cassia fistula* is orally given to cows during pregnancy for good milk production after the delivery. *Amaranthus spinosus* is used widely for milching cows to increase milk flow. To cure sores *Abuitilon indicum* seed paste is used externally with coconut oil. To get rid of ticks of pets the leaf extract of *Anthocephalus chinensis* is mixed with camphor and smeared on the skin. The fume created by burning of green leaves of *Azadirachta indica* is used as mosquito repellant in the cowsheds.

It is observed that the usages of plants like *Abuitilon indicum, Anthocephalus chinensis, Blumea lacera, Caloptropis procera, Combretum roxburghii, Tamarindus indicus,* and *Vitex negundo* are practically unknown in the veterinary world.

4.2.5 Value-Added Items

The technology used by the tribals in their livelihood depends on the plant wealth. They use a good number of plants for building and shelter purposes, making different implements (hunting, fishing, agricultural, etc.), preparing poisons (used for prey of birds, animals, and fishes), making various material cultural items like utensils, oil extracting equipment, musical instruments (drums, *Kendra*-a string instrument), etc., for extraction of tannin, preparation of country liquor, various artifacts, etc. Tribal people use wooden combs made out of the young timber of specific plants like *Alstonia scholars* and *Gmelina arborea.* Washing powder especially as shampoo is prepared from the ash made after burning leaf of *Acacia auriculiformis.* A mucilaginous shampoo like preparation is made from the flower of *Hibiscus rosa-sinensis.* The colorful seeds of *Abrus precatorious* are used to make ornaments like necklace, earring, etc. The hard shell of the fruit of *Feronia limonia* is used to make different decorative materials. Broom made out of grasses like *Aristida adscenscionis, Vetiveria zizanoides, Thysolena maxima, Sida acuta, Impereta cylindrical* are widely used. They are also marked items in this region. *Sal (Shorea robusta*) leaves are used for making leaf plates and cups. It is also a marketable item. The leaves are stitched with the stem of *Aristida adscenscionis* and leaf petiole of *Azadirachta indica.* The spines of *Barleria prionitis, Acacia nilotica* and thorn of *Aegle mermelos* are used for designing tattoo marks on the body.

68	Unwanted pregnancy	4
69	Urine Clarence	1
70	Vomiting	1
71	Weak heart	2

4.2.6 Magico-Religious Belief

The distinction between religious faith on certain plants and belief in magical power of certain plants is not always sharply demarcated. So here these beliefs are classed under magico-religious beliefs.

1. Annulet: The plants associated with it are mostly for preventing and guarding evil spirits and incurable diseases.
2. Plants for magical cures are associated with curing ailments through charms and others. Such as Lodhas believe that the touch of green leaves of *Azadirachta indica* cures pox.
3. Plant like *Alangium salvifolium* used by Kheria for curing of all sorts of ailments. They believe that the plant is an abode of ghost.

4.2.7 Cultural Practice

Good numbers of plants are associated with the tribal cultures of the study area. They are artificially categorized as follows:

(i) Worship – plants associated with worship and offerings to God, Goddess, and evil spirits.
(ii) Community worship – plants associated with social customs and community worship.
(iii) Religious beliefs and practices – plants considered as sacred plants or associated with religious taboos, totems, myth, legends, etc. The plants are conserved and protected [21].
(iv) Tattooing and body ornamentation – plants used for making tattoo marks on body for body ornamentation for detecting the clan, etc.

It is interesting to mention that the plants used for tattooing purpose are mostly dye-containing plants and practically unknown or less known to the outsiders.

4.2.8 Miscellaneous Use

Plants associated with miscellaneous uses in the lives of the tribal people can be classified into the following:

(i) Masticatories.
(ii) Hallucination.
(iii) Tooth brush.
(iv) Insect repellent, etc.

4.3 Use Value

The use values of different plants dealt here with range from 1 to 6. Out of 249 species, 135 species have their use value between 1 and 2, 32 species have use values within 2.1-3.0, 64 plants have use values within 3.1-4.0, 7 species have use values within 4.1-5.0, and only 11 species have use values within 4.1-6.0 (Fig. 4).

4.4 Phytochemical Study of Some Selected Samples

Phytochemical screening for active constituents present in the alcoholic extracts of the following plants was carried out using chromatography and spectral techniques.

1. *Curculigo orchioides.*
2. *Asparagus racemosus.*
3. *Smilax macrophylla.*
4. *Elephantopus scaber.*
5. *Hemidesmus indicus.*

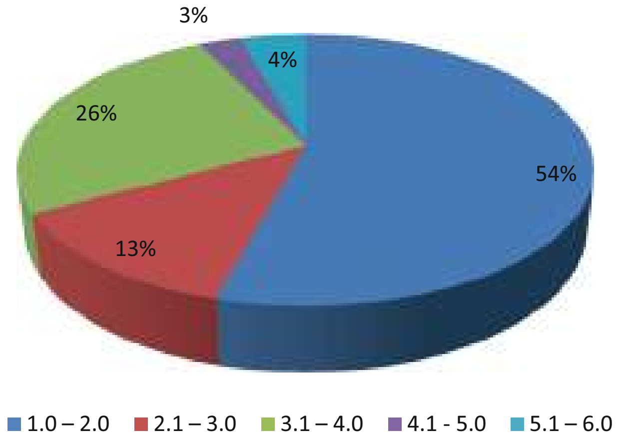

Fig. 4 Percentage of species with different use values

All these samples were tested for specific active constituents and then subjected to thin layer chromatography (TLC) along with UV spcctrophotometry, which are described below:

4.4.1 Phytochemical Screening for Active Constituents

All the samples were chemically tested to ascertain the presence of active constituents, namely, alkaloids, flavonoids, steroids, terpenoids, tannins, and saponins in the extracts. The various chemical tests were conducted and the results obtained in respect of alcoholic extracts of above five plants (1–5) are given in Table 7. Chemical tests indicated the clear presence of steroids, triterpenoids, and flavonoids in the alcoholic extracts of five plants.

The migration of different components of the alcoholic extracts of five different plant samples relative to the solvent front on thin layer chromatogram is expressed by the R_f values. The R_f values of the spots of the alcoholic extracts of five different samples are given in Table 8.

R_f = Distance moved by the spot from starting point / Distance of solvent front from starting point [R_f = Retardation force].

From Table 8 it is clear that sample 1 is the mixture of ten different components, sample 2 is the mixture of six components, sample 3 is the mixture of five components, sample 4 is the mixture of seven components, and sample 5 is the mixture of six components.

The plants studied for their phytochemicals are also used in Indian traditional medicinal system of medicine and have been studied earlier. *Curculigo orchioides* is used in Ayurvedic medicine. It has been observed that glycosides are present in the rhizomes. The tribes referred to in this study also use the rhizome part of the plant. Free sugars, mucilage, hemicellulose, and other polysaccharides are found to be present in this study. The plant yields a flavonone glycoside, which is a powerful

Table 7 Phytochemical screening for active constituent in the alcoholic extracts of five plants

Sample	Alkaloid	Steroid	Terpenoid	Flavanoid	Saponin	Tannin

	R_f Values									
Sample	1	2	3	4	5	6	7	8	9	10
Curculigo Orchioides	0.06	0.22	0.30	0.35	0.37	0.65	0.72	0.76	0.80	0.85
Asparagus Racemosus	0.35	0.39	0.51	0.56	0.77	0.85				
Smilax ovalifoila	0.35	0.38	0.42	0.67	0.87					
Elephantopus scaber	0.38	0.41	0.69	0.74	0.79	0.83	0.89			
Hemidesmus indicus	0.29	0.36	0.71	0.78	0.84	0.90				

The digits 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 represent the R_f values

uterine stimulant in guinea pigs, rats, and rabbits notwithstanding the gravid or non-gravid state [80]. *C. orchioides* is used extensively in Ayurvedic formulation for a wide variety of ailments, specially as a general tonic and as an aphrodisiac. In the Philippines, it is used for skin diseases [46]. The rhizome is also used to make edible flour by many tribal people. Curculigoside, a phenolic glycoside, has been characterized in the rhizome [44]. In the present study, Kherias are found to use the rhizome against snakebite and in sexual debility of women. Lodhas use the plant against scorpion stinging. Mundas use the flower as hallucinating agent. Earlier work done (Bharatiya Vidya Bhavan [5]) in *Asparagus racemosus* shows that saponins are present. Gaitonde and Jethmalani [19] have observed antioxytocic and ADH activity in the saponin fractions isolated from the roots of this species. The plant has been used in Ayurveda as a galactogogue (*Stanya*) to increase milk secretion during lactation. It is also used as a general tonic and as an aphrodisiac. The plant's action as a galactogogue has been reported by Patel et al. [69]. In a study by Sabnis et al. [73], it was shown that in the estrogen-primed rats *A. racemosus* could cause both increase in the weight of mammary lobulo-alveolar tissue and the milk yield. It was attributed to the action of release of cortico-steroids or an increase in prolactine. All the three tribes, namely, Kheria, Lodha, and Munda, use the plant as a general tonic and a promoter of growth and good health. Kherias and Mundas use the plant as a sex stimulant for male. Other than the said uses, Kherias and Lodhas use the plant against Gonorrhea. It is also used as food supplement. Mundas use the root against dysentery and also as a food supplement.

Smilax ovalifoila is a widely used plant in Indian traditional systems of medicine. The genus produces a well-known drug known as *Sarsaparilla,* which is also found in the root of ***Hemidesmus indicus*** (Indian *Sarsaparilla*). Root of the species is used in venereal diseases, rheumatism, urinary complaints, and dysentery. Kherias and Lodhas use the root of this plant to avoid unwanted pregnancy, whereas Mundas use its leaf paste to control the abnormal discharge of semen of male.

There is no record of usage of ***Elephantopus scaber*** in traditional medicine of India like *Ayurvedic* system. Photochemicals like Germacranolide dialactones, amino acids, triterpenoides, sterols, and long-chain fatty acids have been reported in this plant in earlier studies. The use of the root of the plant as emollient (making skin soft) and is given in dysuria, diarrhea, dysentery, and swellings or pain in the stomach has been reported in other traditional medicinal system. The root is given to arrest vomiting, powdered with pepper it is used in toothache. Bruised leaves boiled in coconut oil are applied to ulcers and eczemas. Kherias use the root paste of the plant against elephantiasis. Lodhas use its leaf paste in dysentery. Mundas use the leaf paste to prevent warms in children and also in elephantiasis.

Hemidesmus indicus (Indian *Sarsaparilla*) is a very commonly used plant in indigenous medicinal system. Bharatiya Vidya Bhavan [5] studied its phytochemistry in detail. Essential oil and saponins have been isolated from root extract. The aqueous extract of its root induced a slight increase in urine output in rats; in dogs none of the fractions had any diuretic action [74]. Blood pressure was reported raised in dogs by the drug. The antibacterial activity of the root extract and the essential oil [71] has been reported. It is used as a febrifuge, diuretic, antidiarrheal, and to stimulate lactation. Clinical trials have shown a benefit in ringworm infection and for malnutrition. Kherias use the plant as a febrifuge and also as a stimulant of milk secretion in mothers. They also use it against old ulcers, eczema, and other skin diseases. Lodhas use the plant in snakebite and also as a febrifuge. Mundas use the plant in controlling dysentery.

4.5 Attitude Toward Diseases and Their Diagnostics and Treatment

It is said that nature has created some plant in the world for every ailment, all we have to do is to find it. There is a cure for every disease, men has to find it out.

Tribals of the district are followers of animism. It leads to the belief that disease and certain spirits or supernatural powers cause deaths [51]. Sometimes bigot faith of dead spirits who live with living bodies is in existence. These beliefs have had a significant influence on their attitude and psychology about the ailments. They have to take steps to counteract the inimical influences of the hidden powers, to pacify, propitiate, or satisfy some and to fight and punish others like witches. This is the origin of some of the holy or sacred incantations, invocations, recitations, offerings, sacrifice, amulets or talisman, which are regarded as efficacious in the tribal faith.

5 Conclusion

In conclusion, the study has documented plants and plant parts used by Kherias, Lodhas, and Mundas from an ethnobotanical standpoint. This study highlighted gaps between traditional ecological wisdom and contemporary scientific research. The significance of this report extends beyond academic realms to practical applications in fields like pharmacology, agriculture, and conservation by providing insights into the intricate dynamics of human-environment interactions [55, 57, 64–67]. The choice of plant and plant parts used in the treatment of ailments by people *in* Kherias, Lodhas, and Mundas was observed to be contingent upon the disease type and stage and the patient's overall health. However, consulting medical experts remains essential to determining the most suitable treatment plan, with the potential need for a combination of therapies to address different facets of the disease. Most importantly, the pivotal role phytochemistry plays in herbal medicine and societal development includes compound identification, isolation of active compounds, quality control, safety assessment, mechanism of action understanding, standardization, drug development, herbal combinations, safety and efficacy, and bioprospecting were highlighted. Ethnic groups within Kherias, Lodhas, and Mundas believe that their environment plays key roles in the type of plants found around them, and in turn, the plant and plant parts used in addressing their health issues. Both the Mukhya i.e., the hereditary tribal head, and Vidya, the medicine men within these communities, are very knowledgeable about plants and plant parts that should be used for specific ailments. They are also generally respected and rather indispensable members of the society. Most of the plants used by the communities are Dicots and mostly as foods and Drinks, Fodder, Medicine (human and animals), value-added items, magico-religious beliefs, cultural practices, and miscellaneous uses. Rice was the main staple food for all the ethnic communities in addition to other grains like '*Marua*' (*Elusinecora coma*), *Penisetrum typhoides, Paspalum scrobiculatum, Paspalum orbiculare, Panicum maximum, Echinoclow acrusponis,* 'Wild rice' (*Oryza ruphipogon*), *Zea mays, Chinopodium albm,* etc. and wild plants *Dioscorea* plant species*, Asparagus racemosus, Madhuca indica, Diospyrus montana,* etc. are used as supplementary food. In general, the gathering of food plants, their processing, and preparation for consumption are the major routine work of women and children. Male members sometimes collect the fuel wood and help in harvesting the crop if necessary. The plants were from some of the following higher plant families Poaceae, Fabaceae, Amaranthaceae, Asteraceae, Euphorbiaceae, Araceae, Lilliaceae, Basellaceae, Bracicaceae, Cucurbitaceae, Fabaceae, Musaceae, and Zingiberaceae. Finally, all the 249 plant species described in one way or the other are used as medicinal plants of which plants.

Abstract

The acceptance and use of any system of medicine is influenced by belief of their practitioners, founders, teachers, and most importantly the general public. According to the World Health Organization, 80% of herbal medicines are utilized worldwide for better heath. The strong belief systems that underpin herbal medicine are crucial to comprehending the concepts of health, disease, disease physiology, disease pathology, and treatment modalities. One of the oldest medical systems is Unani, which primarily uses plants as a form of treatment. The fundamental knowledge of Unani medicine was collected by famous scholars of ancient time like *Buqrat* (Hippocrates 460 BC, Greece), *Jalinoos* (Galen 129 CE, Anatolia), *Zakariya Razi* (Rhazes 854, Persia), *Ibn Sina* (Avicenna 980, Persia), and later on *Hakim Ajmal Khan* (1868, India) emerging to be a significant contribution to its spread in India. The foundation of the Unani system is based on the core theory of the seven basic physiological principles, temperament, self-regulating power called "*Tabiat*," and six essential factors. Unani scholars employ these theories as therapeutic and diagnostic tools in their clinical practices. Patients and general population's belief on herbal medicine particularly Unani medicine varies. Some common believes are the following: It is restrained to Muslims only, is harmless, can be taken without advice of a physician directly over the counter, is only effective in chronic diseases, and can be taken in addition along with conventional medicine. The physician should be a religious or spiritual preacher, according to the general public's perception of Unani practitioners. These viewpoints are similar to those of other branches of traditional medicine, which all employ holistic approaches to treat illnesses rooted in a close connection to the associated religion. As a result, different groups of people favor these branches of medicine for their medical needs.

1 Introduction

While there is much to be learned from looking at the drawings, records, skeletal remains, and surgical equipment of early humans, it is thought-provoking to extrapolate their sense of death and sickness. History not recorded or written is difficult to understand. It is possible that as they acquired cognitive abilities, they discovered by trial and error which plants could be consumed as food, which were poisonous, and which offered some therapeutic benefits [1]. Folk medicine, also known as domestic medicine or traditional medicine, which is primarily centered on the utilization of plants or herbs, minerals, and animals as sources of health, had its start in this way and is still practiced today. However, early humans did not view illness and death as natural events [2]. There were common illnesses like colds, coughs, and fevers that were treated with the available herbal remedies and were considered to be a normal part of life, but there were serious and incapacitating illnesses that came from a supernatural source, the result of a curse that the victim's enemy had placed on them, a visit from a malicious expert, or the handiwork of a wrathful god who projected an arrow, stone, or worm into the victim's body. The next phase was to attract the wandering spirit back to its rightful abode within the body, where it could then be driven away either by a dart or a demon [3, 4].

In Britain, France, Peru, and other parts of Europe, trepanned skulls from the prehistoric past have been discovered. The fact that many of them exhibit signs of healing shows that those who practiced trepanning, also known as trephining, thought the disease would leave the victim's body by drilling a hole in their head. Although it is rapidly disappearing, certain Indigenous people still practice it in specific areas of Algeria, Melanesia, and possibly elsewhere [5].

Early human society's medical practices were heavily influenced by magic and religion. Blasphemies, dancing, scowling, and all the tricks of the magician were used along with medication or treatment. Magicians were the only doctors that used amulets, broken bones, and ornaments, which is still common today and has ancient roots [6].

Early healers used a holistic approach (mental, physical, and spiritual) to demonstrate their abilities, and because both healer and patient had faith in the efficacy of treatments, even those that had no evident physical impact on the body would have made a patient feel better. This alleged placebo effect is still relevant in modern systems [7].

The emergence of writing and the calendar foreshadowed the beginning of written history. The earliest records of knowledge are only found on clay tablets with cuneiform seals and indicators used by ancient Mesopotamian physicians. The Code of Hammurabi, which was composed in the eighteenth century BCE by a Babylonian king, is kept on a stone pillar in the Louvre Museum in France [8]. A more precise image can be created by looking at Egyptian medicine. The first physician to appear was Imhotep, chief minister to King Djoser in the third millennium BCE. He constructed one of the first pyramids, the Step Pyramid at 'aqqrah, and was thereafter worshipped as the Egyptian deity of medicine and associated with the Greek god Asclepius [9]. A more certain understanding can be gained from studying Egyptian papyri, especially those discovered in the nineteenth century by Ebers and Edwin Smith. The former is a list of cures with the appropriate spells or incantations, while the latter is a surgical treatise on the treatment of wounds and other injuries [10–12].

2 Belief Systems of the Indian Medicine

The ancient Indian system of medicine is regarded as the most systematic and holistic system, both in terms of its theories and its therapeutic approaches, among all the ancient civilizations of the world [13]. There is no shortage of writing on the medical systems and literature of ancient India, according to an examination of Indian medical historiography [14]. However, the individuals in charge of the healing have not gotten much recognition. The Sanskrit word "*Ayushman-bhava*" which means long life is the source of the term "AYUSH" [15]. Since the time of the Mahabharata, this phrase has been used frequently as a blessing for a healthy, long life. Currently, the Commission for Scientific and Technical Terminology has chosen the term "AYUSH" to refer to all "traditional and non-conventional systems of health care and healing, including Ayurveda, Yoga, Unani, Naturopathy, Siddha, Sowa Rigpa, Homoeopathy." The entire medical system covered by AYUSH is based on the time-tested holistic method of treating illness and promoting healing. Even in the contemporary period, AYUSH plays a crucial role in fostering Indigenous healthcare practices and maintaining traditional medical knowledge. It also offers populations better, more accessible, and affordable healthcare.

2.1 Belief System of Unani Medicine

It is fundamentally different to compare holistic Unani medicine to reductionist Western medicine. In order to provide better healthcare, Unani physician should be well-versed in the fundamental principles of Unani medicine, including disease diagnosis, drug selection, and treatment methodology [16].

The two states of the human body according to Unani philosophy are *Sehat* (state of health) and *Marz* (state of disease). A person should have a healthy constitution and morphology in accordance with their needs to be in a state of health, which is a naturally occurring physiological condition. As a result, the body functions normally and the individual has a tranquil and healthy life. Harmony of the seven basic components (*Umoor Tabiya*), *Arkan* (Element), *Mizaj* (Temperament), *Akhlat* (Humors), *Azaa* (Organs), *Arwah* (Pneuma), *Quwa* (Faculties or Powers), and *Afal* (Functions) are responsible for healthy and peaceful life while changes in any one of these elements can lead to illnesses or even death [17]. Both the cause and prevention of disease employ *Ilmul Asbab*. In Unani philosophy, Asbab (causes), *Alamat* (symptoms), and *Ilaj* (treatments) should all be very precise and tailored to the individual. Therefore, a treatment plan that enables the eradication of disease-causing factors and the restoration of health must include an understanding of *Ilmul Asbab*. *Asbab Sitta Zaruriyya*, the six essential factors for a better and healthier lifestyle, are one such preventive strategy that the treating physician should be well-versed in [18].

Classification of *Asbab* (Causative factors) is illustrated in Fig. 1.

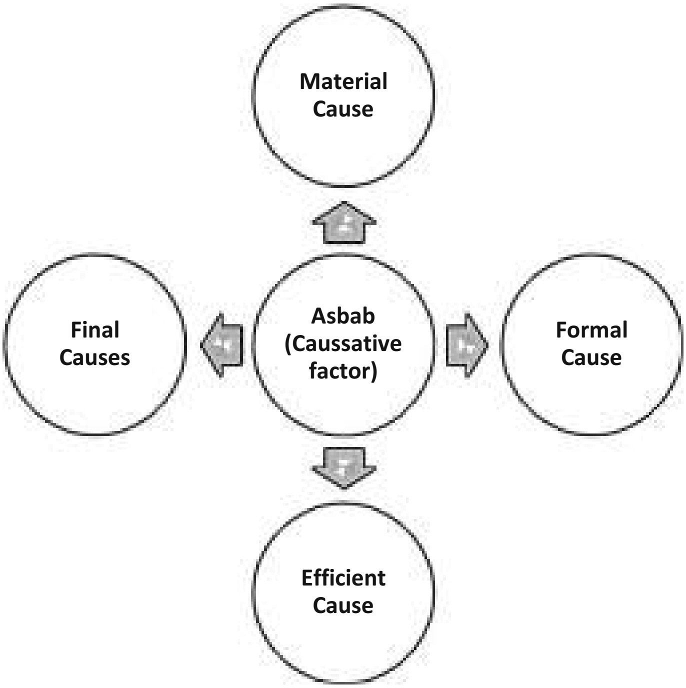

Fig. 1 Classification of *Asbab* (Causative factors)

Above are examples of material causes being *Arkan* (Primordial Essence), *Akhlat* (Humors), *Aza* (Organs), and *Arwaah* (Pneuma), whereas examples of formal causes include *Mizaj* (Temperament), *Quwa* (Faculties), and *Tarkeeb* (Structure). The final cause contains *Afal* (Functions), which are the desired natural result. An organ's dysfunction reveals an organ's disorder. The efficient cause is made up of six essential factors (Air and water, physical and mental movement, physical and mental rest, sleep and wakefulness, body retention, and evacuation), as well as nonessential factors [19].

One of the enduring contributions to the science of medicine is the Hippocratic humoral theory. Based on the current scientific and philosophical views of the time, ancient physicians developed a revolutionary system for deciphering and treating disease as well as maintaining health [20]. The humoral hypothesis of disease was named after this framework. The philosophies of the ancient Greeks were blended into moral theory in order to explain health and sickness as well as provide recommendations for treatment. The foundation of the humoral hypothesis is the firsthand observation of natural phenomena. Hippocrates in particular attentively studied the onset of disease in his patients and drew conclusions from his findings, as did other ancient Greco-Arabic doctors. The origin of disease's material causes was the humoral pathogenesis of illness [21].

2.2 Concept of *Tabiat* (Supreme Power/Immune System) in Unani Medicine

The preservation of one's health and the normal constitution of the human body are the major objectives of Tabiat as per Unani fundamentals [22].

A strong *Tabiat* maintains the physiological function of each organ and supports and generates a healthy body. It also shields the body against unhealthy situations and pathological conditions. Maintaining the integrity of the body requires the association of the seven fundamental components (*Umoor Tabiya*), which have opposing and similar characteristics and make up corporeal creatures. Additionally, due to their oppositional nature, these components have a propensity to separate from corporeal objects. To keep them organized, a force is therefore required, and *Tabiat* is the power that unifies all elements. It is the supreme planner since it creates a healthy environment inside the body and prepares it to fight disease. It is also known as a person's individual hidden power or administrative system known as *Quwate-Mudabbar-e-badan*. When it is strong, a person is not prone to illness of any kind; when it is weak, a person is more likely to become ill [23].

Diseases are thought to be brought on by atmospheric microorganisms, according to the theory of allopathic medicine. The environment in which people live contains a variety of elements and causes that alter the body's natural homeostasis. The health of the body is affected by these elements, but not all of the population is equally affected. This suggests that everyone possesses a secret ability that, depending on the individual, can defend them when it is strong. *"Tabiat-i-Insaniya"* is the name of this secret power. It is the force that unknowingly and involuntary controls and manages the human body. The concept of existence of *Tabiat* can be preserved by interpreting it in accordance with other medical systems within the bounds, as doing so would uphold Unani Tibb's honor and legitimacy [24].

It is compared to immunity by some academics. Although immunity is a part of *Tabiat*, it is not the same as *Tabiat*. Cameron Gruner, who has a firm belief in the idea of *Tabiat*, is the individual who has this belief [25]. According to him, Tabiat is a more complete idea in Unani Tibb than the germ theory or any other theory. He adds that Ibn Sina's embrace of this idea is the main reason he likes him. Loyal Sherald and Dr. Weil Fraid Narth Field were also ardent proponents of the idea or theory of *Tabiat*. According to Dr. Weil Fraid Narth, it makes no difference whether someone agrees with this idea or not. These academics held a firm belief in the idea of Tabiat despite the fact that they were not Unani Tibb scholars [26].

2.3 Epidemic and Pandemic in Unani Medicine

Nearly all of the historical civilizations had an impact on the development of Unani medicine. Hippocrates wrote a treatise about pandemics and epidemics (460–380 BC). Ancient medics regularly used the term "epidemic" in the same way as it is used now, referring to any illness that affects a large number of people in one place at once [27]. The classic Unani literature also touch on the fundamental ideas of epidemics and pandemics, including their causes and preventative strategies. According to the genesis approach, imbalances in the humors or production of abnormal excessive humors within the body and invasions by foreign bodies that target the humors are the two fundamental causes of epidemics [28]. The second group of diseases includes infectious and epidemic conditions. Ancient literature mentions a number of precautions against pandemic and epidemic situations. In his Canon of Medicine, Avicenna described the epidemic diseases as *Amraz-e-Wabai* and advised isolation at home when one was present. *Al - Rhazes* had the concept of quarantine [29].

In addition to isolation and quarantine, three additional measures – (i) environmental purification utilizing specialist herbal pharmaceuticals as fumigants or sprays, (ii) immunomodulation and health promotion, and (iii) usage of preventive and symptom-specific medications – are of utmost importance [30]. According to recent scientific studies, several herbal single and compound formulations that contain antipyretic, anti-infectious, and numerous pharmacologically active substances are indicated in classical Unani scriptures. These formulations may provide new insights into the prevention and management of epidemics and pandemic [31, 32].

2.4 Diagnostic Tools in Unani Medicine

Physical examination and observation are used to make diagnoses in Unani medicine. More focused on the signs and symptoms of illnesses rather than laboratories

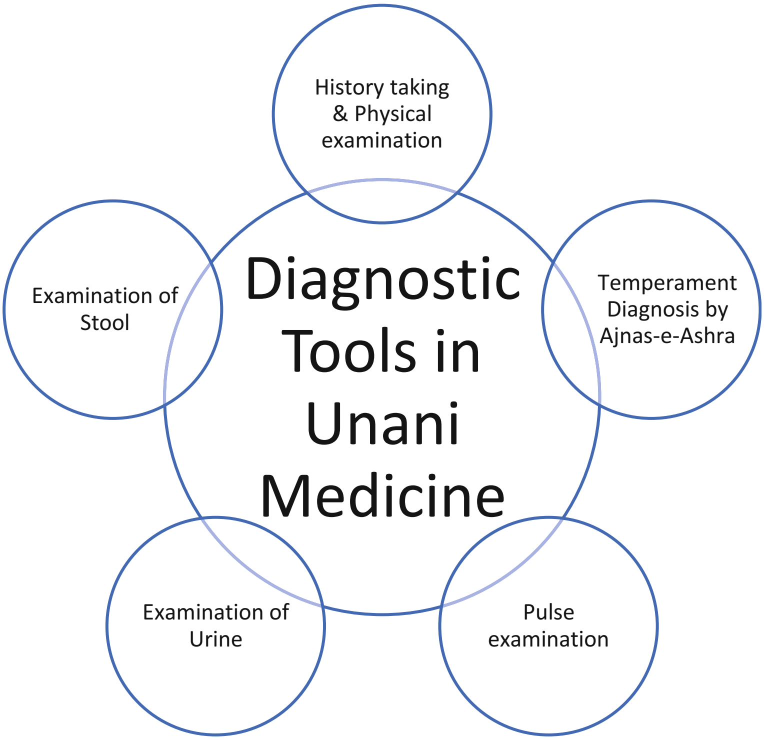

Fig. 2 Diagnostic tools in Unani medicine

values. By taking a detailed history and performing a physical exam, subjective parameters are accessed [33].

In some instances where they are helpful on a secondary level, it also has the intellectual foundation to employ contemporary medical diagnostic techniques. For instance, it does not hesitate to use endoscopy to determine the amount of structural discontinuity because it views it as a fundamental pathology. The history, physical examination including temperament (*Mizaj*), pulse examination (*Nabz*), and inspection of excreta (*Bol w Baraz*) are all included in the unmatched comprehensive diagnosis of Unani medicine. Figure 2 is depicting the diverse diagnostic tools used in Unani medicine to arrive at a comprehensive understanding of the patient's history [34].

2.4.1 The History Taking and Physical Examination

It is carried out in accordance with both general guidelines and the specific guidelines required by the patient's individual situation, primarily under the guidance of the "Ten Fundamental Categories" (*Ajna's Ashara*) of *Mizaj* [35].

2.4.2 Examination of *Nabz* (Pulse)

According to Unani medicine, the human pulse results from the heart and arteries' alternating contraction and expansion, which regulates breathing through inspired air. This idea states that every pulse consists of two motions and two pauses. The ten parameters that comprise the pulse's foundation are size, strength, speed, consistency (elasticity), fullness, temperature, rate, frequency (constancy), regularity, and rhythm. Complex pulses have also been thoroughly documented in Unani medicine. Based on general criteria, specific pulse types linked to each ailment are also identified [36]. Classical Unani writings indicate several conditions to check the pulse for both patient and physician. When checking the patient's pulse, for instance, the thumb should be held upward. At the time of the evaluation, both the patient and doctor should neither be suffering from any emotional or mental disorders, nor be hungry or have a full stomach. It is critical to compare the patient's pulse to that of a healthy, normal person. By placing the pulp of all the patient's finger tips on the patient's radial artery, the physician should move the patient's little finger toward his elbow and his index finger toward his thumb. When checking the patient's pulse, the physician should use his right hand; when supporting the patient's elbow, he should use his left [37]. The examiner's finger pulps should be smooth and soft, not harsh and rigid. In addition, the physician should not be experiencing any medical conditions that would interfere with his ability to concentrate during the examination. It is important for the patient and the physician to get adequate sleep and minimize outside distractions. In addition to closely monitoring the patient's pulse, the doctor should be observing the patient's eyes and facial expressions [38].

2.4.3 Examination of *Bawl* (Urine)

Since ancient times, doctors have employed urinalysis (or uroscopy) as a diagnostic technique [39]. According to ancient literature, urine is the end product of all digestive processes that take place inside the liver and blood vessels. The physiological functions and metabolic status of the liver, kidney, and conditions of other vital organs can all be immediately determined by carefully examining the urine. Additionally, urine also reveals information regarding other systemic diseases [40]; physical examination of urine is important which includes quantity, color, odor, consistency, foam or froth, clearness and turbidity, and sediments [41].

2.4.4 Examination of *Baraz* (Stool)

Additionally useful in the diagnosis of many disorders is the physical examination of stool. During a physical examination, the existence of foreign bodies is looked for as well as their color, amount, consistency, and size [42].

2.5 Line of Treatment in Unani Medicine

The management of diseases in the Unani system depends on the pathology involved in the disease process. The basics line of treatment is shown in Fig. 3:

2.5.1 Removal of the Causes

The pathophysiology of the illness or exact causes must be identified and removed by following a suitable regimen for optimal disease management [43].

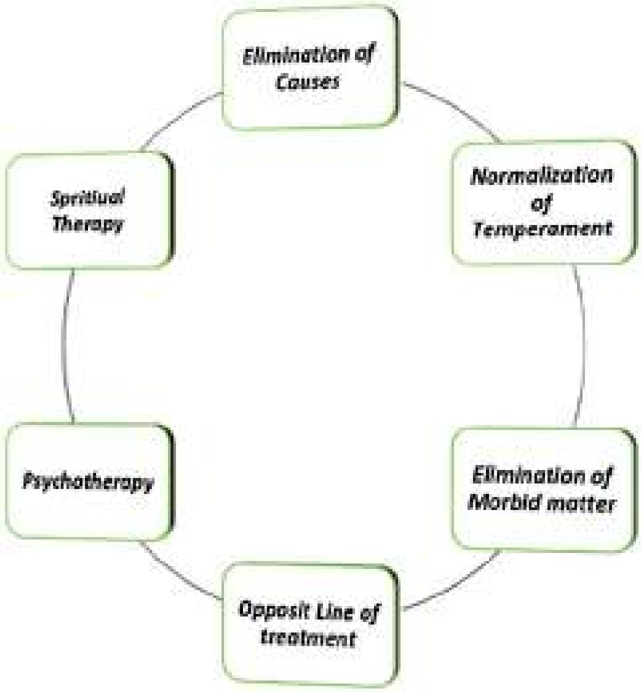

Fig. 3 The principles of treatment in Unani medicine

2.5.2 Normalizing of Alter Temperament

When an illness alters a person's normal temperament without affecting quantity or quality of humor, all that is really needed is for the temperament to return to normal. It may be corrected by only altering a person's lifestyle, or by using an appropriate regimen or medication to treat the sickness [43].

2.5.3 Elimination of Morbid Material

A variety of therapies are used to treat the diseases when a change in temperament results from the quantity and quality of morbid materials accumulating in the body, including concoction, purgative, vomiting, cupping, Venesection, and leeching therapies [44].

2.5.4 Opposite Line of Treatment

The administration of a regimen or medicine whose temperament is opposed to the illness is the fundamental therapeutic principle of the Unani medicine in order to cure morbid temperament and treat illness [45].

2.5.5 Holistic Approach

Specific habits, the surrounding environment, and the patient's physical, emotional, temperamental, and humoral state, as well as the health of the vital organ, are in consideration while treating the diseases. Also, it is important to consider the body constitution, the correct diagnosis, and course of therapy for better treatment.

2.5.6 Psychotherapy

Unani medicine uses herbal remedies, counseling, and changes to body-mind functions, such as sleep and eating habits, to treat mental illnesses. By maintaining a healthy lifestyle by incorporating the six essential components, one can promote the recovery of both physical and mental disorders [46].

2.5.7 Spiritual Treatment

Through its knowledge of the *Ruh* (spirit), which is regarded as the ultimate regulator of the human body, the Unani System of Medicine has evolved to recognize the relevance of spiritual health and therapy. One of the basic tenets of Greco-Arabic medicine is the notion of the reciprocal relationship between the soul and the body. Greek-o-Arabic medical experts gave a full explanation of how these two aspects of the human being interact, and they subsequently used this information to improve patient care. The patient's mental and spiritual well-being should always be given top priority by a doctor because the soul and the body are reciprocal. According to *Al-Razi*, "the doctor, even though he has his doubts, must always make the patient believe that he will recover, because the state of the body is linked to the state of the mind." Inspiring the patients to avoid negative emotions like grief and fear and getting them involved in joyful pursuits like chest games and hunting can all help them recover more quickly. Psychosomatic therapies, according to Unani doctors, are commonly used as actual treatments [47].

2.6 Therapeutic Approach in Unani Medicine

The initial method to treatment comprises the creation of a routine to normalize and balance the external or environmental variables (such as air, water, and food) involved in ailments and diseases. Other methods, such as treatment with natural remedies, may be suggested if this turns out to be in morbid matter. For pharmacotherapy, a different course of therapy or drugs with a specific temperament is used to treat particular ailments [48].

Figure 4 depicts modes of treatment in Unani System of Medicine:

2.6.1 Regimenal Therapy

It also called *Ilaj Bit Tadbeer* (Ilaj means "therapy" or "treatment," and *Tadbeer* signifies "regimen" or "systematic plan"). Consequently, *Ilaj Bit Tadbeer* refers to a course of therapy that attends to the ill person while maintaining general health. Regimenal therapy mostly consists of nonpharmacological strategies that regulate how people's lifestyles are changed for the purpose of disease prevention and treatment [49]. Ancient Unani physicians described numerous regimens for the care of illnesses, either by itself or in conjunction with other remedies. Classical

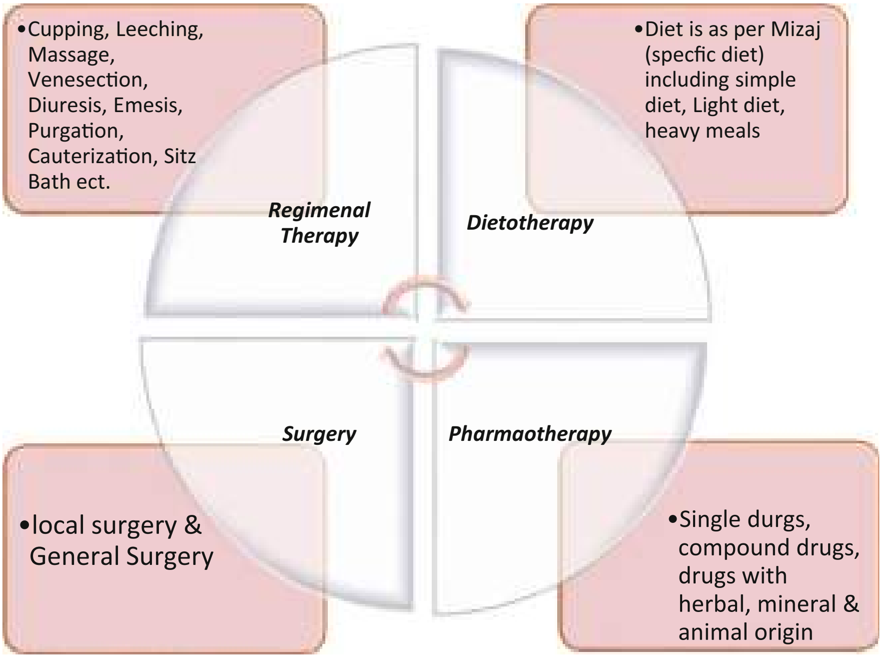

Fig. 4 Modes of treatment in Unani System of Medicine

writings for the eradication of the body's diseased humors or their diversion are referenced in the following regimens.

(a) ***Munzij w Mushil* (Concoction) therapy:** This method of healing is highly effective in managing chronic illnesses such as arthritis, fevers, obesity, diabetes, etc. For all chronic illnesses and illnesses more than 40 days, or acute illnesses more than 7 days, the Unani scholars *Jalinoos, Raban Tabri*, and *Razi* highly prescribe the concoction followed by purgation. Duration of concoction therapy depends on the humor involved followed by *Tabreed* (cold regimen). *Tabreed* is compulsory to avoid any unwanted adverse effect of purgatives and also to bring normalcy in temperament [50].

(b) **Cupping therapy**: Due to thousands of years of clinical experience in Unani medicine, the use of cupping therapy (*Hijama*) and detailed procedure with proper indications and contraindications are very extensively documented. Classical texts categorize CT into three main categories [51]:
   - One is Wet cupping Therapy (WCT) or cupping with bloodletting called Hijama bil-shurt in Unani medicine.
   - Second is Dry cupping Therapy or cupping without bloodletting called Hijama bila-shurt.
   - Third is Fire cupping also called Hijama-e-Nariya.

(c) **Massage:** The two primary mechanisms of action of massage indicated in the traditional Unani literature are, respectively, the evacuation of morbid matter and the diversion of morbid humors [52].

(d) **Leech therapy:** It is also called *Irsale Alaq* (Leech or Hirudo therapy); it is a bloodletting technique that entails the removal of a significant amount of blood from the body with the help of medicinal leeches for the prevention and treatment of numerous ailments [53].

(e) **Venesection:** In the Unani medical system, *Fasd*, or venesection, is a traditional and antiquated form of treatment. The Arabic term for "to open" is called "*Fasd*." Complete evacuation occurs throughout this phase, draining blood and dominant humors from veins. Most bloodletters reach a vein in an arm, leg, neck, or other area of the body using a small, delicate tool called a lancet. Then, after securing the region with a tourniquet and gently grasping the lancet between their thumb and fingers, they pierce the vein either lengthwise or diagonally. Through a perpendicular cut, the blood vessel is severed. They put the blood in measuring basins made of excellent Venetian glass that is expertly crafted [54].

(f) **Emesis:** Vomiting is referred to as "*Qay*" in the Unani medical system, and historically, Unani physicians have employed this procedure to heal many diseases. *Qay* is an effective and simple treatment. The medications used for these purposes are known as emetics, they either stimulate the stomach and cause reverse peristalsis or stimulate the location where vomiting occurs, and certain emetic prescriptions are required in order to treat a given sickness and provide the intended results. It is one of the best regimens to evacuate bilious and phlegmatic morbid matter, particularly from the liver and stomach. Along with its preventive advantages, it also has a number of therapeutic uses, including in cases of melancholia, vertigo, hemiplegia, jaundice, sciatica, and gout, among others [55].

(g) **Diuresis:** It is a regimen for eliminating waste from the body through urination. In a variety of medical conditions, this route is used to evacuate morbid matter or waste product. When diuretic drugs are added to a treatment plan to treat conditions like ascites, vertigo, back pain, joint pain, etc., it works best [56].

(h) **Enema:** The best way to treat colicky abdominal pain, diseases of the kidneys or bladder, and other inflammatory conditions of the abdominal cavity is to administer an enema through the anus, which is the best way to remove feces and other morbid matter from the intestines [57].

(i) **Diaphoresis:** Sweating serves as a form of bodily waste product elimination. This is accomplished through various techniques like hot fomentation, hot baths, hot poultices, exercise, massage, and also by introducing some specific herbs. This routine is also beneficial for boosting skin nutrition and lowering body temperature in cases of fever [58, 59].

(j) **Diversion of matter:** The Unani system defines *Imala* as the diversion of diseased matter, which may be present in vital organs and may harm the body's basic functions if it accumulated. There are two different types of diversion, one of which drives morbid humors toward the distant organ and the other toward the nearby organ. In this instance, when the morbid humors have just gathered and are not agitated in one organ, they are diverted to the next organ, and vice versa [58, 59].

(k) **Sitz bath:** One method of bathing involves immersing the lower body, particularly the hips and buttocks, in water with or without medication. This regimen is useful in the treatment of diseases of the gastrointestinal, rectal, anal, prostate, kidney, urinary bladder, urethral, testicular, vaginal, and uterine systems. Four various forms of sitz baths, including hot, cold, moderate, and compound (alternating hot and cold), are widely used for treatment [60].

(l) **Turkish bath:** The Unani system has used the *hammam* for millennia. In a typical *hammam*, there should be four separate compartments, each with a distinct temperature. For instance, the first, second, third, and fourth chambers should all be at various degrees, ranging from warm and hot to cold and normal. The hammam's hot water and air are beneficial to the body since they warm and moisturize the skin, respectively. The body is refreshed by this regimen, which also enhances hunger and allows waste to be expelled through the skin [61].

(m) **Irrigation:** In this procedure, the disease portion is irrigated with a medicated decoction or oil from a height above. A small amount of the medicine may pass through the skin and help in evacuating morbid matters. According to *Ibn Sina*, this regimen is particularly effective in treating a wide range of disease conditions, including head illnesses [62].

(n) **Fomentation:** As part of this protocol, the medicine powder is heated while wrapped in a cotton cloth before being applied locally as a fomentation to reduce inflammation and discomfort of a particular part. Unani pharmacopoeias include a number of formularies for the treatment of various illnesses using hot and cold fomentation [63].

2.6.2 Dietotherapy

The word "diet" comes from the Greek word "diaita," which denotes a way of life. It is described as both liquid and solid food items that are regularly ingested during daily life or as a prescribed amount of food that has been specially prepared for a certain illness or condition of health [64]. It is specifically used to maintain or restore strength, vigor, and vitality when they have been compromised by illness. To recognize the relative usefulness of foods in treating disease, one must first understand the quality and quantity of diet. For example, a wide variety of food products are known to have diaphoretic, laxative, or diuretic effects [65]. Different dietary classifications have been established to classify these foods according to their nutritional value, which includes light and soft diets, extremely nutritious diets, less nutritious diets or highly nutritious diets in moderation, and good diets that promote the production of chyme. Many of the nutritional products that have been described as medicines in classical texts, such as *Gulqand*, *Halwa*, *Murabba*, whey, vinegar, barley water, and mutton soup, are frequently administered either by themselves or in combination with other medicinal substances. The importance of nutrition in the Unani System of Medicine is highlighted by this all-encompassing approach to diet [66].

2.6.3 Pharmacotherapy

It is called *Ilaj Bil Dawa* in Unani medicine, in which single or compound formulation is used for treatment of various diseases. In view of Unai doctors, this therapy approach is one of the most successful because it is natural, environmentally safe, and less invasive. Pharmacotherapy may also produce good results when it is combined with various regimens or specific diet. The choice of medications for any given treatment is based on three fundamental ideas. First is drug quality in terms of temperament, second is drug quantity in terms of weight and potency, and third is administration time. The type and nature of the condition determine which medication is best. The type of affected organ, the severity of the illness, and other relevant variables including sex, age, weight, habit, habitat, season, prior therapy received, and disease stages all affect the weight and efficacy of the medication [67]. The Unani pharmacopoeia has about 2000 medicines derived from many sources, including plants, minerals, and animals. The classical writings of Unani medicine contain specialized methods for processing herbs, minerals, animals, and poisonous drugs. A range of dosage forms, including powders, decoctions, infusions, pills, and semisolid preparations like Majoon and Jawarish, are also covered in detail, along with the dosage and timing of consumption [68].

2.6.4 Surgery

Since ancient times, the Unani System of Medicine has always included surgery as a kind of treatment. A book named *Kitāb al-Taṣrīf li-man ʻajiza ʻani'l-Taʻlīf*, written by Arab Unani physician *Abul Qasim Zahrawi*, was composed of 30 volumes and covered issues in medicine, surgery, pharmacy, and other health sciences. The final volume, which has 300 pages, is devoted to surgery [78]. For the first time in medical history, he treated surgery as a separate subject. He discussed a number of treatments, innovations, and techniques, including tonsillectomy, tracheotomy, craniotomy, caesarean section, dentistry, and the removal of kidney stones and cataracts. Antiseptic drugs, styptic drugs, and other categories of medications are utilized in cases requiring surgical interventions according to the Unani System of Medicine [69].

2.7 Drugs and Dosage in Unani System of Medicine

2.7.1 Drug Source

There are three types of natural medicines: those derived from plants, minerals, and animals. According to its origin, Unani medications are categorized into three categories [70]:

(a) Plant-based medications use ingredients like roots, stems, bark, leaves, flowers, seeds, fruit, gum, resin, and extract, among others.
(b) Different metals, metal ores, and nonmetals in their natural forms are used in mineral origin medications.
(c) Animal origin medicines involve animal glands, tissues, and occasionally animal poisons.

2.7.2 Dosage Forms

The dosage forms were developed with the intention of satisfying all of the core objectives of pharmaceutical processing, including palatability, assimilability, stability, and an increase in safety and efficacy. In the Unani System of Medicine, drugs are typically used in four different forms: solid, semisolid, liquid, and vapor [71].

Pill (*Hab*), tablet (*Qurs*), powder (*Safuf*), and other solid dosage forms are available. Semisolid dosage forms include *Jawarish, Majoon, Khamira, Lauq, Itrifal*, and others. Decoction (*Joshanda*), infusion (*Khisanda*), distillate (*Arq*), syrup (*Sharbat*), drops (*Qatur*), and others are liquid medication forms. Vapor dose types include fragrances, *Lakhlakha*, steam inhalation, and fumigation. Unani doctors can also provide medication through pessary, suppository, liniment, Sitz bath, etc.

Kushta are also utilized to treat a variety of diseases. *Kushta* are fine powdered medical preparations made by calcining pharmaceuticals of metal, mineral, and animal origin with enhancing and correcting herbs, which transform them into organic forms that are biologically assimilable. The word *Kushta* derived from the Persian word *Kushtan*, which means "to kill," refers to all of the aforementioned changes. It should be mentioned that adding herbs recommended by the Unani System of Medicine results in extra benefits. Some of the therapeutic uses of *Kushta* are given as follows [72]:

- *Kushta-i Jast* showed hepatoprotective activity in CCl_4-induced liver damage.
- *Kushta-i Shibb* elicited protective action against myocardial infarction in rats.
- *Kushta-i Hart̠āl* is found effective in diabetes.
- *Kushta-i Nuqra* exhibited analgesic activity against chemical, thermal, and electrical noxious stimuli.
- *Kushta-i Ṭilā Kalān̠* (Unani gold preparation) augmented cell-mediated and humoral immunity.

2.7.3 Specific Processing of Drugs

The toxicity and danger of medications derived from plants, minerals (metals), and animals were known to Unani scholars. However, they can be sufficiently treated to make them safe for therapeutic usage [72]. Comparative pharmacological examinations of dangerous medicines such as arsenic, strychnos nux-vomica, aconitum napellus, etc. in their natural and processed forms have shown that the processed forms almost completely lose their toxicity when compared to the unprocessed, natural form. In the Unani System of Medicine, processing has goals that go beyond detoxification, such as improving efficacy and pharmacokinetic optimization, which involves achieving the desired rate of absorption and transport to the target tissue, among other things. The Unani System of Medicine has produced a tremendous amount of novel processing procedures. Several of the key methods are Burning (*Ihraq*), Bathing (*Ghasl*), Roasting (*Tahmis*), Frying (*Taqliya*), (*Tashwiya*), Purification (*Tasfiya*), etc. [73].

2.7.4 Corrective Drugs

The doctors of the Unani System of Medicine were aware of a variety of potential medication side effects (ADR) [72]. As a result, when explaining the properties of pharmaceuticals, they included their potential side effects as well as their corrective drugs. For instance, the commonly used laxatives *Operculina turpethum* L and *Citrullus colocynthis,* which cause tenesmus, are remedied by adding *Zingiber officinalis*. Similarly, the antiaging drug *Aloe barbadensis miller* induces intestinal abrasions and tenesmus, which are treated by *Sterculia urens* [74].

2.8 Prevention and Management of Diseases by Six Essential Factors in Unani Medicine

The six essential factors, whose suitable use in a person's life is decided by their temperament, provide one of the outstanding examples of the observational and philosophical genius of the Unani System of Medicine. As a matter of fact, the Unani System of Medicine identifies all the factors that affect health and sickness, classifying some as essential and others as nonessential [75].

The scope of the essential factors is exceedingly broad, and their inventive uses or rectifications are much more numerous. For instance, clean, abundant air is crucial for healing; therefore, homes should be roomy and cities should have adequate security. Contrarily, unavoidable issues can be dealt with by employing corrective factors [76].

The second aspect is "Movement and Rest," which are essential for good health and should be done in accordance with one's temperament. Movement can be active or passive; even someone who is paralyzed can engage in swinging, a practice that serves as exercise. In addition, exercise is necessary for all organs, including the senses, including the eyes, which should be used to look at lovely items, scenes, and complicated patterns, and the ears, which should be used to listen to music and songs. This demonstrates the brilliance of Unani scholars who discovered several elements and straightforward classification techniques that could group them into a manageable number of categories for easy application. Figure 5 illustrates the six essential factors impacting the overall management of disease state in patients [77].

2.9 Historical Evaluation of Unani Medicine and Contribution of Greek, Arab, and Indian Physicians

2.9.1 Unani Tibb in Greek Origin

The Unani System of Medicine, as indicated by its name, has deep-rooted Greek origins, with a historical journey that traverses through Egypt and Mesopotamia, ultimately embraced and enhanced by the Arabs [78]. In India, Unani medicine gained prominence, thanks in large part to influential physicians like *Hakim Ajmal*

Fig. 5 Six essential factors in Unani medicine

Khan, who skillfully adapted its principles to the local geographical and human context, making it one of the most significant traditional medical systems in the country. Unani medicine also demonstrated its commitment to progress by delving into molecular research in the 1920s to understand the molecular impacts of its treatments. Additionally, it successfully institutionalized medical practices through the development of curricula, organizations, and professional bodies [76].

The botanical foundation of Unani therapy finds its origins in ancient Egypt, where the use of plants in medical treatment was highly esteemed. The Egyptian culture's proficiency in surgery and medicine is evident in the historical papyri studies. Renowned Egyptian physicians like Amenhotep (1550 BC) and Imhotep (2800 BC) left their mark in the annals of medical history. Mesopotamia, too, made significant contributions, as evidenced by their diagnostic instruments for testing urine and stool samples. The Greek era of Unani medicine was initiated by Asclepius (*Asqalibus*, 1200 BC), a prominent physician and scientist who laid the foundation for the Greek approach to Unani medicine. During this era, the Greeks synthesized medical knowledge, drawing from Egyptian and Babylonian medical expertise, and began shaping the art of medicine [79].

(a) ***Buqrat*** **(Hippocrates):** The leading physician throughout the classical era of Unani medical history was Hippocrates (460–370 BC). He chronicled the current medical knowledge and placed an emphasis on the natural causes of disease in order to provide the groundwork for the development of medicine as a disciplined science. Observation, experience, and logical concepts were the three pillars of Hippocratic medicine, and they are still relevant in the fields of science and medicine today [80].
(b) ***Jalinoos*** **(Galen):** Galen was a Roman Greek physician, surgeon, and philosopher. Galen had an impact on the development of various scientific domains, including anatomy, physiology, pathology, pharmacology, and neurology as well as philosophy and logic. Galen is recognized as one of the most accomplished of all ancient medical specialists. Galen, a physician, was the first person to use the pulse as a sickness symptom. Representative research fields include urology, neurology, myology, respiration, reproductive medicine, and neurology [79, 80]. He advanced drug research and clinical use. He discussed the heart's valves, named the seven unique pairs of cranial nerves, and pointed out the structural differences between arteries and veins.
(c) **Dioscorides:** The first author of the illustrated book De Materia Medica (*Kitab al-Hasha'ish*), which contains 600 herbal remedies, was a man with a vast understanding of medicinal plants. With the exception of Dioscorides original additions, the book included all prior knowledge of pharmacology [81].

2.9.2 Arab Physician Contribution in Unani Tib

Following the fall of the Greco-Roman civilization, the expansive *Arabic*-speaking region of the Middle Ages made significant contributions to human knowledge, particularly in the realms of science and medicine. The translation of Unani medical texts into Arabic began in the *Umayyad* era but gained widespread popularity during the early years of the *Abbasid* century. Between 750 and 850 AD, a period of intensive translation efforts was succeeded by the publication of original Arabic works authored by scholars in the region [82].

Arabian physicians conducted extensive philosophical and scientific research, critically examining existing medical knowledge while contributing new insights to the field. They achieved remarkable advancements in various disciplines, including philosophy, general science, technology, and, notably, medicine, which they revolutionized [83]. Prominent figures during this era included *Ibn Sina, Abu Sahal Masihi, Zakariya Razi,* and *Rabban Tabri,* all of whom were exceptional physicians [79, 80].

One notable achievement was the creation of the "*Materia Medica*," a comprehensive compilation of 1400 drugs, greatly influenced by the work of *Ibne Baitar*. In the field of chemistry, *Jabir bin Hayyan* made significant contributions. Additionally, a pioneering figure in the realm of eye surgery, *Hunain bin Ishaq*, advanced the field with cutting-edge treatment methods, laying a solid foundation for ophthalmic surgery [84].

The progress in surgery can be better appreciated by examining the work of the Spanish Unani scholar *Abu-al-Qasim Zahrawi*, particularly his treatise *"Kitab* *al-Tasrif*." Furthermore, the Arabs' contributions extended to the development of obstetrics and pediatrics, which became distinct fields of study. Arab scholars conducted research and authored books on these subjects, further enriching the corpus of medical knowledge during this transformative period [85].

Ibn Zuhr and *Ibn Rushd*, two other Spanish scholars, helped establish Unani medicine in Europe. Numerous books were written by *Ibn Zuhr*, also known as Avenzoar, including "*Kitab al-Iqtisad*" (*Book of Moderation*), "*Kitab al-Aghdhiya*" *(Book of Aliments),* and "*Kitab al-Taysir fi al-Mudawat wa al-Tadbir*" *(Book of Facilitation on Therapeutics and Dietetics).* "*Kitab al-Taysir fi al-Mudawat wa al-Tadbir*" *(Book of Facilitation on Therapeutics and Dietetics),* one of these compilations, is to evaluate his contributions to the development of surgery. He did postmortems on sheep as part of his clinical study on the management of ulcerating disorders of the critical organs and underlined the importance of providing surgical trainees with a full and practical anatomy instruction [85]. He proposed the idea of a training program or internship for medical students to address this. Additionally, he indicated when a doctor should quit treating a surgical problem and drew a line between a general surgeon and a general physician. By proposing a variety of novel diseases and treatments, he contributed to the improvement of surgical and medical knowledge by developing the concept of pre- and postsurgery diet and management. Following this, the Unani system emerged in India [86].

2.9.3 Unani Scholars from India

The Unani System of Medicine, introduced in India in the seventh century, has undergone significant development and evolution spanning over 1200 years. Throughout this lengthy history, countless researchers and scholars have contributed to its development, leading to its widespread acceptance among the population. The support of Delhi *Sultans* and *Mughal* emperors further solidified its position in India [79]. Adapted to the unique geo-human context of the nation, the Unani system has become one of the most effective and beloved Indigenous medical systems. Notable figures like *Muhammad ibn Yusuf Harwi*, in his work on geriatric care and antiaging therapy, explored various techniques and pharmaceuticals aimed at delaying the effects of aging. Influential proponents of the system, including *Ali Gilani, Hakim Alvi Khan*, and *Akbar Arzani*, made significant contributions through teaching, clinical treatment, and prolific book authorship. Ali Gilani's famous commentary on all five volumes of A*l-Qanun*, written during *Akbar's* rule, was frequently referenced by Unani scholars in Iran and the Middle East [87].

The underlying ideas and key practices of Unani medicine were created by the *Arabs* and Persians, but Indian scholars explained and applied them to a degree that was unsurpassed in the countries where it originated. In contrast to *Muhammad Najm-al-Ghani's* greatest Indian compendium, which was released in 1930 and contains descriptions of 2500 natural commodities, *Ibn Baitar's* ancient pharmacopoeia offers descriptions of 1400 medicinal plants and minerals [88]. By examining their therapeutic effects in line with Unani principles, new drugs created in India or modified from the Indian system of medicine, for instance, were introduced into the Unani System of Medicine. *Takmile Hindī*, a company founded by *Shāh Ahl Allāh*, serves as an excellent illustration of this venture. Existing medications' new effects were also identified*; Muḥammad Ḥusayn Shīrāzī* was a notable contribution to this [86]. In the realm of pharmacy, there have been several developments and novel drug formulations created, such as the delicately edible *Khamira* developed during the Mughal era [85]. Unani medicine, deeply rooted in historical tradition, has a rich history of addressing a diverse array of medical conditions, including immunosuppressive disorders such as HIV, syphilis, and gonorrhea. In India, numerous scholars, such as *Abd al-Fatah and Khwaja Rizwan Ahmad*, have authored approximately 100 treatises in Arabic, Persian, and Urdu, offering insightful interpretations of *Ibn Sina's* works [80]. Notably, the nineteenth century marked a period of remarkable innovation, exemplified by the pioneering contributions of *Hakim Azam Khan*, who made groundbreaking advancements in medicine and pharmacology within the Unani system [78].

During this time, a government organization in Hyderabad State played a crucial role in disseminating Unani references and textbooks. Influential educators like *Hakim Kabeeruddin* significantly contributed to the dissemination of Unani knowledge [79]. He worked diligently to translate old Unani texts from Persian to Urdu, harmonizing Unani philosophy with contemporary scientific concepts. This collaborative effort resulted in the creation of textbooks suited to the modern era. He also held important positions at institutions such as the *Nizamia Tibia College in Hyderabad* and the *Ayurvedic and Unani Tibia College in New Delhi* [81].

In the early twentieth century, Unani medicine embraced modern insights from molecular medicine while preserving its traditional philosophical foundations. Scholars like *Hakim Muhammad Feroz al-Din* incorporated contemporary prescriptions, shared their findings with the wider medical community, and encouraged Unani doctors to critically assess them. Their efforts extended to researching the molecular mechanisms underlying alternative therapies for later stages of healing and conducting comprehensive evaluations of Unani treatments, encompassing both positive and negative outcomes [86]. The late nineteenth and early twentieth centuries witnessed significant contributions from families such as the *Hyderabadi Nizam*, *Lucknowi Azizi*, and *Dilli Sharifi* family, further demonstrating the enduring relevance and progress of the Unani medical system over time [82].

The renowned educator and physician, *Hakim Ajmal Khan*, made significant contributions to the advancement of the Unani System of Medicine in India. He initiated a comprehensive effort to modernize the Unani system, bringing about significant changes in its academic, clinical, and research aspects. To create a prototype college for oriental systems of medicine, he extensively studied European medical institutions. This initiative resulted in the establishment of the *Ayurvedic & Unani Tibia College in Karol Bagh*, New Delhi, founded by Lord Hardinge in 1916 and inaugurated by *Mahatma Gandhi* in 1921. This unique institution remains the only one in India offering education in both *Ayurvedic* and *Unani* medical systems concurrently [87].

Following in *Hakim Ajmal Khan's* footsteps, the renowned physician *Hakim 'Abd al-Hamid* modernized Unani medicine production on a large scale [86]. He founded *Hamdard Davakhana*, a company dedicated to manufacturing high-quality Unani medicines for domestic and international markets. Additionally, he was instrumental in establishing the Institute of History of Medicine & Medical Research in New Delhi, later known as *Jamia Hamdard*. This institution has evolved over time into a multifaceted center with a distinguished faculty and a specialized Unani treatment hospital [88].

In the latter half of the twentieth century, *Hakim M.A. Razzaque* continued *Hakim Ajmal Khan's* vision, placing a strong emphasis on research and scientific endeavors. He played a pivotal role in shaping the structure of the Central Council for Research in Unani Medicine (CCRUM) and in establishing the National Institute of Unani Medicine in Bangalore [83]. Serving as the first director of the organization and as the Indian government's deputy Unani advisor from 1979 to 1991, he laid the foundation for the research in Unani System of Medicine in the country [87].

3 Conclusion

The use of traditional medicine in healthcare and disease management dates back to thousands of years since the earliest of civilizations. With the advent of new religions and beliefs, it has been both exalted and condemned. More than secular factors influence clinical presentation, diagnosis, course of therapy, formulations employed, and even the type of specialist seen in Unani medicine, not just in India but also globally. We anticipate that modernizing the documentation process for generating evidence while taking into account the epistemology and guiding principles of the system will undoubtedly help Unani medicine reclaim its rightful position among the contemporary world's healthcare systems and pave the way for a vibrant, forward-thinking, and promising future. Reverse pharmacology, pharmacoepidemiology, retrospective treatment-outcome surveys, and whole-system approaches are investigative techniques. Connecting the best aspects of Unani medicine to modern technological interventions, substantiated by in-depth studies and robust clinical trials, will help validate the therapeutic utility of Unani system. This chapter hopes to fuel research and documentation of scientific efforts done across the globe to propel this system as one of the mainstream medicinal systems. It also envisages attraction of new practitioners to develop an evolutionary approach in prescribing Unani medicine in routine clinical practice and recording observations of expected and unexpected clinical responses in a scientific manner backed by appropriate statistical analytics.

Xenobiotics in Traditional Medicine Practices and Quality Control Strategies

42

Baturh Yarkwan and Omiagocho ThankGod Isaac

Contents

Abstract

Traditional medicine has been recognized globally as an effective tool for managing an array of ailments that confront humanity. Before the advances in sciences that revolutionized the pharmaceutical industry, ancient civilizations were dependent on herbal preparations for their therapeutic needs and

occasionally even prophylaxis demands. The applications of Chinese medicine, for instance till date speak volumes to the therapeutic potentials of carefully crafted traditional medical practices. However, the pollution of agricultural fields owing to indiscriminate applications of agrochemicals has led to contamination of soils, water, air, and wildlife creating a vicious cycle of xenobiotics in the environment. Since herbal plants do not grow in isolation, they are often polluted with heavy loads of trace organic and inorganic pollutants circulating in the environment. The concentration of which may be dependent on the source of the plant, geographical location, proximity to source contaminants release point, topography of the area, flooding, industrial activities, and discharges, among other factors. Xenobiotics of unknown toxicity may be taken in especially by rural dwellers who depend largely on herbal preparations for their pharmaceutical needs. Since these preparations are not administered at scientifically determined doses, they constitute a considerable source of exposure to pollutants with associated adverse health effects and even death. This chapter reviews the state of pollutants in herbal preparations, their sources and potential threats on consumers as recently reported in the literature. It highlights quality control measures as a necessary approach to minimize the menace of xenobiotics contamination of herbal medicinal products. It concludes by proffering viable measures to arrest the presence of contaminants in herbal products. These measures, when taken, would hopefully increase the quality of herbal preparations and increase optimal utility while minimizing the hazardous effects arising from the presence of contaminants. From pleasure-seekers in sexual enhancers to weight-loss products for the obese to chronic medical conditions and microbial infections, botanicals have remained a regular companion in several homes on both sides of the rural-urban divides.

1 Introduction

Botanicals are a rich source of novel phytochemicals which carry pharmacological activities in biological systems [1, 2]. These have often been employed as the only source of medicals for rural dwellers. The modern man occasionally tends toward botanicals to meet his needs, owing to the rich presence of phytochemicals and nutraceuticals with desirable bioactivities [3, 4]. Humans' quest for botanicals varies with their needs. Pleasure seekers may go after sex-enhancers, while those desiring to lose weight patronize slimming herbal medicinal preparations [5–7]. Sufferers from microbial infections seeking relief against an array of pathogenic microbes of varying genetic composition, inflicting different medical conditions with a range of pathophysiological presentations, also depend on botanicals [8–11].

The ancient man depended upon herbs to cure himself of his ailments. The active ingredients in herbs are often the starting materials of refined pharmaceuticals, or aid as a guide in the chemical synthesis of similar active ingredients or more potent compounds through modifications of original isolated bioactive molecules [12]. The acceptance and patronage of herbal preparations among urban dwellers is growing [13] even among medical practitioners in the developed nations [14] as well as medical students [15] thereby leveling the steep slope that hitherto existed between consumers of rural and urban dwelling. Some of the factors attributed to increased herbal use in the global south include low socioeconomic status, long travel distance between patients' houses and locations of health care facilities, level of education, and inadequate health insurance coverage [13, 16]. On a comparative basis, the rural dwellers show more propensity of depending on Traditional Herbal Medicine

(THM) than the urban dwellers. Hughes et al. [17] reported the odds of dependence on THM are 12-to-1 against the rural dwellers. Among the several predisposing factors, sex, age, and religious affiliation present inconsistent pattern to account for herbal patronage or otherwise [18].

The global consumption of herbal medicinal preparations is high [3] thus, it is important for it to be monitored for public health concerns. These can be achieved through stringent quality control measures and increasing education and endorsement of medical practitioners [14] around the importance of Traditional Herbal Medicines (THMs) and relevance of quality of the products being sold. Sadly, these products are contaminated with xenobiotics of varying nature, sources, and concentrations [19–21]. With most people estimated at 80% from emerging economies meeting their health needs through THM [3, 12], it is imperative to ensure the safety of these consumers through ensuring highest quality THMs, thereby preventing further health complications which would worsen pressures on already fragile and overstretched health care systems and maximizing the benefits from THM. Thus, it is important to understand this nexus-presenting situation, to be armed in the choice and use of herbal products while avoiding the contaminants and their attendant adverse side effects. This is a multifaceted task encompassing producers, regulatory agencies, consumers, and advocates such as academia and civil society organizations. The objectives of this chapter are to demonstrate the global use of THMs, elucidate the presence of xenobiotics in these products and trace their sources, and then discuss the quality control measures that could be employed to ensure healthy THMs are available for all consumers.

2 Global Patronage of Herbal Preparations

The application of medicinal plants for therapeutic purposes is as old as human history, and spreads across the globe. It has remained an important part of trado-medical practice till today. Data shows that about 80% of the world's population rely on herbal preparations for their primary health care demands [2, 3, 22]. The medicinal values of medicinal plants are attributed to their phytochemical content. The most important of these phytochemicals include alkaloids, flavonoids, tannins, and phenolic compounds [23]. In the last decades, the surge in demand for THMs industrial products has produced a corresponding increase in the circulation of a large variety of products in the markets useful to both complementary and alternative medicine [3]. According to a WHO report, herbal medicines represent approximately 20% of the total drugs marketed globally. The total global market worth of herbal products is estimated at over US $72 billion as at 2020 [24]. Additionally, it is projected that the percentage of plant-derived prescription drugs is a least 25% of total prescription drugs in the market [21]. Medicinal plants are a good source of various natural antioxidants notably used for the treatment of diverse diseases worldwide [25]. Botanicals, or their products, have been employed in the prevention and treatment of several chronic diseases such as arthritis, cardiovascular diseases, diabetes, inflammatory diseases, and other ailments [26]. They have also been reported to possess antimicrobial potential [27]. Furthermore, the problems of the extreme cost of synthetic drugs, besides the residual effects on livestock products, adverse effects, and evolution of drug resistance genes in pathogenic organisms have led researchers to continue searching for powerful, safe, unconventional, and economically friendly natural drugs of plants and animals origin.

2.1 Economic Potentials of Herbal Preparations: The Case of Traditional Chinese Medicine

Traditional Chinese medicine (TCM) is reported as an important characteristic of Chinese culture and medical tradition for thousands of years now [28, 29]. Nowadays, Traditional Chinese medicine has gone beyond the borders of Asia and has become internationalized. It is now often combined with orthodox single-target drugs to attain complete cure of complex diseases [30]. For instance, its being a long time now since the WHO recommended artemisinin combination therapy as an important management procedure for malaria [31]. The proceeds of traditional herbal medicine (THM) have been projected to reach trillions of dollars before 2028 [32]. The growing popularity of traditional and herbal medicine raises the important question to its likelihood of contamination and the prospects that long-term exposure to such contaminants could result in threatening health concerns [33, 34].

2.2 Risks and Challenges Associated with Herbal Preparations

The increasing demand and the pressure to meet with sufficient supply has influenced THM productions. This is accompanied by either unintended or even intentional contaminations to increase quantity hence maximizing profit [1, 35]. Contamination of herbal products by potentially toxic elements could arise from pollution of food supply chain processes. These include the growing conditions, the harvesting procedures, and the storage techniques [28, 36]. Moreso, the increasing popularity of herbal medicine throughout the world has led to increasing fraudulent practices along with possible negative effects due to contamination, adulteration, or misidentification of plant species [1, 35] and those linked to the natural toxicity of the plants [37, 38]. Because of the increased demand from consumers, there is enhanced urgency to assess the potency of the products to ensure they are safe for the consumers [19]. In addition, the risk of adverse effects due to the presence of xenobiotics such as pesticide residues, heavy metals, etc., or microbiological contaminants mandates close toxicological assessment to eliminate potential safety concerns [19].

3 Xenobiotics: Definition and Scope

Xenobiotics refers to "chemicals found but not produced in organisms or the environment." These are compounds of synthetic origin which maybe present in trace concentrations and/or high concentrations, often used to service domestic, industrial, pharmaceutical, and agricultural demands whose residues may remain in the environment. The technological revolution observed by the twentieth century resulted in the manufacturing of several compounds targeted at improving daily life such as antibiotics, agrochemicals (fertilizers, pesticides, and all the other agrocides), dyes, pharmaceuticals, and personal care products (PPCPs), additives, etc. These compounds may not be found naturally occurring in the environment or occur naturally at concentrations markedly peculiar from those resulting from anthropogenic activities [39]). Xenobiotics are characterized by their physicochemical characteristics, such as ionizability, small molecular size, hydrophilicity, lipophilicity, volatility, and polarity, which makes their identification, quantification, and removal a tedious task [39]. The term xenobiotics also describes some naturally occurring chemicals present in the environment at an excessively high concentration [40]. Xenobiotics may be obtained in water, soil, plants, air, animals, and in even humans owing to direct contact or transfer through different medium and food chain. They are classified as biocides/pesticides, pharmaceuticals, illicit drugs, personal care products, and wastes [41] (Fig. 1).

Xenobiotics may also be categorized according to an array of factors. These may include physical state, uses, nature, and physiological modulatory effects. Moreover, their impacts on the environment and by extension humans' health are of great concern since protracted contact with even minute concentrations may give rise to toxicities evident by mutagenic, carcinogenic, or teratogenic effects [39]. Due to the increase in population growth and the rise in urbanization, several human activities have led to widespread environmental contamination by xenobiotics of different kinds. Thus, the high demand for pharmaceuticals cum the increasing population growth has placed the public at risk of exposure to xenobiotics. In addition, the development of illicit drugs has further led to the release of harmful pollutants into the environment. The outcome of this environmental pollution posed numerous short- and long-term consequences on the natural ecosystem.

3.1 Reported Xenobiotics Found in Herbal Preparations

Xenobiotic toxicity is a great threat to traditional medical practice and the use of herbal plants. It greatly impacts the quality of botanicals as starting materials, herbal extracts, and the safety, and consequently the marketability of THMs. Thus, effective quality assessment and control of foreign chemicals (xenobiotics) present in herbal plants used in food industries, pharmaceuticals, and traditional medical practice have become indispensable [42]. Although the use of THMs has witnessed a marked increase in developed countries over the last decades, many health dangers could be

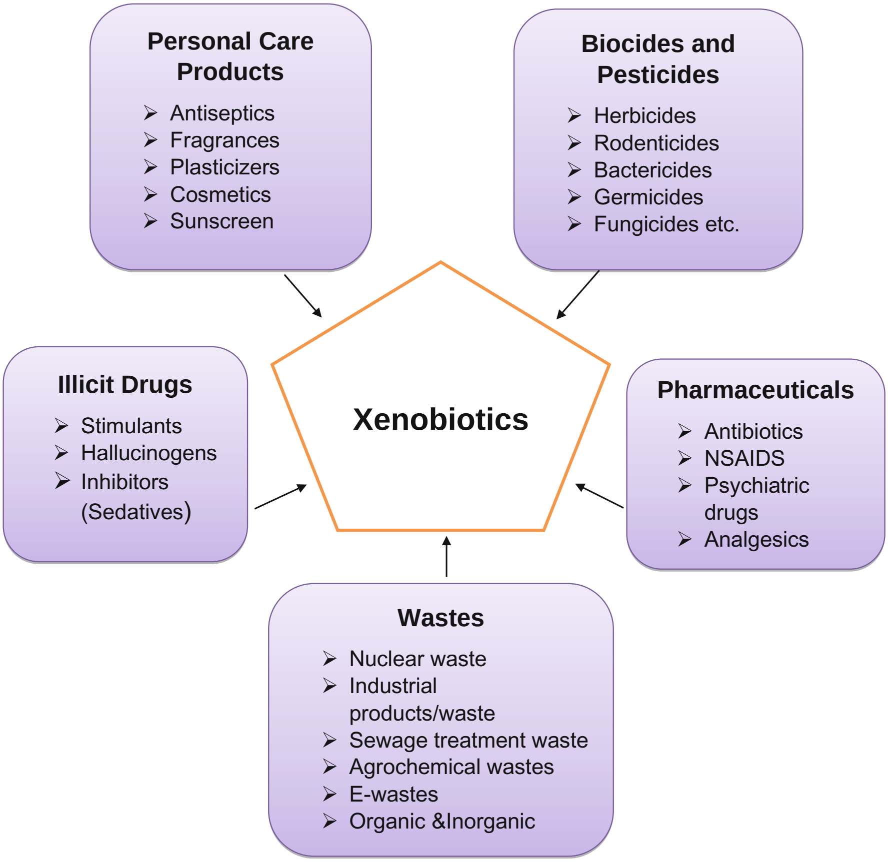

Fig. 1 Sources of xenobiotics

attributed to the THMs and their mixtures due to the contamination of agricultural soil, underground water, and even atmosphere [43–45].

Heavy metals including Nickel (Ni), Aluminum (Al), Lead (Pb), Cadmium (Cd), and Arsenic (As) which occur naturally in the environment have the potential to accumulate in both plants and human organs. According to the Environment Protection Agency, these metals are the commonest heavy metals associated with environmental pollution [46]. It has been well-documented that soil may be contaminated with these toxic metals due to processes such as automobile and industrial emissions, polluted irrigation water, atmospheric dust, and the use of agrochemicals (pesticides and fertilizers). The pollution of the environment ultimately results in the contamination of botanicals of herbal value [47]. Accordingly, the WHO has long emphasized the necessity of the quality control assessment of herbal products, such as heavy metals analysis [48]. In a recent study to examine the extent of herbal contamination by heavy metals using Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES), 25 pharmaceutical herbal products for infants and

15 traditional herbs used in Jordan were analyzed. Al, Pb, and Ni were detected in 76, 88, and 4% of the analyzed samples of pharmaceutical herbal products and in 87, 93, and 13% of the analyzed samples of THMs, respectively [49]. The data obtained ranged within the acceptable limits of toxic heavy metals based on the World Health Organization (WHO) specifications. The results also proved the extreme use of medicinal plants as an alternative medicine should be embraced cautiously while considering the safety levels [49]. Some heavy metals have been detected above the maximum permissible daily limits with the heavy metals' concentrations found between 9.61 and 52.74 μg/g for Pb while Cd was from 0.19 to 1.75 μg/g in herbal products examined in Iran [50]. Another research by Kohzadi et al. analyzed the concentration of heavy metals in eight diverse types of THMs and eight dissimilar kinds of herbal distillates marketed in Sanandaj, Kurdistan, Iran. The author found that the THMs contained a significantly higher level of Fe, Al, Pb, Cr, As, Cd, Mn, Zn, and Ni ($p < 0.02$) more than the herbal distillates [20]. A summary of several other case reports in the past can be found in the article cited [49, 51]. Undoubtedly, a high level of exposure to these metals has detrimental impacts on human wellbeing, as several of these metals are associated with abnormalities such as cancers and damage to certain organs [36]. Lead for instance besides being recognized as a potential carcinogen may also accumulate in the gray matter of the brain thereby destroying red blood cells and inducing neuronal damage and loss of synaptic connections [3]. Some other metals such as Mn, Cu, Zn, Fe, and Cr are essential nutrients for the normal biological functions and supporting physiological processes of the human body. However, higher concentrations above certain permissible limits might lead to toxicity of vital organs in the body [52] Table 1.

Another route of contamination of medicinal herb relies on the use of agrochemicals. Excessive microbial growth, the presence of pesticides, and orthodox drugs have been widely reportedly found in some herbal products [55]. Asian traditional herbal medicines are the highest studied types of herbal product. To ensure consumer safety, maximum residual levels (MRLs) have been established for pesticides [56].

Table 1 List of some heavy metals, their sources, potential toxic effects, and their maximum permissible limits in foods [53, 54]

Toxic metals	Uses/sources	Toxic effects	Permissible limits (mg/l)
As	Pesticides	Skin diseases and lung cancer	0.1–0.2
Cd	Plastics, pigments, batteries, plating	Kidney damage, lung cancer, and bone disorder	0.05–2.0
Cr	Dyes, alloys, tanning	Liver and kidney damage allergic dermatitis, respiratory effects	0.05–0.15
Pb	Batteries, wire, and cable, alloy	Neurological effects, hematopoietic system damage, and reproductive effects	0.01–3.0
Hg	Chloro alkali industry, pesticides, thermometer, batteries	Neurological effects, kidney damage	0.05–1.0

According to research by Wang et al. to determine the presence of about 168 pesticides from analyzing 1017 samples of Chinese herbal medicines, 76.0% of the investigated samples contained multiple pesticides' residues, contrasting the small fraction of 10.8% which was free of the targeted pesticides' residues [57]. In another development, a recent publication summarizing the findings from routine inspection targeting organochlorine pesticides in Chinese herbal medicine, spanning over 10 years, 1665 samples for 37 kinds of Chinese Herbal Medicine were analyzed employing the Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) method, coupled with gas chromatography (GC) featuring electron capture detection (ECD). Based on Asian pharmacopeias acceptable maximal residue levels for organochlorine pesticides, pentachloronitrobenzene (PCNB) contamination of *Ginseng radix,* and the total dichlorodiphenylethanes (DDT) and PCNB contamination of *Panacis quinquefolii radix* presents critical issues to worry over. Chien et al. [58] observed that based on Korean Pharmacopeia residue limit, DDT level exceeded the Asian acceptable maximum residue levels by nearly 60% in *Panacis quinquefolii radix*. The exceeding rate based on Japan Pharmacopoeia was about 50% while based on the Hong Kong Material Medical Standard, the residue exceeded the limit by nearly 20%. In addition, the PCNB level according to the Pharmacopeia of the Peoples' Republic of China exceeded the Asian acceptable maximum residue levels by 40% for *Panacis quinquefolii radix,* and 30% for *Ginseng radix* [58].

Being one of the most patronized Chinese herbal medicines, chrysanthemum (*Dendranthema grandilora*) is widely engaged as a heart-cleansing herb and blood detoxifying agent, owing to its potent anti-inflammatory, anti-oxidative stress, as well as anti-tumor effects [59, 60]. Pesticide residues in comparatively high levels have been found in commercial chrysanthemum flowers and chrysanthemums [61, 62]. For instance, according to research by Feng et al., a count of 25 pesticides were observed with incidences of detection exceeding 10% in 75 chrysanthemum tea samples [63]. Commonly observed pesticides were carbendazim, bifenthrin, and imidacloprid having a detection rate of 91%, 68%, and 63% being the top three pesticides respectively [63]. Furthermore, in a quantitative analysis of multi-pesticide residues involving some 50 commercial chrysanthemum-tea samples, at least 5–13 pesticides' signatures were identified in 56% of samples [59]. The risk of pesticide contamination of herbal medicine presents a worrying situation all over the world, and there is need for a more focused attention toward quality assessment and control measures for herbal drugs.

Similarly, mycotoxins in plant material represent another potential health risk on the use of herbal drugs. Mycotoxins which are secondary metabolic products may be secreted onto or into medicinal plants by some species of fungi. There are non-volatile compounds with a relatively low molecular weight. The most reported mycotoxins in herbal products are those produced by species of fungi of the genus *Fusarium, Aspergillus,* and *Penicillium*. Aflatoxins, ochratoxins, fumonisins, and tricothecenes, are the four major groups of mycotoxins. There are highly neurotoxic, mutagenic, hepatotoxic, carcinogenic, teratogenic, immunotoxic, and nephrotoxic. Hence, their presence in medicinal plants and food products represents an interesting area of research. The International Agency for Research on Cancer classified

Aflatoxin B1 as a carcinogen of Group-1 standing and is the most toxic mycotoxin [55, 64]. Mycotoxin contamination of medicinal herbal products has been investigated by various research groups which have reported elevated content of mycotoxins beyond the maximum acceptable limits [65, 66].

3.2 Sources of Xenobiotics Found in Herbal Preparations: Focus on the Global South

Several anthropogenic activities account for the release of toxic xenobiotics into the environment, including Pharmaceutical and Personal Care Products (PPCPs) and their metabolites, cleaning products, surfactants, food additives, metalloids, microplastics, pathogens, livestock treatment and excretion, wastewater discharges from sewage treatment plants and industrial effluents, industries and production plants and associated industrial formulations, nanomaterials, rare earth elements, and of course a wide range of agro-industry related biocides [41]. Other sources of herbal contaminants of biological origin include bacteria and bacterial spores, viruses, yeasts, molds, protozoa (amoebae, helminths) nematodes, insects, and such other organisms as earthworms, acarus [67, 68]. The prevalence of microbial pathogens in herbal preparations could be high, posing as a further complication to public health concern especially for elderly ones. De Sousa Lima et al. [69] investigated 132 herbal preparations donated by users for microbial analysis. They reported 51.5% and 35.6% had bacterial and fungal growth, respectively while analyzed water samples showed 77.85 and 66.7% were positive for total coliforms and *E. coli*, respectively [69]. The predominantly observed microbial contaminants were *Salmonella* spp., *S. aureus*, *P. aeruginosa,* and *E. coli* with percentage isolates in the order of 49.2%, 34.8%, 25.8%, and 14.4%, respectively. Let's take a closer look at the sources of xenobiotics in herbal preparations.

3.2.1 Agrochemicals, Pharmaceutical, and Personal Care Products

Herbal drugs are known for containing pesticide residues, which may have accumulated due to exposure from agricultural practices, contact with contaminated soils during farming, such as spraying, and administering fumigants during storage [3]. The broad term Pesticides comprises chemicals used to eliminate pests and are classified as nematocides, fungicides, insecticides, herbicides, rodenticides, and others depending on their specific activities [3, 70]. Structurally, pesticides are categorized under organochlorine pesticides (OCPs) such as hexachlorocyclohexanes (HCH) and dichlorodiphenylethanes (DDT)]. Others include organophosphorus pesticides (OPs) such as malathion, dichlorvos, and parathion; nitrogen-containing pesticides such as atrazine and propazine; pesticides derived from plants such as rotenoids and pyrethroids, among others. Between 1990 and 2016, the surge in the application of pesticide-active ingredients per unit of cropland attained 75% increase according to UNEP Report on Pesticides and Fertilizers [71]. The database for European Union pesticides consists of about 1426 pesticide active ingredients out of which only 476 are currently approved for use, 901 of the ingredients are banned, and 49 are still pending approval [72]. Pesticides whose application is directly to the soil may be carried by rainwater run-offs into water bodies such as rivers while others may yet percolate into the groundwater. Pharmaceutical and Personal Care Products consumed by humans are metabolized into different metabolites, among which there may be derivatives whose toxicities may exceed that of the parent molecule(s) and, upon release from the body, they get into environment [41]. After excretion, toxic metabolite ends up in sewage/wastewater treatment plants from where there are partially removed through treatment and then eventually dumped in receiving water bodies such as lakes, rivers, oceans, as well as other environmental matrices such soil, groundwater, etc. Agricultural soils can also be polluted by the unsuitable disposal of unwanted or expired pesticide packaging, pesticides, and during cleaning of application equipment [43]. Alternatively, it could be by accidental discharge of pesticides from damaged containers, leaky pipes, underground storage tank spills, or intentional deposits at waste dump sites [43, 73]. Both Pharmaceutical and Personal Care Products and pesticides enter the food chain through absorption into the food chains either by plants, aquatic organisms, or animals. These residual pesticides and their metabolites, or degradation intermediates could remain in plants, or in the soil eventually becoming a source of contamination for THMs [29].

Organochlorines stimulate the central nervous system which could result in tremors, hyperexcitability, and seizures. Although organochlorine pesticides generally do not elicit immediate toxic effects compared to organophosphates or carbamates pesticides, they are extremely hazardous due to their environmental persistence and owing to their higher lipophilicity, they tend to accumulate in animals' tissue as they move through the food chain [43]. There have been worldwide reports of residual organochlorine pesticide and their degradation products detected in soil, plants and animals' tissues and human breast milk [55]. The foremost harmful effects linked to overexposure to organophosphates are symptoms of the nervous system, such as paresthesia, discoordination, dizziness, headache, convulsions, or tremor. Organophosphates inhibit acetylcholinesterase resulting in the accumulation of acetylcholine in the nerve tissue and at the effector's organ, and culminating in the sustained stimulation of cholinergic synapses. Exposure to organophosphate results has also been associated with delayed neuropathy [3, 70]. The European Pharmacopeia and United States Pharmacopoeia acceptable limits for some common pesticides are summarized in Table 2.

3.2.2 Industrial Release

Xenobiotics such as toxic chemical substances may be discharged during a production process or as a final product. They may be released into the environment intentionally or accidentally, from automobile or industrial emissions which may cause widespread contamination of the ecosystem. Gas emissions associated with the operation of automobile and coal-fired power generating stations release toxic chemicals into the environment which can impact human health. The acid gases and greenhouse gases emitted during the combustion of coal contribute substantially to acid rain and have been linked with global warming [74–77]. The generation of

Table 2 Examples of some common pesticides and their residual limits in Medicinal Plants [55]

Substances	Ph. Eur. And USP
Dichlorodiphenyltrichloroethane (DDT)	1.0
Malathion	1.0
Diazinon	0.5
Parathion	0.5
Alachlor	0.02
Aldrin and dieldrin	0.05
Dichlorvos	1.0
Dithiocarbamate	2.0
Fonofos	0.05
Chlordane	0.05
Hexachlorocyclohexane	0.3

Ph. Eur. And USP (European Pharmacopeia and United State Pharmacopeia)

particulate matter and such gases as sulfur dioxide and nitrous oxides is associated with coal-fired power plants employed in electrical generation [78]. These substances may combine through chemical reactions to form fine particles in the atmosphere [78]. The reactive chemicals may spread over thousands of kilometers from the source of emission and result in the widespread distribution of xenobiotics. Besides the environmental harm orchestrated by greenhouse gases, acid rain, and other emissions, the contaminated air emitted from coal-powered electricity generating stations harbors a significant level of toxic compounds that negatively impact on both plants and human health [78, 79].

Medicinal plants are easily contaminated through absorption of heavy metals released into the water, soil, and air. Mostly, the soil is contaminated with toxic metals through atmospheric deposition from point sources such as an array of industrial processes, rainfall, atmospheric dust, and the application of plant protection agents [78]. Consumption of heavy metal-contaminated herbal drugs allows the entrance of the toxicants accumulated in herbs into the human body which can upset the normal functions of various organs in the body as earlier discussed. Among the heavy metals widely studied, Pb, As Hg, and Cd are very toxic and mutagenic even at minute concentrations. Instances abound where malformation of organs, physiological abnormalities, and ill health in humans have been traced to heavy metals toxicity have been reported [3, 20, 49, 80]. Besides humans, animals and plants also suffer upon exposure to toxic levels of heavy metals.

3.2.3 Wastewater and Irrigation

Contaminant constituents and concentrations in wastewater depend on the process producing the effluents and the technology employed in their treatment [43]. In developing countries, wastewater has been reportedly used for irrigation purposes in agriculture, especially in farmlands located within proximity of cities where they are generated. The practice of recycling wastewater benefits agripreneurs who harness the abundant wastewater loaded with organic matter cheaply serving dual purposes, namely irrigation and as organic fertilizers [81]. However, this practice exposes the plants to trace elements such as heavy metals and organic contaminants notably

POPs and PFAS, which abound in wastewater as well as represent a source of harmful germs, pharmaceuticals, and personal care products which are potentially toxic to plants [82, 83]. Toxic elements present in wastewater can pollute water supplies such as surface waters from rivers, streams, and impact agricultural soils, the environment, and humans either directly or through the food chain. The crops and medicinal plants become exposed to contaminants and may accumulate unwanted quantities of potentially toxic elements. Consumption of plants irrigated with untreated wastewater poses a high risk for human health due to the potential exposure to pathogens, and uptake and bioaccumulation of potentially toxic chemicals in edible parts of the plants [43]. Increased levels of heavy metal accumulation in plants have been reported from areas with a protracted history of growing on untreated and/or treated wastewater, previous dumpsites as well as plants growing along heavy traffic ways [3, 78].

3.2.4 Wastes Disposal

Agricultural and industrial wastes must be collected and managed in an environmentally safe manner. Poor waste management represents a potential route for xenobiotics entering the environment. For example, non-biodegradable irrigation tubing, mulching films, small tunnel films, and protective fleeces used in agricultural farms need extra care in their post-use management to ensure they are not left behind on site, thereby causing environmental pollution. Polystyrene seedling trays must be collected and removed from the fields after planting season [43]. In the event of poor waste management, the possibility of them being dumped indiscriminately such as in the open countryside, or disposal in open space is high which must be minimized. The wastes may subsequently be burnt in the open space to reduce volume. Toxic emissions and partially combusted particles containing contaminants such as the polychlorinated dibenzo-para-dioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) generated from such uncontrolled fire can then pollute agricultural soils and bioaccumulate in the food chain at both short and long-range [43].

3.2.5 Herbal Contamination by Adulterants

Adulteration of herbal preparations could be regarded as the deliberate or unintended introduction of other materials possessing different chemical properties hence inferior or differing therapeutic effects other than the original material [1]. The challenge of herbal medicinal products adulteration [35, 84] and associated cases of adverse drug reactions [85, 86] has become a problem with global spread [87]. Of 5957 herbal products surveyed using DNA-based methods, Ichim [87] reported the continental prevalence of herbal products adulteration was in the descending order of 79%, 67%, 47%, 33%, 27%, and 23% for Australia, South America, Europe, North America, Africa, and Asia, respectively. The Federal Drug Agency (FDA) of the US Tainted Supplements Report covering between 2007 and 2012 mentioned 332 dietary supplement products were adulterated; 95% of which were classified as sexual performance enhancers [84]. Sexual performance-enhancing products are commonly linked with contamination. For instance, these products are reported to contain synthetic phosphodiesterase type-5 (PDE-5) such as tadalafil, sildenafil, and vardenafil. These have up to 50 analogs with few structural modifications capable of eliciting similar pharmacological properties as the original products [88, 89]. Their contaminating presence raises questions, about whether the acclaimed therapeutic effects of such products could be attributed to the constituent botanicals or the contaminants. Similarly, Skalicka-Wozniak et al. [6] opined the associated adulterants expose consumers to adverse side effects, other than the desired pleasure outcomes. Herbal products for slimming purposes are another group of blockbusters owing to the global distribution of obesity. Often, marketed products for slimming down are commonly contaminated with sibutramine hydrochloride monohydrate (an anti-obesity drug that functions through the inhibition of serotonergic and noradrenergic reuptake) with its unapproved analogs [6]. Another study in Brazil reported a similar trend of sibutramine contamination from 106 sampled herbal preparations [90]. The Dutch national pharmacovigilance center Lareb reported about 15% of total reported serious adverse drug reactions traceable to adulterating contaminants. The authors [86] reviewed twenty-six herbal medicinal preparations and reported the presence of adulterants such as pollens, rodents, dust, insects, fungi, microbes, parasites, toxins, mold, pesticides prescription drugs and/or toxic heavy metals. These contaminants and adulterants are associated with severe clinical conditions such as multi-organ failure, metabolic acidosis, renal or liver failure, and perinatal stroke, among others [86]. Sadly, other contamination may be deliberately caused by vendors to increase the commercial value of their herbal products. Some of the deliberate means achieving such goals include substitution with subordinate commercial varieties, use of artificially manufactured substitutes, replacement with expired drugs, incorporation of worthless heavy materials of similar color or looks, introduction of inferior drugs [1].

3.2.6 Naturally Occurring Xenobiotics in Plants Used for Herbal Preparations

We have explored anthropogenic activities which lead to environmental pollution and other natural factors, which culminate in the pollution of plants and hence herbal medicine preparations sourced from such contaminated plants. However, there is another dimension to herbal products contamination. These could be associated with natural processes of the plants or associated plants in the field. The plant families of *Fabaceae, Boraginaceae*, and *Asteraceae*, produce pyrrolizidine alkaloids (PAs) as a chemical means of self-defense mechanism against herbivores [37]. While growing on the field, PAs were shown to be transferred from a producer *Senecio jacobaea* to acceptor plants grown within the vicinity of the producer, hence indicating a situation of producer-acceptor exchange hence cross-contamination of other plants with PAs, in a manner previously unknown, but thought to occur through the roots of the producer plants thereby contaminating surrounding soils [91]. The presence of PAs in plants other than producing plants could have far-reaching consequences on consumers of such plants derived products. The PAs have been detected in herbal preparations or formulations such as medicinal teas, phytopharmaceutical formulations, or other plants-based drug products [37] which imparts negatively on the medicinal value of the contaminated botanicals. The presence of weeds has been associated with the development of pyrrolizidine alkaloids (PAs) which has become a major source of contamination and have been discussed among health authorities for several years, culminating in the establishment of limiting values for PA content in herbal preparations [38]. They elicit toxic effects with the lungs being the primary target organ as the site of metabolic transformation [92]. PAs-induced toxicity does not spare the liver and other tissues of humans and livestock [92]. This class of natural xenobiotics has become important in quality control since their composition is affected by species of plant, location of growth, age of the plant with content getting to its peak preceding the flowering stage or early bud [93]. Such phenomenon poses constraints on the path of harmonizing the active ingredients content of herbal preparations.

3.3 Impact of Transportation of Xenobiotics on the Environmental Distribution of Pollutants

Transportation of xenobiotics is facilitated by both abiotic and biotic media. Among the two, abiotic processes hold a greater sway on the environmental distribution of pollutants. This entails the displacement of contaminants present in water, air, as particulate matter and transported by wind, or by the action of water, or soil solution, or even soil masses [94]. Once introduced into the environment, part of the xenobiotics (e.g., pesticide) get adsorbed to soil debris, and yet others become bound with the liquid and/or vapor phases. The extent to which a potentially toxic chemical is distributed between the liquid, adsorbed, and vapor phases greatly influences its subsequent distribution in the environment. Because xenobiotics may exist in all three phases, several transport routes influence their environmental distribution [95]. Potentially toxic chemicals such as agrochemicals applied on the surface of soil may degrade in situ or be transported from the target area through processes such as leaching into groundwater, runoff into nearby streams, and/or volatilization into the atmosphere.

3.3.1 Winds

Pollutants present in or adsorbed to soil can be transported around and offsite as aerosols or particles blown by the winds. Winds may transport only small particles, except in rare occasions where nonselective particles as much as a grain size can be easily transported as observed during hurricanes or cyclones. Thus, wind facilitates the movement and dispersion of xenobiotics to distant sites far away from point sources [94]. Wind transportation of chemicals – persistent organic pollutants, for instance – could be either long-range or short-range. Long-range transport potential (LRTP) for persistent organic pollutants (POPs) – most of which are xenobiotics – is determined by the strength of the wind, and weaker turbulence [96]. Thus, at higher atmospheric levels, xenobiotics could be transported over a thousand kilometers. Several factors are significant in facilitating air movement especially in long-range atmospheric transport (LRAT) involving persistent organic pollutants (POPs). This LRAT is reportedly responsible for the detection of POPs in extreme environments.

Tibetan Plateau in China is the largest and highest plateau on earth, a location which might be thought to be free of POPs. However, Wang et al. [97] reported the presence of a wide range of POPs on Tabetan Plateau in quantities that far exceeded those measured at other mountainous areas. Predominant POPs were identified as dichlorodiphenyltrichloroethane (DDT) and hexachlorocyclohexane (HCH) besides recently emerging compounds including polyfluoroalkyl substances and hexabromocyclododecanes, which have been widely distributed in fauna on the plateau [97]. They attributed the POPs' presence on the plateau to the LRAT impacts of The Indian Monsoon, East Asian Monsoon, and Westerly winds with polluting sources identified as being from the surrounding counties. Particulate matter (PM) size is instrumental in the transportation of POPs. Odabasi et al. [98] investigated particulate matter distribution in air from an industrial and urban settlement in Izmir, Turkey [98]. They reported proximity to the source of emission heightens the air content of POPs and holds the prospects of further contributing to the potential toxicity to surrounding plants when employed in herbal medicinal applications. Size distribution of particulate matter shows preferential deposition (>50%) in the fine particulate matter ($d_p < 2.5$ μm) because fine particles have higher sorption capacity than coarse particles (2.5 μm $< d_p <$ 10 μm) due to the relatively higher organic content component of fine PM compared to the coarse PM [98]. Other factors such as temperature and the octanol-air partition coefficient (K_{OA}) of POPs increase fine PM composition content and POPs composition, while increasing temperature decreases fine PM with significant correlations for up to 51% of studied compounds [98]. Other factors linked with LRAT are increasing height associated with wind speed, temperature changes, and reduction in decaying effects owing to surface friction [96].

3.3.2 Surface Runoff

Chemicals in surface runoff occur by mechanisms involving the erosion of sediment with adsorbed chemicals and the dissolution of chemicals into the runoff water [95]. Erosion of solid soil particles along with adsorbed xenobiotics occur through the independent or combined action of air, water, and temperature. It is facilitated by increase in the exposed surface area of the soil. In areas with a steep gradient, mass-wasting processes such as creep, slides, rock flows, debris flows, rockfalls, slumps, and block glides of the eroded materials are observed due to the influence of gravitational force. Environmental distribution of pollutants is also possible via transport in water in the form of particulate matter or in dissolved form; in ground or surface waters [94, 95]. In the case of surface waters, soil fragments are introduced into water bodies and flocculate as particles downstream by sliding, rolling, and saltation and are deposited further downstream. The rate or distance of flow depends largely on turbulence, flow velocity, grain size, shape, and density.

3.3.3 Leaching into Groundwater

Xenobiotics also frequently pollute groundwater by the process of leaching. Leaching is a process by which contaminants are freed from the solid phase into the aqueous phase orchestrated by the dissolution and desorption from their previously supported phases. Leaching of pollutants into groundwater is a vital process since it is closely linked with most pollutants of eminent environmental concern. The dissolved transport in waters allows pollutants to easily migrate to other sites or environmental compartments far from the source [94, 95].

3.3.4 Volatilization

The process of volatilization entails the release of a chemical (contaminant) from a solid or a liquid medium into the atmosphere or into the gaseous phase. Once in the atmosphere, potentially toxic xenobiotics may undergo degradation or become deposited in nontargeted areas through wet or dry deposition [99, 100]. Often, part of the chemicals volatilized into the atmosphere are transported and subsequently deposited in rivers, streams, and other important water bodies [95, 101, 102].

3.3.5 Drifts

Spray drifts represent another means of migration of xenobiotics into distant part of the environment away from source points. For instance, pesticide emissions can occur as spray drift in concentrated droplets or as pesticides attached to dust particles [103]. Xenobiotics spread from drift and volatilization can be transported through the atmosphere to forested areas and deposited directly into streams via tree wash-off.

Toxic elements and compounds emitted from industrial plants and the operation of automobile and coal-fired power stations release toxic chemicals into the environment.

Taken together, transportation of xenobiotics contributes greatly to the wide-spread distribution of xenobiotics and consequently results in risk to agricultural process located even far away from the source point.

4 Universal Variations in Botanicals: Impact on Quality Control of Herbal Preparations

The therapeutic impacts of botanicals are ascribed to the phytochemical variety, content, and composition present in the plant. Thus, fresh leaves tend to present better therapeutic effects and hence most employed in traditional medical practices. However, the presence of phytochemicals in plants varies with differences in environment where it is grown, climate, age of the plant/plant part, composition, soil components, and geographical region where the plant is grown [104]. Since these factors vary from one plant to another, and soil composition and components vary largely with anthropogenic activities; these factors as expected would contribute largely to the problems of standardization. Moreover, there are preferential seasons for harvesting different plant parts for use in herbal preparations. For instance, roots and rhizomes are better collected at the end of vegetation period, leaves and herbs at bloom, bark in the spring, flowers preferably at anthesis or shortly after opening, while fruits and seeds are collected after maturity or ripe [105]. During herbal preparations, aqueous formulations are administered.

The water used in preparing the solutions may be contaminated, as they tend not be a universally similar quality of water to use from wherever the formulation is being made. However, one of the pressing public health concerns of the twenty-first century remains clean water for human use [106]. Nigeria is a prime example of the situation in the global south. While water resources are abundant in most parts of the country [107, 108] especially during rainy seasons which occur between April and November in most parts of the country; drinking water remains an out-of-reach commodity for the majority. Some of the key sources of contamination of drinking water resources in Nigeria arise from such causes as agricultural activities, abattoir effluents, industrial effluents, leachates, oil spill, scrap yards, and municipal waste [109] thereby contaminating even drinking water resources. For instance, only about 11% of Nigerians have access to pipe borne water, and only 4% premises are supplied with pipe-borne water [110]. The same source noted massive contamination of drinking water with *E. coli* at 68% and 70% at the source and point of consumption, respectively. The presence of pollutants in water implies the polluting contaminants are added into the herbal preparation, further contributing to the problem of loss of standardization.

5 Improvements in Quality Control Strategies: A Panacea for Herbal Products Contamination

Different kinds of contaminants have been associated with herbal preparations. Commonly mentioned ones include microorganisms, fungi and associated mycotoxins, heavy metals and other elemental impurities, trace organics such as pesticide residues, pyrrolizidine alkaloids through weeds [8, 11, 38, 111]. As the kinds of contaminants vary widely, so also their sources. Therefore, an effective quality control strategy will involve an all-encompassing approach, covering the different kinds of contaminants identified. All these are applicable in the global south, hence the need to address all of them. The entire discussion would be beyond the scope of a single book chapter. The kinds of approaches employed would include chemical, biological, microscopic, physical, and biological evaluations [10]. Several analytical techniques are being engaged in checking the integrity of herbal preparations. The ever-increasing analytical sensitivity associated with high throughput DNA sequencing enables its use in determining untargeted contaminants and simultaneous multi-taxa identification [87] has presented special prospects in improving the quality of herbal preparations. While chemical analytical techniques can identify and quantify these contaminants and toxins, they usually suffer a limitation in their ability to the source of the contaminant, a gap DNA barcoding leverages upon [112, 113]. Besides, using amplicon metabarcoding, labeled ingredients are verified and substituted, adulterated, and added species are identified, thus further proving to be an indispensable tool in quality control assessment. Several other techniques have been applied in the detection of contaminants in herbal preparations. Elemental analysis has employed the techniques of graphite furnace atomic absorption, flame absorption spectroscopy, cold vapor atomic absorption [111], and inductively coupled plasma emission optical emission spectroscopy, ICP-OES. The hyphenated analytical techniques of Gas Chromatography-Mass Spectrometry (GC-MS), High-Performance Liquid Chromatography-Mass Spectrometry (HPLC-MS), Liquid Chromatography-Nuclear Magnetic Resonance (LC-NMR), High-Performance Thin Layer Chromatography-Mass Spectrometry (HPTLC-MS) [114], Fourier transform infrared spectroscopy (FTIR) as well as simpler analytical techniques such as column chromatography [5] have particularly played key roles in the chemical evaluation of HMPs. Thus, the applications of these techniques in regulatory laboratories, manufacturing companies, academic research spaces can tremendously ensure the appropriate quality of herbal products are available for sales and consumption. Though the costs be large, there is no short cut to take to ensure health and safety of the hundreds of millions of inhabitants found in the national boundaries of the global south communities.

As often observed, the global south is composed of evolving economies lacking the financial capacity to implement the array of analytical techniques outlined above. While this is a disadvantage, it is also a huge advantage to the global community in disguise. Here in this region lies large numbers of unexploited natural products of promising immense therapeutic importance. Collaborations between academics, governments, and Civil Society Organizations (CSOs) will bridge this gap and release the avalanche of untapped resources for the benefit of humanity.

6 Summary

Xenobiotics are commonly identified in herbal medicinal products across the globe. As contaminants, they vary in composition and content. This variation is attributable to environmental factors, geographical location where the plant was sourced, age of the plant and even intraspecies variations are reported, among several other factors. Some of the major identified contaminants may be classified under different classes viz.: pharmaceuticals, pesticides (agrochemicals), other industrial products/heavy metals, nuclear wastes, illicit drugs, and personal care products. These contaminants could be contained in industrial discharges, untreated or partially treated wastewater effluents, and irrigation water, solid and e-waste disposals, among others. The contaminants could be transported from point release to further distances and distributed to other locations by winds, surface run-off, leaching, volatilization, and drifts. Different analytical techniques have been employed in identifying and sometimes quantifying these contaminants. Often employed analytical techniques are inductively coupled plasma emission optical emission spectroscopy, ICP-OES, HPLC, HPLC-MS, LC-MS, GC-MS, capillary electrophoresis, and high-throughput DNA-based sequencing techniques. Naturally occurring xenobiotics are another class of compounds, such as pyrrolizidine alkaloids, that have been identified in herbal preparations with established fatalities. Although the universal composition of botanicals varies largely, with the application of stringent quality control procedures, the problem of xenobiotics contamination can be minimized. This will instill efficacy hence confidence in such products, boost economic activities around

the trade in herbal products, lessen public health burden, and achieve the desired goal of using traditional medicinal products. Most importantly, it will cater for the rural dwellers of the global south, whose readily available medical relief products are the traditional herbal preparations, hence increasing economic viability and general well-being.

7 Conclusion

Herbal medicinal products (HMPs) are a viable means of global trade and beneficial in sustaining fragile health care systems around the globe, especially in the developing global south. Plagued by contaminants, the good intent for their consumption may become ill-fated, owing to the presence of contaminants. Contaminants which are of different kind and arises from different sources such as microbial, elemental, pesticides' residues, and natural sources pose serious threats resulting in adverse drug side effects and sometimes death. These must be controlled through carefully crafted, and economically feasible quality control measures, spearheaded by governmental regulatory bodies, researched upon and regularly checked by the academic researchers. CSOs may lead the awareness campaigns while ensuring appropriate information is disseminated to all stakeholders in the value chain of HMPs. The global south must form collaborations with developed economies to identify and monitor for contaminants of public concern as a measure toward monitoring for the control of their presence in herbal products.

8 Recommendations

- Following national surveillance over a 30-year period, van Hunsel et al. [85] concluded that pharmacovigilance of herbal products in necessary to guarantee citizens' safety following consumption. While the Dutch national pharmacovigilance lab and database at Lareb offers such services, in many countries of the global south such as Nigeria, a detailed analysis of herbal medicinal products may be lacking, hence exposing the citizens to further medical complications.
- Comprehensive value chain overhaul of the HMPs is necessary, especially for registered products. Since these are often sourced from botanicals, comprehensive soil analysis and air monitoring should be periodically carried out to establish best-growing conditions for cultivated botanicals targeted for HMPs production. The siting of such farms should also consider environmental factors such as topography, presence of point source pollution releases.
- Registration of HMPs with statutory regulatory bodies should be carried out to ensure standardization and quality control measures are achieved and maintained. This will enable the producing companies to be accountable to the governments and consumers for the products they sell. This is challenging in the global south, where most herbal preparations come from local traditional medical practitioners. On the flip side, such attend to fewer persons hence limiting the scope of

consumers and consequently the extent of public health implications that may be recorded. Even though small, the impacts must still be minimized through locally sustainable approaches,

- Local dwellers should be enlightened on the side effects and potential toxicities associated with herbal medicinal products, to minimize wanton consumption and limit it to only in cases where necessary.
- Traditional medical practitioners should be enlightened on the best practices to employ in harvesting, preparations, storage, and administration of botanicals and resultant herbal preparations to minimize the associated adverse effects. This could be part of a national or regional quality control approach in ensuring public safety and improving public health, as was also recommended previously [11].
- Registered HMPs must be monitored to ensure adherence to production processes just like conventional pharmaceuticals production processes are under the radar of regulatory agencies. Also, labels must be checked to ensure conformity with actual ingredients content.
- Furthermore, community advocacy by learned persons, institutions, concerned civil society organizations, national bodies associated with HMPs and traditional medical practices should be done. This will enlighten stakeholders and through these efforts improve public health and safety while maximizing the anticipated health, economic, and traditional gains associated with the herbal products.
- Regulatory agencies must step up their activities to ensure the safety of the populace. This is beneficial especially for licensed products. This should be surveyed regularly to ensure consistency with labels and uniformity of constituents. This is important since the active ingredient content of botanicals may vary with season, site of cultivation, and several other factors that are highly variable.

Abstract

Herbal remedies have been developed and used since the dawn of human civilization. Herbal medicines preponderantly deal with the medicinal application of a broad spectrum of plant regimes for health management and disease prevention. Wider varieties of algae, fungus, and lichen exudates have also been considered for herbal medicine using traditional methods such as infusion, decoction, maceration, distillation, expression, fractionation, and purification. However, conventional channels are insufficiently successful to generate significant demand for industrial-scale manufacture of herbal medicines. Systems synthetic biology and metabolic engineering have proved important in boosting productivity and cutting costs in the production of herbal drugs in this area. Additionally, there are regulatory and bioethical problems for health management and illness prevention at the current state of the art that make it difficult to mass-produce herbal medications. Based on this current scenario, current chapter deals with general outline on herbal medicines; its impact on health management and disease prevention; impact of system synthetic biology and metabolic engineering to accelerate herbal medicine development; and brief outline on regulatory-bioethical aspects upon usage of herbal medicine for health management and disease control.

WHO	World Health Organization

1 Introduction

Herbal medicine is the oldest and traditional way of pharmaceutical industry. In the arena of medical products, it has been crucial. Natural products always have come from plant roots, flowers, fruits, seeds, leaves, bark, fruits peels, even entire plant, etc. They consist therapeutic activities and primitive human world, and most of the old healthcare have depended on natural ingredients of medicine rather than synthetic medicine. In India, the forest produces over 90% of the herbs and medicinal plants. Between 1950 and 1970, almost 100 distinct plant-based medications were released to the American market, including the higher plant-derived medicines vincristine, deserpidine, and rescinnamine [1]. When chemical analysis first became possible in the early nineteenth century, scientists started to extract and alter the active components from plants. Later, scientists started creating their own versions of plant chemicals, which led to a gradual fall in the usage of herbal remedies in favor of pharmaceuticals. Recent demands for drug production and quantity have increased due to increased resistance to pathogenic microorganisms, and traditional methods of the production of natural medicines are unable to meet these demands. Sustainability of production and green development has become increasingly prominent demands. Life science has a modern interrelated part synthetic biology that has an impact on traditional metabolic engineering and concept of systems biology [2].

2 General Outline and Classification of Herbal Medicine

Herbal medicine, according to World Health Organisation (WHO) guidelines, encompasses herbs, herbal materials, active components with therapeutic actions, and even negative consequences. Herbs are the roots, flowers, leaves, bark, fruit peel, seeds, gums, and so on. Herbs are classified into distinct categories based on their applications and activities. There are different types of herbs as they have different uses and activities. Herbal materials refer to some extra processes on herbs to get a typical extract. These extra processes are may be boiling, blending, grinding, and even by soaking the herbs. By these processes, extract product may be fruit juice, powder of seeds, peels, and barks, even dry petals of flowers, leaves, etc. Active ingredients mean why the herbs are active or effective? Herbs must include some element that allows them to function as active or effective products, which can be any enzyme, vitamin, antioxidant, antibacterial, therapeutic activity, and so on. The entire herbal remedy may be regarded as an active ingredient when it is impossible to identify the active component. Successfully preventing, diagnosing, and treating bodily and mental illness is referred to as therapeutic action. Side effects are any unintended consequences of using a drug at its recommended dosage for treating humans [3]. "Preparations manufactured industrially consisting of active ingredient(s) that are/are purely and naturally original, not chemically altered plant substance(s), and are/are responsible for the overall therapeutic effect of the product," is another description of a herbal medicine. Consumers are turning to plant-derived preparations because they believe that since HMs are natural products, they are safe – if not safer – than conventionalized pharmaceuticals [4]. The quality of a natural product is also determined by user feedback. Categorization of a full herbal product occurs in a variety of methods.

2.1 Classification of Herbal Remedies According to Their Uses

The majority of culinary herbs are spices that are used to flavor food and have been utilized in traditional medicine for thousands of years due to their presumed and known health benefits. For instance, mint, curry leaves, fennel seeds, fenugreek seeds, black pepper, turmeric, ginger, garlic, parsley, cinnamon, clove, cardamoms, honey, etc. Ornamental herbs mean they are used for decoration and fragrance of surrounding air because of their colorful flowers, leaves, and good smell. Some of these are lavender, rose petals, myrrh lemon leaves, *Clitoria ternatea* (common name bluebellvine), rosemary, chives, oregano, aloe vera, etc. Medicinal herbs consist any of one protectiveness such as antimicrobial, antioxidant activities, etc., by which they can prevent disease by internally and externally. Most of the medicinal herbs are common as culinary herbs such as mint, fennel seeds, fenugreek seeds, neem, turmeric, ginger, garlic, cinnamon, clove, cardamom, honey, curry leaves, etc. Besides more herbs are vasaka, hibiscus leaves, green chiretta, *Hygrophila auriculata* (common name kokilaksha), *Centella asiatica* (thankuni leaves), aloe vera, Indian snakeroot, *Bacopa monnieri* (common name water hyssop), etc.

2.2 Classification of Herbal Medicine Based on the Period of Life

Annual herbs, such as anise, basil, borage, parsley, saffron, and others, blossom for only one season and then die. Biennial herbs are plants which live more than one or up to two seasons like caraway seeds, prime rose, etc. Perennial herbs grow for more than two seasons. Some of these are aloe vera, lavender, bay leaves, rosemary, lemon balm, etc.

2.3 Classification of Herbal Medicine Based on the Properties

Aromatic herb, as the name suggests, gives a pleasant odor, for example, lavender, rose petals, or a strong odor to reduce bad odor. For example, ginger, myrrh lemon leaves, clove, etc. Bitter herbs contain phenols, phenolic glycoside, alkaloids, and saponins. They commonly act as blood purifier like neem; besides, they contain anticatarrhal, antipyretic, vermifuge activities, e.g., aloe vera, cascara, pumpkin, etc. Diuretic herbs cause the body to lose fluid through the urine system. Asparagus, blessed thistle, corn silk, and parsley are a few foods that are healthy for the liver, kidneys, and circulatory system. Polysaccharides found in mucilaginous herbs give them a slick, mild flavor that tastes pleasant when consumed with water. The majority of mucilages, including glucomannan from konjac root, Irish moss, althea, aloe, burdock, and fenugreek, absorb toxins from the stool instead of being broken down by the human digestive system. Herbs that are nutritious impart their nutrition to the consumer. They are primarily available as food products, but they also have some medical properties like fiber, mucilage, and diuretic activity. As necessary nourishment, they also include carbohydrates, proteins, healthy fats, vitamins, and minerals. For example, apple, asparagus, banana, barley grass, bilberry, broccoli, cabbage, carrot, grapefruit, hibiscus, lemon, onions, orange, papaya, pineapple, wheat germ, etc. [3].

2.4 Classification of Herbal Medicine Based on Extraction Processes

Some herbs are used after drying and grinding, like orange peel, fenugreek seeds, and hibiscus leaves. Some herbs are used after soaking, like curry leaves, fennel, ginger, mint, etc. Some herbs are used after blending, like vasaka, thankuni leaves, kokilaksha leaves, Indian snakeroot, etc. Two essential criteria or qualities that must be taken into consideration for an HM to be assessed and evaluated under the proper registration procedure are the presentation of the product and the purpose for which it is provided. Dietary supplements are only permitted in oral preparations under the USA regulatory authorities; all other preparation types fall under the category of botanical pharmaceuticals, which have the toughest registration requirements.

3 Traditional and Current Methods for Developing Herbal Medicines

As ancient as human civilization itself is the history of herbal medicine. Herbal remedies refer to a natural substance that must also evolve together with our lifestyle. Without growth characteristics, purity, efficacy, and manufacturing speed, herbal medication development is useless. Each phase of technique extraction and production is accountable. It is also necessary to investigate how they affect the body. A large portion of the Indian population is depending on the Indian system of Medicine – Ayurveda, an ancient science of lives till now [5]. But natural medicine has been excluded by regular uses of synthetic drugs due to disqualification of traditional production of natural medicine. This use of synthetic medicine acts as a threat to the environment and biodiversity as well. In order to acquire adequate enhancing capacity, it is essential to promote and integrate herbal medicines into primary healthcare. This should be done in a sustainable manner. It could lead to the development of new drugs, increased access to healthcare, the preservation of forest resources, and assistance in closing socioeconomic gaps and meet the Sustainable Development Goal (SDG) as well as the World Health Organizations' (WHO) promotion of herbal medicines. Several factors can influence traditional methods like (1) study of effectiveness of plant remedies, (2) an unhappiness with the effects of synthetic medications and a consumer perception that herbal treatment is superior, (3) the high cost and side effects of the majority of contemporary medications, (4) patients' beliefs that their doctors have not accurately diagnosed the issues, leading them to believe that herbal therapies are a superior alternative, and finally (5) herbal remedies need some development approaches that can influence their efficacy, quality, safety and budget friendly cost and conference to move towards herbal remedies like increasing quality of extraction of flavors or chemicals from plants by soaking in water, called infusion, and extraction of water-soluble products by boiling plant, roots, etc. A synthetic cell is transformed into a suspension of intact cell to get a better quality of medicine. There are further quality control procedures, such as distillation, which is used to distil all types of liquid goods, fractionation, which is used to separate subcellular components, and purification, which is used to check purity, among others. Before studying the approaches of development of herbal medicine, it requires to have proper knowledge on trends for traditional method or natural method of herbal medicine developments.

3.1 Conventional System's Effects on Basic Healthcare

Herbal medicine has benefited greatly from India's reputable and well-coordinated healthcare system. Before the growth and dissemination of contemporary science, traditional systems of herbal treatment were the reasonable and essential component of several cultures. Additionally, it suggests a number of efficient medications for the management of hepatic problems [26, 28].

3.2 Efficiency of Traditional System

The roots, leaves, bark, and other plant parts are used to make herbal products. They undoubtedly contain a variety of biologically and chemically active substances, as described in the point that follows. Plants are deemed medicinal if they exhibit pharmacological properties with potential therapeutic use. As a result of millennia of trial and error, these practices are typically well-known, but they need to be carefully explored if we want to develop fresh treatments that meet the demands of modern therapy.

3.3 The Objectives of This Field's Research

The active components of medicinal plants must be identified, and the safety, efficacy, and ongoing action of the extracts must be confirmed. It is possible to synthesize, structurally modify, or simply extract these active components with greater efficiency by the isolation of these substances and the characterization of their structure. Research on medicinal plants must follow a strict protocol. Simple technical mistakes frequently diminish the value of studies on natural goods. By ensuring the process of raw material cultivation, identification, recognition, collection, and preservation, a natural medication will become a well-liked herbal medicine among consumers. To ensure that the desired outcome of the products is achieved, it is necessary to process, store, and use raw materials and finished products in accordance with current Good Manufacturing Practices (cGMP). To hold this eco-friendly management, it must require development in each portion. Some strategies or approaches must be followed by this management. Manufacturing and formulation-based strategies: Making a safe and effective herbal medication requires several important procedures, including ensuring the correct number of recipients and revalidating the composition. Utilizing contemporary technologies and creating patient-centric innovative herbal formulations will increase consumer acceptance of the medication for both treatable and untreatable conditions. The right dosage for the right disease is a crucial component of disease prevention. Therefore, randomize clinical trials in multicenter, multinational, and multicultural settings are an essential strategy for spreading herbal medicine around the world.

3.4 Host-Based Strategies

Drug resistance (DR), which can be either inherent or acquired, refers to the failure of a drug's capacity to effectively kill pathogens or inhibit their metabolism. For instance, *Staphylococcus aureus* and *Neisseria gonorrhoeae* almost have immunity to survive in benzyl penicillin. In addition to developing naturally, drug resistance is also unnecessarily accelerated by sloppy practices in drug supply and use. Most of the microorganisms that cause these disorders have a resistance to first-line medications that ranges from zero to approximately 100%. Drug inactivation or modification, target site modification, metabolic pathway modification, and decreased drug accumulation are the four primary mechanisms for DR. Race and poverty are socioeconomic characteristics that have an impact on pharmacological therapy accessibility and adherence. Racial variety, host-defense differences, genetic shift and drift, and other non-modifiable limiting factors are cited to support the safety and efficacy of herbal treatment. Therefore, trials that are multicenter, multicultural, and multiracial may help to solve the issue of spreading herbal medicine globally.

3.5 Consumer Satisfaction-Based Strategies

Natural ingredients are constantly used to make herbal medicines. However, they also have certain detrimental effects on the human body. Typically, consumers expect herbal medicines to be pure, effective, safe, and affordable. If these demands are fulfilled, then the herbal medicine will gain popularity. Adverse drug reactions (ADRs) of an each and every drug must be followed by repeatedly taking a single dose for a specific period. Therefore, it is crucial to prescribe herbal medicines to consumers after conducting thorough clinical research and gathering vast amounts of data.

3.6 Laboratory-Based Strategies

Evaluation of drug absorption, distribution, chemical changes in the body, effects and routes of drug metabolite excretion, biochemical and physiological effects of drugs on the body or on microorganisms or parasites inside or on the body, mechanisms of drug action, and the relationship between drug concentration and effects (pharmacodynamics) are all crucial factors in the development of natural medicine. Drug-drug interactions, drug-food interactions, drug-plant interactions, and even drug-enzyme interactions have been seen after a certain drug has been applied, such as the human body, any microorganism, or any plant. Carelessness, ignorance of the active ingredients in the relevant medications, or incorrect handling could all be contributing factors to these interactions. The proper personnel must be hired at the right time and location, a biosafety level must be established, standard containments must be used, and high-tech equipment for in-vivo and in-vitro investigations must be used in order to achieve the goal of herbal medicine globally [28].

3.7 Quality or Fertility or Maturity of Raw Material-Based Strategies

All of the previously described raw material-based tactics cannot be successful without the quality of herbal medicine, fertility, or maturity. We know that the natural medicine is produced from living organisms such as plants, microorganisms, and animals, but when a natural bioactive product is coming from plants, it needs to be mature and pure within plant cells. Therefore, the entire plant needs to be grown and mature properly, which is doubtlessly a time-dependent process; otherwise, researcher or collector will not be able to collect proper stage of bioactive component. In that instance, if natural products can be extracted from microorganisms, the method will be simpler and faster. A microbial cell may mature and produce bioactive chemicals thousands of times faster than a complete plant. The role of microorganisms in the natural medicine have been discussed in many articles. It is best to start by noting that the maritime environment has a great variety of ecosystems that are adapted to a wide range of environmental factors, including temperature, nutrient availability, and lit/unlit areas. So, in the marine ecosystem, most dominant are sponges, some fungi, then sea whips, sea fans, soft corals, tunicates, opisthobranch mollusks like nudibranchs, sea hares, echinoderms like starfish, sea cucumbers, and bryozoans like marine algae, including green algae, brown algae, red algae, golden algae, and diatoms, as well as marine bacteria are also involved in producing effective bioactive compounds.

From 1928, Alexander Fleming's discovery of lysis and inhibition of the growth of *Staphylococcus* on Petri dishes colonized by the penicillin from fungus *Penicillium rubens* (named at the time as *P. notatum*, and until recently as *P. chrysogenum*) which was isolated from the fungus *Penicillium notatum*, makes believe that microorganisms are a rich source of unique bioactive compounds [29, 30]. There are many fungi, which have the capability to produce antibacterial bioactive compounds like statins and mevastatin from *Penicillium citrinum*, lovastatin from *Aspergillus terreus*, strobilurins from *Strobilurus* species, and so on. Not only fungus, there are many *actinomycete* bacterial species those can produce antifungal, antitumor activity, and so on. Some bioactive components and producing microorganisms are mentioned in Table 1.

4 Health Effects of Herbal Medication

From the beginning of human civilization, herbal medicines have lot of uses to cure disease. All herbal medicines are typically derived from six main sources, including plants, animals, minerals/earth, man-made and semi-man-made materials, microorganisms, and recombinant DNA technologies [3]. There should be a focus on health rather than sickness, according to well-known herbal medicine systems such as traditional Chinese medicine and Ayurvedic medicine. About 100 years ago, natural herbs were the mainstay of human ailment treatment. Eighty percent of people globally, or around $60 billion yearly, rely on herbal medicines for some part of their basic healthcare, according to a recent estimate by the World Health Organization. According to estimates, 25% of current medications – including aspirin, artemisinin, ephedrine, and paclitaxel – are derived from plants that were originally used traditionally. The use of plant-based pharmaceuticals and dietary supplements has recently increased. Researchers in the fields of pharmacology, microbiology,

Table 1 Applications of various herbal remedies as well as the bioactive chemicals they contain and the microorganisms that produce such compounds

Brand name of medicine	Precursor bioactive compound	Producing microorganism	Applications	References
DAFLON 500	Flavonoids	*Annulohypoxylon elevatidiscus, Xylaria papulis BCRC 09F0222, Tricoderma* species	It has antibacterial, antifungal, antitumor, anti-inflammatory, and antiaging activities	[8]
Mevastatin	Compactin	*Penicillium compactum*	Helps to maintain cholesterol	[9]
Amoxil, Bactocil, Nacfil, etc.	Penicillin G	*Penicillium rubens*	Prevent bacteria from synthesizing peptidoglycan and used to treat throat infections, syphilis, meningitis, etc.	[10]
Pciltaxel (PTX)	Taxol	*Sorangium cellulosum*	It has antitumor and antifungal activities	[11]
Tygacil	Tigecycline	*Streptomyces aureofaciens*	It can effect on tetracycline resistance bacteria	[12]
Afinitor Disperz	Everolimus	*Streptomyces hygroscopicus*	It is an immunosuppressive agent	[13]
Invanz	Ertapenem	*Streptomyces cattleya*	It is also an antibacterial agent	[14, 15]
Elidel	Pimecrolimus	*Streptomyces hygroscopicus*	It is anti-inflammatory for skin disease	[16]
Myfortic, CellCept	Mycophenolic acid	*Penicillium stoloniferum*	Immunosuppressive agent in organ transplantation	[17]
Brostallicin	Distamycin A	*Streptomyces distallicus*	It has anticancer activity	[18]
Gilenya	Fingolimod	*Isaria sinclairii*	It can treat a very rare disease, multiple sclerosis	[19]
CellCept, Myfortic	Mycophenolic acid (MPA)	*Penicillium brevicompactum*	It has immunosuppressive activity	[20]

botany, and natural product chemistry are scouring the planet for phytochemicals and other potential drug "leads" that might be used to treat a variety of disorders. Some of the plants have been found to have antibacterial, antifungal, anticancer, antidiuretic, anti-inflammatory, and antidiabetic properties. Mental diseases are treated with plant-based medications. Among the most prevalent are skin disorders, cancer, diabetes, jaundice, hypertension, and tuberculosis [6].

In line with WHO, the current pharmacopoeia contains at least 7000 medical substances that are derived from plants. Significant changes in plant features have been linked to different soil types in several medicinal and aromatic plants.

Examples include morphine from the opium poppy, digoxin from foxglove, quinine from the bark of cinchona trees, and aspirin from willow bark. Herbs are high in nutrients since they are derived from plants in the same way. However, occasionally they have had unforeseen results. They could cause asthma, headaches, dizziness, agitation, dry mouth, seizures, exhaustion, tachycardia, nausea, vomiting, and diarrhea. They might also cause allergic reactions. There have also been reports of severe adverse effects. Kava-kava has been linked to cases of hepatotoxicity (liver damage), and the majority of herbal medicines have been linked to anaphylactic reactions that can be fatal [7]. Due to their hazardous chemical or heavy metal content or adverse drug interactions, even herbal remedies can induce kidney failure and liver damage in some users. Before releasing herbal medications into the market, the Therapeutic Goods Administration (TGA), according to Professor Roger Byard, should subject them to independent testing. Byard also suggested that when a product did not adhere to legal requirements, legal action should be explored. According to TGA statistics on complementary and alternative medicines from 2015 to 2016, there were even greater rates of quality issues, according to Dr. Ken Harvey, a medicinal drug policy specialist with Medreach. "Toxic side effects of herbal medicines used in traditional societies have typically not been reported, and this is often cited in favour of their safety," Byard added. Therefore, any substance considered a medicine, whether natural or not, can have both positive and negative impact on consumers. Some herbs and their positive and negative effects on human health are discussed in Table 2.

5 Impact of Herbal Medicine on Disease Prevention

It has long been known that plants have healing qualities. Indigenous societies have employed traditional herbal therapy to treat a wide range of illnesses for ages [43]. The potential of botanical agents for illness prevention can be found through historic uses of therapeutic plants. Due to the decreasing efficacy of some synthetic drugs and the rising contraindications to their use, the question of using natural drugs comes up [44]. The therapeutic efficacy of medicinal plants, particularly their antibacterial properties, is determined by secondary metabolites or compounds contained in the plants, such as tannins, terpenoids, alkaloids, and flavonoids [45]. Different medicinal plants can be used to prevent illnesses such chronic illnesses, metabolic syndrome, malaria, diarrhea, tuberculosis, asthma, and urinary tract infections.

5.1 Chronic Diseases

Numerous chronic diseases, including diabetes, cancer, cardiovascular disease, inflammatory bowel disease, and neurologic disorders, are on the rise as a result of considerable changes in human nutrition and lifestyle [44]. One of the most

Table 2 Different herbs, their active components, and their positive and negative effects on human health

Herbs	Texture of extracted product and extracted portion	Active ingredients	Positive impact	Negative impact	References
Azadirachta indica (neem)	Juice and oil from leaves and bark	Azadirachtin, nimbidin, nimbidol, ascorbic acid, quercetin, and polyphenolic flavonoids	Prevents diabetes, fungal and bacterial infections, and rashes It fights against tumor, cancer, etc. Even regulates apoptotic regulation	Taking neem seeds and bark by mouth is unsafe for child and during pregnancy It may be responsible for vomiting, diarrhea, etc.	[22]
Aloe barbadensis miller (aloe vera)	Gel from leaves	Vitamins A, C, E, and B12, folic acid, salicylic acid, enzymes, minerals, sugars, lignin, saponin, and amino acids	Lowers blood sugar and cholesterol Fights against acne, skin disease, dandruff, anal fissure, etc.	It can cause cramping, diarrhea, and imbalance of electrolyte in blood. It can disrupt other drugs (diabetes and heart disease)	[23, 24]
Mentha piperita L. (mint)	Liquid juice or oil from leaves and whole plant	Menthol, menthyl, acetate, menthone, rosmarinic acid, isomenthol, vitamins C and B6, iron, sodium, calcium, etc.	Peppermint fights against diarrhea, indigestion, cough, headache, migraines, menstrual cramp, chicken pox, etc. It reduces morning sickness, vomiting during pregnancy, even toxicity induced by arsenic, etc.	Heartburn, gallbladder, inflammation, sometimes liver damage is also caused by peppermint Menthol causes jaundice in new born babies, allergic reaction, etc.	[25]
Curcuma longa L. (turmeric)	Juice from raw roots and powder from dry roots	Main leader of the advantages of *Curcuma longa* is curcumin (yellow polyphenolic pigment) Curcumin consists of carbohydrates, protein, fat, and another important component is curcuminoid that contains curcumin, demethoxycurcumin (DMC), and bidemethoxycurcumin (BDMC)	It fights against diabetes, inflammation, cancer, bacterial and viral diseases, etc. It lowers joint pain and chances of heart disease. It helps to lose weight, promotes good sleep, prevents production of the melanin, etc.	After all goodness, it is responsible for a few negative effects such as dermatitis, allergies, digestive disorders (abdominal pain and diarrhea), synergistic effects, etc. Sometimes it acts as an inhibitory agent for other drugs and human sperm mortality to alter fertility	[26, 27]

Zingiber officinale (ginger)	Juice from underground stem	The major compounds are gingerol, shogaol, zingiberene, zingerone, terpene, vitamins C and B6, minerals, etc.	It reduces headache, cough, frequency of vomiting, and nausea significantly. In a little amount, this herb can recover muscle strength. Even it is useful regarding improving biochemical obesity indicator and weight loss	It has no such harmful effect, but among the adverse effect, gastronomical related symptoms. Sometimes it is responsible for causing diarrhea during heavy menstrual bleeding	[28, 29]
Allium sativum L. (garlic)	Juice from lower part of shoot system	Allicin is the sole active compound of *Allium sativum.* (allinase enzyme activate and produce allicin from alliin when chopped or crushed) Other important compounds are 1-propenyl thiosulfonate, (E,Z)-4,5,9-trihidodeca-1,6,11-triene 9-oxide (ajoene), and y-L-glutamyl-S-alkyl-L-cysteine. Steam distilled garlic oil consists of diallyl, allyl methyl, and dimethyl mono to hexasulfides	To recover from cardiovascular disease, garlic has significancy since ancient time. It has antitumor, antidiabetic, antimicrobial, antiprotozoal, antifungal, and antidiabetic effects. Even it succeeded to prevent chemical-induced hepatotoxicity	It increases the risk of bleeding, heartburn, and digestive problems Garlic contains a variety of sulfur compounds that may cause bad breath especially when eaten in large amount	[30]
Murraya koenigii (curry leaves)	Juice from leaves	It contains copper, fiber, phosphorus, carbohydrates, magnesium, vitamins A, C, and B6, some amino acids, etc.	It helps to lower cholesterol, maintain eye and liver health, treat damaged hair, lose weight, improve blood circulation (menstrual problems and gonorrhea), prevent or treat diabetes, anemia, treat dysentery, diarrhea, morning sickness, and nausea, even control other drugs' side effects, and also flush out toxins and body's fat content	It creates allergic reactions (rashes, itching, and swelling) It may cause stomach upset due to high fiber and low blood pressure	[31, 32]

(continued)

Table 2 (continued)

Herbs	Texture of extracted product and extracted portion	Active ingredients	Positive impact	Negative impact	References
Cinnamomum verum (cinnamon)	Powder from dry bark	Most important components are cinnamaldehyde and trans-cinnamaldehyde Besides, it contains sodium, potassium, vitamins C and B6, protein, iron, calcium, magnesium, etc.	It helps to low diabetes, cholesterol, heart disease, infection, allergies, tooth decay, etc. It is also used to treat HIV, cancer, Alzheimer's disease, and it is good for our intestine	It normally has no negative effects, but excessive use is bad for the lips and mouth, can induce allergic responses, can cause liver damage, disturb other medications, and is not appropriate to take as a treatment during pregnancy or post-pregnancy (breastfeeding)	[33]
Syzygium aromaticum (clove)	Powder from dry flower buds	Main bioactive compounds are eugenol, eugenyl acetate, and caryophyllene Besides, iron, calcium, sodium, magnesium, vitamins A and B6, etc., are present in this herb	It is good for diabetes, oral and dental problems, stomach upset problems such as vomiting, bloating, indigestion, diarrhea, etc. It acts as immunity booster, bone strength developer, etc.	It can cause severe side effects such as seizures, liver damage, and fluid imbalances. In the large amount, it is not safe for pregnant or breastfeeding women	[34]
Trigonella foenum-graecum (fenugreek seeds)	Powder from seeds and juice from leaves	It contains alkaloids like trimethylamine, neurin, choline, etc.; amino acids like leucine, isoleucine, histidine arginine, etc. Besides, vitamins C and B6, calcium, sodium, potassium, iron, and proteins are present in this herb	It is used to cure vitamin A deficiency disease called beriberi, mouth ulcers, boils, bronchitis, infection of the tissues beneath the surface of the skin (cellulitis), tuberculosis, chronic coughs, chapped lips, baldness, cancer and kidney ailments, etc. It is good for intestine, digestive system, gastritis, hair growth, post-pregnancy breast milk production, etc.	It is responsible for heartburn; extreme use of this can cause diarrhea, nausea, headaches, liver toxicity, harmful drop in blood sugar, etc. It is not safe during pregnancy, and it can produce birth defect in both animal and human	[35]

Foeniculum vulgare (fennel)	Powder from dry seeds, leaves, and flower	The main ingredients are trans-anethole, 2-pentanone, fenchone, and benzaldehyde-4-methoxy	Women use it for menstrual cramp. It is good for intestine and digestive system	It increases skin sensitivity to sunlight and makes sunburn more likely. It is not safe in large quantities during pregnancy. It can cause allergies, bleeding difficulties, and disruptions in hormone secretion, which can lead to breast cancer, uterine cancer, ovarian cancer, uterine fibroids, and other problems	[36]
Hibiscus rosa-sinensis (hibiscus)	Powder from dry petals and leaves	It contain tannins, anthraquinones, quinines, phenols, flavonoids, alkaloids, saponins, cyclopropanoids, methyl sterculate, 2-hydroxyserculate, malvalate, and beta-sitosterol; even minerals, proteins are also present	It helps to lower cholesterol, manage blood pressure, relieving menstrual pain, improve digestion, lose weight, even prevent cancer It has antibacterial, antidepressant, and antiaging properties. As it is good for hair growth, it has been used in hair care products, etc.	After all goodness, it has some side effects also. Like the people who has low blood pressure or hypotension, hibiscus is strictly prohibited It may cause dizziness, fainting, heart damage, etc. It also effects the estrogen levels due to which the hibiscus product is not applicable for women those are on birth control treatment or hormone replacement therapy	[37, 38]
Centella asiatica (gotu kola)	Juice from leaves	The primary active constituents of *Centella asiatica* are saponins or triterpenoids which include asiaticosides, in which a trisaccharide moiety is linked to the aglycone asiatic acid, madecassoside, and madasiatic acid	These triterpene saponins and their sapogenins are mainly responsible for the wound healing and vascular effects by inhibiting the production of collagen at the wound site. It has antidepressant properties, sedative and anxiolytic properties, antiepileptic properties, antioxidant properties, etc. It is	It has no such adverse effects, but it may cause skin allergy, burning sensations, headache, stomach upset, dizziness, and extreme drowsiness when consumed in large amount	[39]

(continued)

Table 2 (continued)

Herbs	Texture of extracted product and extracted portion	Active ingredients	Positive impact	Negative impact	References
			good for gastric ulcer, inflammation, etc.		
Hygrophila auriculata (kokilaksha)	Juice from leaves or entire plants	The whole plant contains lupeol, stigmasterol, isoflavone, glycoside, and alkaloid. Seeds contain asterol 1,2,3,4, astercanthine, histidine, lysine, phenylalanine, etc. Fresh flower contains apigenin-7-0-glucoside	The ash of dry plant is used to treat renal calculi, roots are used in the treatment of jaundice, and seeds powder is used to treat impotency, fewer sperm counts, and general debility Even it is known to increase hemoglobin in blood or purifier of blood	Some negligible side effects are found in this herb. Seeds are not suitable during pregnancy, and for regular use, consumers must consult with doctor	[40]
Andrographis paniculata (green chiretta)	Juice and paste of leaves	The leaves of *Andrographis paniculata* contain many bioactive compounds including diterpene, lactones, diterpene glucoside, flavonoids, etc. Some microparticles are polylactic-glycolic acid, alginic acid, and glucan derivatives. Several nanoparticles are polymeric nanoparticles, solid lipid nanoparticles, gold nanoparticles, nanocrystal, and micro and nanoemulsion Its bioavailability was obtained by a lipid combination of lecithin, glyceryl behenate, glycerol monostearate, and surfactant solution 3% Tween-80	As it is a bitter herb, it is good for diabetes and blood circulation or purification. It is good for liver disease, influenza, common cold, appetite stimulant, stomach ulcers, and inflammation. It has antioxidant properties due to which it reduces toxicity of hydrogen peroxide, hydroxyl radical, and singlet oxygen those are responsible for oxidative stress It is also used for leprosy, pneumonia, tuberculosis, malaria, cholera, rabies, and even HIV/AIDS	It is safe up to 340 mg per day; otherwise, it can cause side effects such as diarrhea, vomiting, rashes, headache, runny nose, and fatigue. It is unsafe during pregnancy when taken by mouth, as it cause miscarriage Andrographis might cause slow blood clotting and reduce blood pressure	[41, 42]

well-liked plants, *Moringa oleifera*, has a number of important health advantages. The *Moringa oleifera* leaf extracts are helpful in preventing the main symptoms of diabetes mellitus, including effective control of blood sugar or insulin levels, improvement of insulin tissue sensitivity, and protection against organ damage under long-term hyperglycemia. *M. oleifera* leaf and seed extracts show enhanced effects in strengthening intracellular antioxidant defense like catalase, superoxide dismutase, and glutathione to lower lipid peroxidation products and repress pro-inflammatory markers like tumor necrosis factor-α, interleukin (IL)-β, and monocyte chemoattractant protein-1 [46]. Skimming, one of the key pharmacological active compounds found in *Hydrangea paniculata*, lowers blood urea nitrogen (BUN) and urine albumin excretion (UAE),urine albumin excretion (UAE) and suppresses interleukin-1 (IL-1).Reduces the expression of interleukin-1 (ILK1) and IL-6. This can significantly meliorate renal function and suppress the immune complex deposition [47]. Inhibiting lipid accumulation in adipocytes and boosting lipolysis are effects of consecutive water and methanol extracts of *Nelumbo nucifera* petals. Furthermore, preparations of *Nelumbo nucifera* petals clearly exhibit agonist and antagonist actions against cannabinoid and serotonin receptors, respectively [48]. For both type 2 diabetes and hyperuricemia, the extract from the leaves of the *Morus alba* plant may be a great alternative [49]. Andrographolide, major diterpene lactones found in *Andrographis paniculata*, exhibits notable inhibitory effects on various cancers. By decreasing the transcriptional and translational levels of VEGF, EGFR, cyclin A, and cyclin B expression, it inhibits the growth of tumors. Additionally, *Andrographis paniculata* extract has anti-infective, anti-inflammatory, antioxidant, immunostimulant, and antidiabetic properties [50, 51]. The fruits of *Pterodon pubescens* are frequently used to treat respiratory disorders, sore throats, and rheumatic diseases. By lowering blood sugar, cholesterol, and triglyceride levels, the ethanolic extract of *P. pubescens* also exhibits anti-inflammatory and antinociceptive properties and prevents mechanical and thermal hyperalgesia in the postoperative pain [52–54]. Different constituents like vitamins, flavonoids, minerals, etc., are found in the different parts of *Carica papaya* that develop different functions such as antidiabetic activity, wound healing activity, antimalarial activity, etc., for preventing disease. *C. papaya* seeds water extract also acts as a potent free radical scavenger, providing protection to Detroit 550 fibroblasts that underwent H_2O_2 oxidative stress by its antioxidant effect [55, 56]. Jian-Pi-Shen formula has [composed of *Astragalus mongholicus* Bunge, *Atractylodes macrocephala* Koidz., *Dioscorea oppositifolia* L., *Cistanche deserticola*, *Wurfbainia compacta* (Sol. Ex. Maton) Skornick and A.D. Poulsen, *Salvia miltiorrhiza* Bunge, *Rheum palmatum* L., and *Glycyrrhiza glabra* L.] enhanced perindopril suppression of chronic kidney disease progression by increasing the expression of SIRT3, modulation of mitochondrial dynamics, and antioxidant effects [57]. Ca^{2+} is mobilized by bergamot essential oil (BEO) from *Citrus bergamia* Risso from extracellular and intracellular sources in endothelial cells through IP3-mediated Ca^{2+} release and affect the promotion of Ca^{2+} influx via an SOC mechanism [58].

5.2 Alzheimer's Disease

The most common neurodegenerative ailment, Alzheimer's disease (AD), produces progressive dementia by limiting mental capacity development and obstructing neurocognitive function [59]. *Ginkgo biloba* extract has positive effects on issues with insufficient blood flow, loss of consciousness, depression, and headaches. The attenuation of apoptosis, an anti-inflammatory effect, an inhibition of membrane lipid peroxidation, and an inhibition of the development of amyloid aggregates are only a few examples of the molecular and cellular mechanisms that are shown [60]. Due to the presence of curcumin, which inhibits plaque formation in the brain, oxidative stress, and amyloid pathology, and regulates a number of transcription factors connected to inflammation, *Curcuma longa* has anti-inflammatory effect against Alzheimer's disease [60, 61]. *Melissa officinalis* (also called lemon balm) extract contains rutin as the main flavonoid compound, and the primary phenolic ingredient, rosmarinic acid, enhances brain-derived neurotrophic factor and nitric oxide synthase gene expression to improve memory in Alzheimer's patients. The ability to reduce agitation is another benefit of *Melissa officinalis* extract [62, 63]. *Panax ginseng* extract contains ginsenosides and gintonin that contribute to AD amelioration by inhibiting Aβ-induced neurotoxicity, activating nonamyloidogenic pathway to reduce Aβ formation and enhancing acetylcholine and choline acetyltransferase expression in brain. *Ficus racemosa* is known to have the same function to prevent this disorder [64, 65]. Therapeutic benefits of the class of chemicals known as bacoside-A, which are derived from the *Bacopa monniera* plant, include memory and cognitive function enhancement. Bacoside-A significantly reduces cytotoxicity, fibrillation, and in particular the interaction of amyloid-beta (1-42) (Aβ42) with membranes, a peptide important in the progression and toxicity of Alzheimer's disease [66, 67]. Besides, plants such as *Salvia officinalis, Punica granatum, Rosmarinus officinalis*, etc., have significant effects in Alzheimer's disease prevention by AchE and BchE inhibition, antioxidant activity, neuroprotective activity, anticholinesterase activity, etc. [59].

5.3 Metabolic Syndromes

The metabolic syndrome is a collection of factors that increase the risk of developing cardiovascular disease, such as central obesity, insulin resistance, glucose intolerance, dyslipidemia, and hypertension. People who have the metabolic syndrome are more likely to suffer from peripheral vascular disease, stroke, and coronary heart disease, as well as other conditions caused by plaque formation in artery walls.

A Chinese herbal extract SK0506, a mixture of active ingredients of *Gynostemma pentaphyllum, Coptis chinensis*, and *Salvia miltiorrhiza,* is known to have endpoint effects on impaired glucose tolerance, hyperinsulinemia, and hyperlipidemia, and on visceral obesity. This oral agent may have the antidiabetic property to prevent type 2 diabetes [68, 69].

5.4 Urinary Tract Infection

Urinary tract infections (UTIs) are very common infection. In a study, cranberry products were found to be effective than antibiotics for the prevention of recurrent UTIs in women. Furthermore, *Rosa canina* has the potency to prevent UTI in women undergoing a caesarean section [70].

5.5 Malaria

One of the most serious parasite diseases in the world and a major killer, especially in underdeveloped nations, is malaria [71]. Hexanic extract of *Xylopia aromatica* root wood, *Xylopia emarginata* root bark, *Casearia sylvestris* var. *lingua* leaves, stem wood, and stem bark, and *Cupania vernalis* leaves was found to have the strongest antiplasmodial activity [72]. K1 strain of *Plasmodium falciparum* can be foreclosed by the antimalarial activity of 80% EtOH extract of *Goniothalamus marcanii* [73]. Leaf ethyl acetate and methanol extract of *Phyllanthus emblica* and flower bud extract of *Syzygium aromaticum* also may serve as antimalarial agents even in their crude form [74].

5.6 Cholera

Saraca indica bark extract exhibits various pharmacological effects such as antioxidant activity, anti-breast cancer activity, and vibriocidal activity [75, 76]. Along with *S. indica,* ethanolic extract of *Lawsonia inermis*, *Syzygium cumini*, *Terminalia belerica*, and *Allium sativum* are also known to have anti-vibrio potential to prevent cholera [76].

5.7 Pneumonia

In a study, Zamzam water extract of *Echinops adenocaulos* and aqueous extract of *Urtica urens* was detected to have antibacterial activity against multidrug-resistant strain of *S. pneumonia* [77]. The acetone, hexane, and methanol fractions of *Parietaria judaica* exhibit antibacterial activity, while the potent antifungal activity against *Candida albicans* has been found in the acetone fraction. Besides, the fractions have strong cytotoxic and antiproliferative activity against HeLa cancer cell [78]. Additionally, due to its antibacterial properties, the crude extract of *Beta vulgaris* leaves can suppress the growth of *Klebsiella pneumoniae* [79].

5.8 Typhoid

MA 001, manufactured from *Citrus aurantifolia*, *Spondias mombin*, *Lantana camara*, *Bidens pilosa, Trema occidentalis, Psidium guajava, Morinda lucida, Vernonia amygdalina, Persea americana, Paullinia pinnata, Momordica charantia*, and *Cnestis ferruginea* medicinal herbs, has been utilized for the treatment of typhoid fever [80].

5.9 HIV

Prostratin, an antiviral substance made by *Homalanthus nutans*, shows substantial antiviral activity against multiple strains of HIV-1 and HIV-2 and has been utilized in traditional Samoan herbal medicine to treat "yellow fever" (hepatitis) and other viral illnesses. Prostratin interacts with a cellular target required for viral entry in order to predominantly impede the entry step of the HIV replication cycle [81, 82].

6 Acceleration on Herbal Medicine Development Involving Metabolic Engineering, Synthetic Biology, and Systems Biology

Many naturally occurring substances that are derived from plants have numerous pharmacological and medicinal uses. The creation of medicinal plant natural products (MPNPs) results from specialized plant metabolism. This is accomplished by a variety of enzymes from diverse classes that catalytically convert core metabolites into secondary metabolite molecules like terpenoids like artemisinin and paclitaxel, alkaloids like camptothecin, and polyketides (PKs) like flavonoids. However, because of their slow growth, limited yield, prolonged time requirements, and intricate structural design, these compounds are relatively difficult to acquire. Consequently, there has been a rise in the demand for their industrial output [83–85]. Traditional metabolic engineering and ideas from systems biology are combined in synthetic biology, a brand-new branch of contemporary multidisciplinary life science and systems science. Due to recent developments in synthetic biology and supporting technologies like DNA synthesis, sequencing, and analytical techniques, many natural products of plant origin are not synthesized by microorganisms. As a result, metabolic and protein engineering have advanced to the point where both can be used to engineer the biosynthesis of a specific medicinal molecule by developing engineered microorganisms. Optimized and transformed organisms are characterized by environmental friendliness, low carbon emission, and economic effectiveness. They can continuously and successfully synthesize specified target molecules with high yield. Instead of depending simply on the traditional discovery and separation or difficult synthetic chemistry to obtain a restricted number of herbal pharmaceuticals, many natural drugs and analogues can now be manufactured fairly inexpensively by creating new biosynthetic pathways [84, 86–89]. The biosynthesis of herbal medicines like artemisinin, paclitaxel, tanshinone, noscapine, etc., is used as an example to demonstrate how scientific advances in synthetic biology can be used for the synthesis of natural plant compounds.

6.1 Selection of Host Species for a Heterologous Plant Pathway to Overproduce MPNP Precursors

The choice of the ideal host species for the pathway to be engineered is the first step in the heterologous production of MPNPs. Based on characteristics including ease of cloning, culture, and appropriateness for the new enzymes and chemicals, host species are chosen. The first host species of choice for the production of MPNPs may be plant cells. For instance, *Nicotiana benthamiana* is a promising heterologous host to manufacture cannabinoids in planta because of its high transformation rate, natural capacity to accommodate the supply of precursor GPP, and assistance in redirecting the current pathway towards cannabinoid synthesis. However, the fundamental disadvantage of employing plant species as hosts is that they are very sluggish in comparison to microorganisms; for this reason, microbial hosts are frequently preferred [84, 89, 90]. The most popular tools for genetic modification are *Escherichia coli* and *Saccharomyces cerevisiae* because they are simple to cultivate, have a variety of platform strains available, and have the ability to produce too much of the desired substance [91, 92]. Additionally, the growth of *Corynebacterium glutamicum* strains results in the commercial production of amino acids such as L-arginine and L-proline [93]. Any bacterial or plant species can serve as a model organism. Their metabolic pathways have been extensively studied and can be utilized to direct the overexpression and knockout modification of certain enzymes and genes for the overproduction of important metabolite precursors. Due to the complexity of cellular metabolism, the synthesis portion of metabolic engineering of *S. cerevisiae* is comparably excessive while the analysis portion is limited. In order to mimic the subcellular localization used in MPNPs biosynthesis in plants, cellular microcompartments like mitochondria and peroxisomes can be used [92, 94, 95]. The doubling time of *E. coli* is 3–4 times shorter than that of *S. cerevisiae*, suitable for the very high expression of enzymes, and has a different profile of native metabolites available compared to *S. cerevisiae*. Therefore, it is thought that both strains of *E. coli* and *S. cerevisiae* as well as numerous other plant species are possible hosts that, following genetic manipulation, produce an excess of alkaloids, terpenoids, flavonoids, and other therapeutic chemicals.

6.2 Increasing Precursor Supply

Enhancing precursor supply is a successful method for the high synthesis of important medical natural compounds that may be used to native and heterologous generating strains. Serpentine, strictosidine, ajmalicine, and other monomeric indole alkaloids, as well as dimeric indole alkaloids like vinblastine and vincristine, are all produced by *Catharanthus roseus* [96]. Significantly, more distinct alkaloids are synthesized when upstream rate-limiting enzymes like geraniol synthase, secologanin synthase, and MAP kinases are overexpressed [97]. The overexpression of hyoscyamine 6β-hydroxylase (H6H) (key enzyme for the conversion of hyoscyamine to scopolamine) increases the scopolamine production in *Datura innoxia* hairy roots [98]. The overexpression of codeinone reductase (CodR) significantly increased the amount of codeine and morphine in transgenic hairy roots lines of *Papaver bracteatum* [99]. Foreign enzymes from other plant species may also aid in the production of specific metabolites. For example, the overexpression of *hyoscyamine* 6β-*hydroxylase* genes of *Hyoscyamus niger* in hairy root cultures of *Scopolia lurida* and the expression of heterologous *Vitreoscilla* hemoglobin in the hairy roots of *Hyoscyamus niger* enhance the accumulation of scopolamine [100, 101]. In *Panax ginseng* root culture, the overexpression of ginsenosides biosynthetic pathway key gene PgSQS1, responsible for upregulating the expression of SE, β-amyrin synthase, and cycloartenol synthase, results in increase of phytosterols and ginsenosides [102, 103]. The overexpression of linalool synthase (LIS) gene from *Clarkia breweri* in *Lavandula latifolia* plants increased the linalool content up to tenfold [104]. The accumulation of anthocyanins has boosted output and yield as a result of the overexpression of MYB transcriptional factors. Hop plants were genetically modified by Agrobacterium utilizing MYB transcription factors from *A. thaliana*, which resulted in a definite increase in flavonoid synthesis [105]. The use of microorganisms for the manufacturing of medical products has drawn interest as a solution to the challenging downstream plant extraction process and poor production. A strategy was used by Fowler et al. to find and validate fresh genetic alterations that would increase flow to malonyl-CoA and boost the production of flavonoids in *E. coli* [106]. Coenzyme ligase (4CL) from *Medicago truncatula* and chalcone synthase (CHS) from *Vitis vinifera* has been expressed in *S. cerevisiae* that resulted 28-fold increased production of naringenin [107]. Martin et al. increased the generation of isoprenoid precursors in *E. coli* by introducing the MVA route from *S. cerevisiae* [108]. Amorphadiene synthesis was boosted in *S. cerevisiae* by increasing the flow from pyruvate to acetyl-CoA in the MVA route through overexpression of acetaldehyde dehydrogenase and the insertion of a *Salmonella enterica* acetyl-CoA synthetase variation [109]. The metabolic engineering of photosynthetic organisms has also increased the production of terpenoids [110].

6.3 Engineering Pathway-Specific Components

Numerous factors, including the modification of regulatory elements, the management of pathway elements, protein engineering, etc., are taken into account while constructing the most efficient pathway for the production of therapeutic natural products. For instance, the positive regulator of antibiotic synthesis has been identified as the gene clusters producing the Streptomyces antibiotic regulatory protein

(SARP). The production of antibiotics by *Streptomyces griseus* has increased by about six times when the SARP from the *fdmR1* has been overexpressed [111, 112]. The transcriptional and translational control of individual enzyme may be a promising approach to fine-tune metabolic pathways but determining the proper enzyme level can be challenging [88]. For example, an inducible promoter system was utilized to determine optimal expression levels for each gene in *S. cerevisiae* for the production of benzylisoquinoline alkaloids [113]. Additionally, it may be possible to modify enzymes through evolutionary engineering to boost the pathway's effectiveness.

6.4 Suppression of Competitive Pathways and Gene Editing

The elimination of competitive pathways that can obstruct the native biosynthetic pathway for the manufacture of specific desired products is another tactic, as is the downregulation or deletion of specific genes. For instance, *Artemisia annua* produced significantly more artemisinin when the expression of SQS, a crucial gene of the sterol route (competitive process of artemisinin biosynthesis), was suppressed by RNA interference (RNAi) [114]. By using RNA interference (RNAi) technology, the lycopene ϵ-cyclase (LCY-ϵ) gene was downregulated, which resulted in a 21-fold increase in the amount of β-carotene in sweet potato transgenic calli [115]. To improve NADPH availability (the limiting factor of high flavonoid production) and boost flavonoid production in *E. coli*, a combination of gene knockouts was identified [116]. The output of (+)-valencene in *N. benthamiana* plants increased somewhat after the endogenous 5-epi-aristolochene synthase and squalene synthase, which compete for the FPP pool, were silenced [117]. Higher plants are incapable of homologous recombination; therefore, they cannot delete a particular gene. However, the CRISPR/Cas9 technology for gene editing has recently solved this problem [110, 118]. For example, using a CRISPR/Cas9 approach, Zakaria et al. introduced detrimental mutations into *hss* gene encoding *homospermidine synthase* (HSS) in *S. officinale* that successfully eliminated pyrrolizidine alkaloids which are toxic to humans [119].

6.5 Designing New Precursor Biosynthetic Pathways

There are numerous methods that can be used to build a novel biosynthetic pathway in a heterologous host. This entails disassembling a pathway into its component parts, each of whose unique enzymes is evaluated and optimized in a host before being combined when fully assembled. Horinouchi et al., for instance, divided the biosynthesis of flavonoids into three modules: substrate synthesis, PK synthesis, and post-PKS modification. In *E. coli*, known PKs were produced by altering these three plasmid components and combining them with precursor-directed biosynthesis

[84, 120]. An IPA method for terpenoids synthesis was created by Clomburg and colleagues [121] that could convert isoprenoid precursor with the fewest possible steps. The healing plant *C. roseus* produced numerous chlorinated alkaloids when bacterial tryptophan halogenases were added [122]. The quickest, ATP-independent pathway from formaldehyde to acetyl-CoA was created by Lu et al. by reusing glycolaldehyde synthase and acetyl-phosphate synthase [123].

6.6 Protein Engineering

An important tool for changing the substrate specificity of biosynthetic enzymes, protein engineering is a process by which a protein sequence is altered by substitution, insertion, or deletion of nucleotides in the encoding gene [124]. This process increases the effectiveness of enzymes for the development of biocatalysis. By creating a synthetic chimeric *bidomain P450* that could mimic the structure of the bacterial *P450BM-3*, Koffas et al. were able to improve the rate at which isoflavones were produced in *E. coli* [125]. By using a pair of short peptide tags (RIAD and RIDD) that increased the carotenoid synthesis in *E. coli* by 5.7 folds, Kang W and colleagues constructed a scaffold-free enzyme assembly [126]. It may be advantageous to use these powerful metabolic engineering tools to successfully generate the intended medicinal herbal medicines. Metabolic engineering of artificial but natural therapeutic compounds. By knowing the pathways and the related enzymes, this goal may be accomplished.

7 Regulations and Bioethical Concerns with the Use of Herbal Remedies for Illness Prevention and Health Management

7.1 Adverse Effects of Herbal Medicine on Health

In spite of having the beneficial aspects of medicinal herbal products, many medicinal plants exhibit undesirable reactions that can cause serious injuries and life-threatening conditions. Like all effective synthetic drugs, herbal medicines are also associated with different drug reactions including toxicity (nephrotoxicity, hepatotoxicity, cardiotoxicity, neurotoxicity, and skin toxicity) and overdose, drug-herb interaction, allergic reaction, etc. The toxicity can occur due to the excessive dosage intake, misuse of herbal medicine, self-treatment, and environmental factors [127, 128]. Although *Ginkgo biloba* plant extracts seem to be safe for humans' health, they may also be the cause of the herb's toxicity, genotoxicity, and carcinogenicity, as well as its unpleasant side effects include headaches, vertigo, restlessness, nausea, vomiting, diarrhea, and skin sensitivity [129, 130]. A study by Liu et al. demonstrated the aconite poisoning after the ingestion of traditional Chinese medicine containing *Aconitum carmichaelii*, as it contains poisonous alkaloids [131]. The overdose of combination of *Aconitum kusnezoffii* and *Aconitum carmichaelii* has shown the toxic effects as bradycardia and hypotension. But the correct dose after processing would not result in bradycardia as the toxicity of aconite reduces due to processing [132]. Administration of *Glycyrrhiza glabra* has been linked to adverse reactions such as hypertension and secondary disorders brought on by hypokalemia. Subacute exposure to *G. glabra* causes the adrenal-pituitary axis to become inhibited and lowers the amount of iron in the liver [133]. The nephrotoxicity of different plants have been shown. For example, *Tripterygium regelii* Sprague et Takeda poisoning heads to acute kidney injury and renal failure. *Rheum palmatum L.* and its anthraquinone compounds can lead to renal damage under certain condition. *Averrhoa carambola L.* contains oxalate in high quantity that causes kidney damage. *Guaiacum officinale L.* and *Arctostaphylos uva-ursi* increase formation of stone [128, 134]. As a type IV hypersensitivity reaction to urushiol, *Toxicodendron diversilobum* (poisonous oak) and *Toxicodendron rydbergii* (poison ivy) are the most often occurring plants to cause allergic contact dermatitis [135]. St. John's wort, or *Hypericum perforatum*, has side effects such as allergic reactions, headaches, dizziness, restlessness, nausea, vomiting, constipation, and more [21].

7.2 Overview of Regulatory Aspects and Approval of Herbal Medicine

Different countries have their own legal policy to regulate the usage of herbal drug. This is because of the adverse effects due to poor quality or improper use, cultural aspects, and the lacking scientific study on herbal medicines. In order to establish the fundamental standards for evaluating the quality, safety, and effectiveness of herbal medicines, the WHO has developed recommendations [136]. Below is a quick description of the regulatory frameworks of several, chosen nations. The Department of AYUSH is the regulating body, and the Department of Drugs and Cosmetics (DAC) Act of 1940 and the Cosmetic Laws of 1945 regulate herbal drugs in India. The Indian System of Medicine (ISM) is being expanded, and the Department of AYUSH is in charge of defining standards, regulating, promoting, and supervising it. The Department of Indian Medicine and Homoeopathy (ISM & H) was founded in 1995 with the goal of encouraging assistance to the public in regards to safe and effective services that satisfy pharmacopoeial requirements and AYUSH quality standard [137]. This department employs AYUSH to obtain wonderful health [138]. In Malaysia, any herbal product falls under the regulated product category. Anyone in the marketing industry who wants to sell a herbal product must first register it. Traditional items and health supplements are the two categories under which these items may be registered with the Malaysian Registrar of Businesses or Suruhanjaya Syarikat Malaysia [138].

In Australia, the Therapeutic Goods Act 1989, which governs therapeutic products, regulates both complementary and herbal medicines. A two-tiered method was created for the regulation of medicinal commodities based on risk. Because they may be made from pre-examined materials, complementary medications are thought to carry a lesser risk and are not reviewed before being released. However, there are individual assessments for the licensed medications' effectiveness, quality, and safety [139]. The US Food and Drug Administration categorized the botanical items as a medicine, food, or dietary supplement based on the claims and intended use. According to the FDA, the medication must be sold under an NDA that has been authorized. In accordance with the Dietary Supplement Health and Education Act of 1994 [140], the US FDA controls goods advertised as dietary supplements. Natural health products (NHPs) are what are referred to as "Classified as Medicines" in Canada, which is how the majority of natural goods are categorized. These fall under the 2004-enacted Natural Health Product Regulations (NHPR), which are overseen by Health Canada (HC). Additionally, a collection of NHP monographs has been created, to which an application may certify as their sole source of proof of efficacy and safety [141].

8 Conclusion and Future Perspectives

Due to its economic significance, traditional medical treatment employing herbal medicine is a fast expanding healthcare system that is now widely employed in many nations across the world. Numerous types of categorized herbs have been shown to contain numerous medicinal components, including alkaloids, flavonoids, terpenoids, saponins, etc., that have demonstrated antibacterial and antifungal actions. Research is being done on several plants that might be helpful in the prevention of many deadly diseases, and the idea of a medical natural substance having multiple uses is gaining popularity [142]. The majority of herbal natural goods are produced using conventional methods; however, these methods' main drawback is the product's poor yield. The large-scale industrial manufacturing of the required pharmaceutical goods has been made possible by advances in our understanding of the metabolic and regulatory networks at the genome level, as well as natural product biosynthetic pathways [143]. For the high output that is detailed in Fig. 1, several metabolic engineering components, such as protein engineering, pathway engineering, etc., as well as synthetic biology and systems biology, have been extremely helpful tools. Along with the advantages of herbal therapy over modern treatment, concerns about adverse reactions are also becoming more prominent [144]. Since "safe" and "natural" are not the same thing, herbal medicines should not always be taken for granted just because they come from sources that are deemed to be "safe." Therefore, the three most crucial factors in herbal therapy are safety, effectiveness, and quality control. As a result, it is imperative that worldwide regulatory standards for herbal medicine be established,

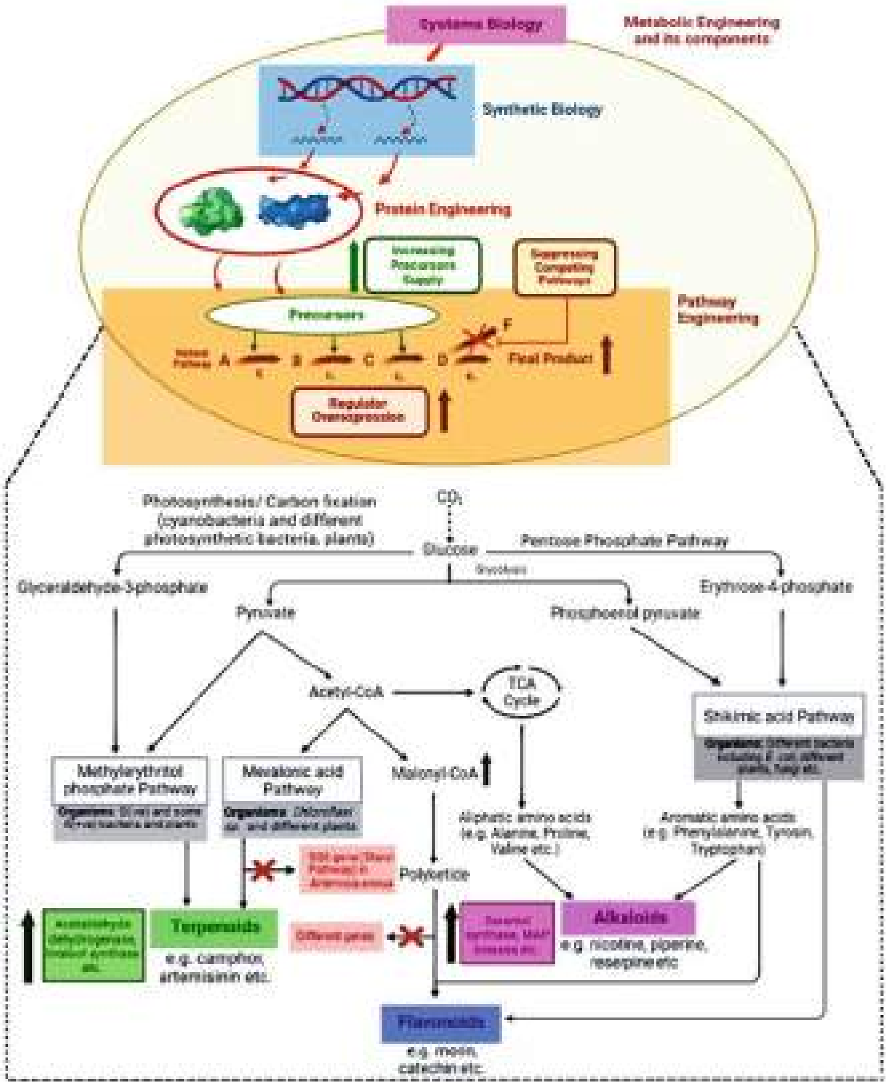

Fig. 1 Putative metabolic engineering and synthetic biology tools for microbial production of herbal-based medicines towards health management and disease prevention

and all national regulatory agencies must take aggressive measures to safeguard the public's health by guaranteeing the efficacy and safety of herbal remedies. The conclusion drawn from this chapter is that herbal medicine may prove to be a viable replacement for synthetic chemical-based medications.

Acknowledgment Authors would like to thank JIS University and JIS Group of educational initiatives for their encouragements.

Abstract

A comprehensive healthcare system, African traditional medicine is divided into three degrees of specialization: divination, spiritualism, and herbalism. The traditional healer offers medical treatments in accordance with the predominant cultural and religious ideas, knowledge, and attitudes in his society. The belief that illness has both natural and supernatural origins necessitates its treatment via both physical and spiritual methods, including divination, incantations, animal sacrifice, exorcism, and the use of herbs and other natural remedies. The use of herbal medicines involves integrating a number of therapeutic techniques from indigenous medical systems that may date back many generations. This integration frequently yields helpful instructions for the choice, preparation, and application of herbal formulations for the treatment, control, and management of a wide range of illnesses. Herbal medicine has been used in Africa since ancient times and is being used now via divination, interviews, medical reports, and viewpoints from both the spiritual and physical realms. Despite the current improvements in mainstream medicine, the use of herbal medicines for basic healthcare needs in Africa is still on the rise significantly. The African Perspective of Illness and Disease, Herbal Medicine in Africa, Clinical Practice of African Traditional Medicine, Some Traits in Herbal Medicine Practices from Selected African Countries, Factors Responsible for Increased Usage of Herbal Medicine in Africa, Adverse Effects of Herbal Medicine, Influence of Regulatory Policies in Safety of Herbal Medicine, Challenges of Monitoring Safety of Herbal Medicines are discussed in this chapter.

1 Introduction

Herbal medicine, often known as herbalism, is the method used by a civilization to cure, identify, and prevent disease that are not based on scientific evidence. It is context-specific since it is determined by a culture's knowledge and values, much as social constructions and risk negotiations. These methods become "complementary, non-conventional or alternative medicine" [1] when contemporary civilizations embrace them outside of their original setting.

As a result, traditional medicine (TM) native to the many African civilizations is known as African traditional medicine (ATM). African traditional medicine is well renowned for providing essential healthcare to address the psychological, emotional, spiritual, cultural, and social requirements of the African people, and it is notably thought to be safer than manufactured medications due to its natural ingredients [2]. Traditional herbal medicine (THM) has been around since at least the Stone Age. It seems that traditional healing and magic are significantly more prevalent than Western medicine in Africa [3, 4] and are much older than certain other traditional medical professions. African traditional medicine is a comprehensive healthcare system with three levels of specialization: divination, spiritualism, and herbalism [2, 5]. In certain cases, these specializations may overlap.

Herbal medicine is the most often used and favored form of TM treatments out of all of them [6, 7]. Many individuals have started using herbal therapy as a supplement to or an alternative to allopathic treatment as the practice gains greater international acceptance [8, 9]. According to available data, 80% of Africans [10–12] depend on herbal medication for their basic healthcare (PHC) requirements. This use of herbal medicines is supported by a wide range of factors. These explanations vary depending on the culture and ethnicity. The availability and accessibility of herbal medications, their efficacy, safety, cost, and their cultural compatibility are often cited justifications for their usage [13].

In many emerging African nations, the availability of herbal medications far surpasses that of allopathic treatments. Therefore, the majority of individuals turn to herbal remedies when they are unwell or are having health issues. The extensive usage of herbal remedies in Africa and other underdeveloped nations may also be explained by the ease with which practitioners can get them [14]. There are hardly many allopathic doctors in rural settings; they are mostly found in metropolitan regions.

Therefore, according to Abdullahi [15], traditional healers, especially herbal medicine practitioners, continue to be the primary source of health icare for millions of people living in rural areas. The African Perspective of Illness and Disease, Herbal Medicine in Africa, Clinical Practice of African Traditional Medicine, Some Traits in Herbal Medicine Practices from Selected African Countries, Factors Responsible for Increased Usage of Herbal Medicine in Africa, Adverse Effects of Herbal Medicine, Influence of Regulatory Policies in Safety of Herbal Medicine, Challenges of Monitoring Safety of Herbal Medicines are discussed in this chapter.

2 African Perspectives of Illness and Disease

In an African culture, there is a justification for why a person is afflicted with a certain illness at a specific period. Ayodele [16] asserts that sicknesses are often caused by witchcraft or sorcery, deities or ancestors, as well as being inherited and occurring naturally. A sick person is seen differently by African culture than by Western allopathy. Natural, cultural, and societal factors are often cited as the sources of sickness [17]. Cultural or sociological illness is said to be linked to supernatural causes like angered spirits, witchcraft, or alien/evil spirits, even for conditions that are now recognized as well as understood in modern medicine, such as hypertension, sickle-cell anemia, cardiomyopathies, and diabetes. According to ancient African tenets, a person's identity is comprised of their body, soul, conscience, and society. If all three factors were well-balanced, it would be a sign of great health; otherwise, it would point to illness.

As a result, the physical health of a patient is just one part of treatment that may improve their emotional, moral, and social well-being as well. African traditional medicine is distinct from complementary and alternative medicine in a number of ways. For example, many African cultures practice faith healing (spiritual healing), therapeutic occultism, male and female circumcision, tribal marks, treatment for snake bites, treatment for whitlow, removal of tuberculous lymphadenitis in the neck, cutting of the umbilical cord, ear piercing, removal of the uvula, extraction of a carious tooth, abdominal surgery, and other infections [18]. African traditional medicine cannot be seen as an alternative since it is the continent's original system of healthcare.

3 Herbal Medicines

Herbal medicine (HM) is a part of African traditional medicine and is sometimes used interchangeably. It is the oldest and still widely used kind of medicine in the world [19]. HM is used by people of many cultures and socioeconomic backgrounds [20, 21]. Herbal medicines are defined by the World Health Organization (WHO) as those that contain whole plants, parts of plants, or other plant materials (such as leaves, bark, berries, flowers, roots, and bark), and/or their extracts, for therapeutic use or for other benefits in humans and sometimes animals.

The traditional healer, or herbalist, in the unique and well-known discipline of herbal medicine specializes in the use of plants to treat a wide variety of ailments. They play a pivotal role because of their comprehensive knowledge of the pharmaceutical procedures necessary to turn native plants into medicines. It seems that the use of herbal treatments is common in all cultures. However, even in cases when the same ailment is being treated, the plants employed and the therapeutic approach are different from one region to another [22, 23]. Medicinal plants are plants whose organs make up various compounds, which can be used for treatment of ailments [24–56]. Some herbs, for instance, have been used for decades in traditional medicine despite a lack of scientific proof supporting their efficacy. In this context, crude medicines of natural or biological origin refer to these plants in whole or in part due to their medicinal properties. Medicines may be classified as “organised” or “unorganised” based on whether they are made from plant parts that include cells, such as leaves, bark, roots, etc., or from acellular plant components [57].

Herbal medication is widely accessible and affordable compared to contemporary allopathic treatment [58, 59]. Because common medicinal plants are generally well known, particularly in rural regions, there is less need for consultation with traditional healers, except for the treatment of chronic disorders [58]. Even in cases when traditional healers consult, there is a lack of agreement among them on the methods for making herbal remedies and the appropriate dose [60]. However, in Africa, at least 80% of people depend on medicinal plants for their healthcare, according to WHO [61]. Herbal medications have a number of benefits, including cheap cost, accessibility, acceptance, and what seems to be minimal toxicity [62, 63].

In many parts of Africa, traditional healers still possess the knowledge of the plant species used and the techniques for making and giving the treatment, particularly for critical illnesses. The use of these drugs is still shrouded in secrecy and rivalry, and healers are often reluctant to impart their expertise to anybody other than close friends [64].

3.1 Methods of Preparation and Administration

Diffent techniques or methods have been employed in the preparations of traditional medications according to different cultures and their geographical locations. Various plant materials in dried and fresh states are been used. For the sake of this chapter a particular approach has been outlined, which can bring about the herbal medication efficacy and safety. A few common preparation techniques are shown in Fig. 1:

Lotions, which are diluted liquid treatments applied to the skin, and liniments, which are applied topically, come in liquid, semiliquid, and oily forms that all include the active components. Freshly macerated plant components are used to make poultices, which are then applied to the skin. Snuff is dry, powdered plant material that is inhaled via the nasal passages. Plant charcoal is produced when dried plants are burned. Sometimes mixtures made from many plants are developed to maximize the benefits of the composite plants [65, 66].

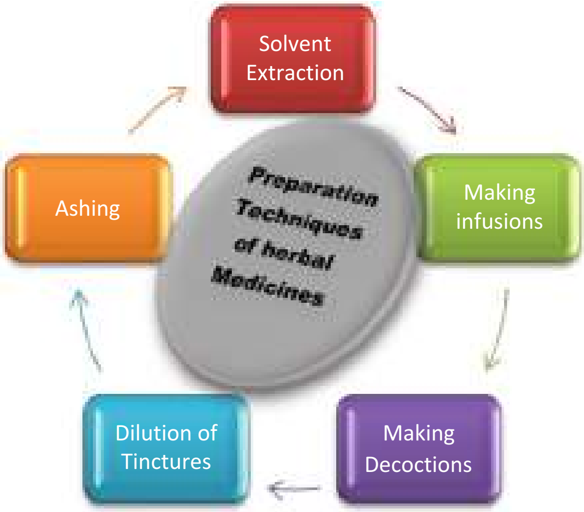

Fig. 1 Preparation techniques of herbal medicine

3.2 Ethnobotanical Surveys

Through ethnobotanical surveys, which look at plants in connection to human culture, information about plants is gathered. Although several plants are utilized in traditional African medicine, little is known about their active components. Ethnobotanical surveys engage with the local population and their surroundings; as a result, they are participatory methods that allow the community to share their knowledge of the plants' practical use [67]. This might entail identifying, preserving, documenting, and using therapeutic plants. The majority of ethnomedical data lacks adequate validation. Despite the fact that many writers have published a wealth of information on plants with medicinal properties in Africa [62, 66]. These provide a wide range of data for scientific validation and investigation [68].

Many chronic illnesses may be effectively treated by using plants as medication. For instance, according to information from Nigerian folkloric medicine, *Ocimum gratissimum* is used to cure diarrheal disorders whereas *Rauvolfia vomitoria* is used to treat hypertension and other nerve problems. Others include *Garcinia kola* seeds for pain and inflammation, *Aloe vera* for skin conditions, *Carica papaya* seeds for intestinal parasites, *Citrus paradise* seeds for resistant urinary tract infections, and pure honey for treating chronic wounds [69–73].

For plants from other African nations, the same is true [74]. The majority of these curative qualities have been known for a while thanks to observations supported by evidence. Scientific studies aim to comprehend the plant chemical components viz-a-viz their medicinal benefits. A plant's therapeutic action is a result of its intricate chemical makeup, with various plant sections having various therapeutic benefits. Alkaloids, glycosides, tannins, acids, coumarins, sterols, phenols, and other chemical compounds present in plants are what give rise to the diverse therapeutic actions

[75, 76]. Many current drugs have been based on these substances or were first produced from them. For instance, aspirin is made from salicylic acid, which is obtained from the bark of *Salix alba* and the meadowsweet plant, *Filipendula ulmaria* [77].

Antimalarial medications include artemisinin and quinine, which are derived from the bark of the *Artemisia annua* plant. Leukemia is treated with the anticancer medications vincristine and vinblastine, which were produced from the Madagascar periwinkle (*Catharanthus roseus*). While digitoxin is a cardiac glycoside produced from the foxglove plant (*Digitalis purpurea*), morphine and codeine, which are derived from the opium poppy (*Papaver somniferum*), are used to treat diarrhea and provide pain relief [74, 78].

Additionally significant resources for the cosmetic industry are medicinal plants. As synthetic chemistry developed toward the beginning of the twentieth century, the usage of herbal medicines decreased. Therefore, when synthetic pharmaceuticals lost their efficacy owing to high levels of resistance as well as increased toxicity and expense, there has been a revival of interest in plant-based medicines in more recent years. More than half of all synthetic medications now in use are thought to be originated from plants [79].

4 Clinical Practice of African Traditional Medicine

Clinical practices are the terms used to describe therapeutic, educational, promotional, and rehabilitative services in African traditional medicine. The process of assessing a person's medical conditions and treating them is also referred to as clinical practise. These traditional healthcare services are delivered via tradition and culture as dictated by a certain philosophy, in which the norms and taboos within are closely observed and serve as the foundation for traditional health practitioners' acceptance in the communities they serve [80].

According to WHO health is "a condition of total physical, mental and social well-being and not only the absence of sickness or infirmity" [61, 81] and believes that everyone has the right to be healthy as a basic human right. The term "health triangle" refers to the interrelationship between one's physical, mental/emotional, and social well-being. Every civilization in traditional Africa had to come up with ways to solve its problems due to the identification of sickness and diseases. Around the world, several communities have unique medicinal herbs and is developed in a considerable amount of period. African traditional communities used herbal medicine, surgery and nutritional treatment like contemporary Western treatment practices [82].

These medicinal advancements were made long before the arrival of the Europeans. Treatment successes recorded were codified, and occasionally the right preparation and dosage techniques were prescribed. The contents and method of preparation varied according to the illness but were also influenced by other variables including geography, sociology, and economics. The important thing to note, however, was that patients were often healed of their physical or psychological

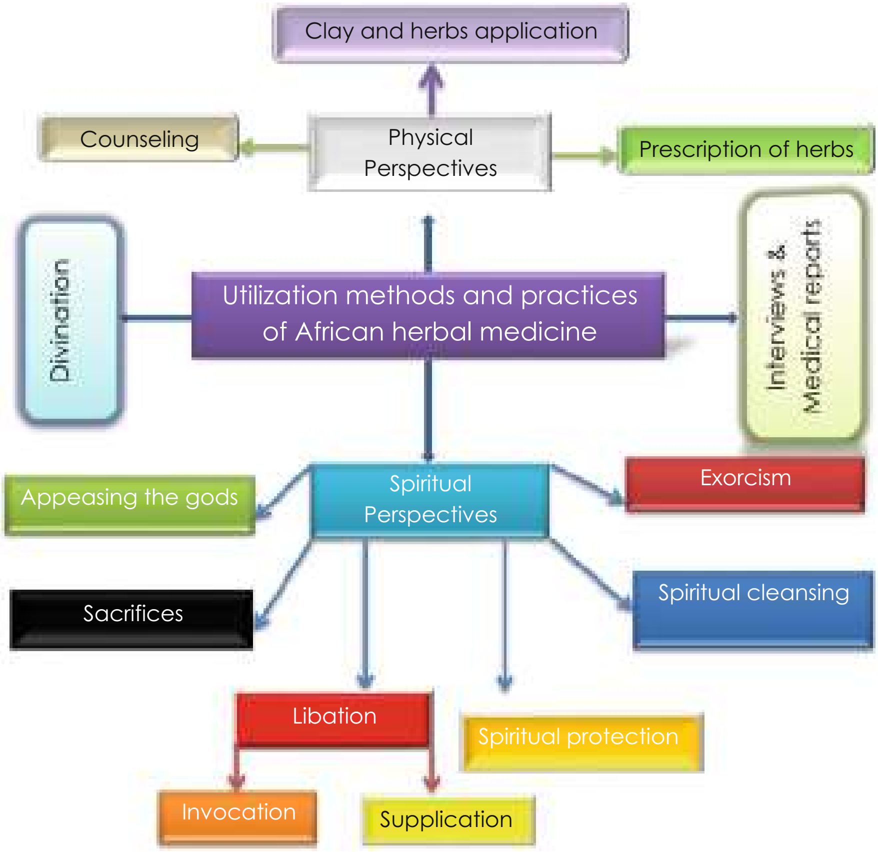

Fig. 2 Utilization methods and practices of African herbal medicine

diseases [83]. Traditional health practitioners (THPs) in African traditional medicine evaluate patients using the following approaches, as indicated in Fig. 2, in order to diagnose, cure, and prevent illness.

4.1 Divination

Divination entails communicating with the divine beings. It is a process through which information about a person or situation of disease is gained through the use of symbolism that is randomly placed to learn about curing diseases. It's also seen as a means of getting knowledge that is beyond human comprehension. Divination is a method in which seers get information by talking to spiritual entities including deities, ghosts, and ancestors [84]. Therefore, it is a crucial component in the traditional African method of illness diagnosis. Communicating with the non-human world is done while trying to establish the reason why the ailment or whether the sick person broke a rule. The bulk of the artifacts are divining bones, including bones from lions, hyenas, anteaters, baboons, crocodiles, wild pigs, goats, antelopes, etc. The bones stand for all the factors that may affect a person everywhere, regardless of their culture [85]. Divination is often the initial step in African traditional medicine and therapy because of its enlightening abilities [86].

4.2 Interviews and Medical Reports

Some traditional healers may do oral interviews to learn more about the patient's medical history, treatment history, and length of time in that condition. They are able to address the situation thanks to this method. In cases when a patient is unable to express their own wishes, the healer may ask a member of the patient's family to do so on their behalf. After the healing process is complete in the contemporary period, customers or patients are also encouraged to have medical diagnosis to make sure they are indeed recovered. The medical reports are often used as documentation for future reference and as a means of reassuring potential customers of their expertise and integrity. Because of the comprehensive approach used by the healers, no artificial boundaries are imposed between the healing process's natural and spiritual components [87]. Thus, the spiritual and physical spheres of health are seen from two key angles.

4.3 Spiritual Perspective

Cases with a spiritual component are treated as follows:

(i) Spiritual protection: If it is believed that an assault by bad spirits is the root of the illness, the individual will be safeguarded using amulet and talisman especially making craft bodies and spiritual bath to ward off the negative spirits. The rituals are intended to drive away bad and hazardous forces, spirits, or elements in order to get rid of any risks or evils that may have affected a family or society [88].

(ii) Sacrifices: Sometimes sacrifices are necessary to appease the spirits, gods, and ancestors. Animals like dogs and cats are occasionally sacrificed or buried alive at midnight to protect the soul of a dying person on the belief that their spirits are strong enough to replace life [84]. The fact that they are domesticated and raised among people raises the possibility that they might risk their own lives to protect their human family. This is particularly true in cases when the animal passes away mysteriously, leading people to assume that it gave up its life in exchange for that of its owner. Sometimes rituals are carried out to consecrate certain plants since they are essential to the healing process. Before, during, and after the manufacture and administration of medication, divine and ancestor sanctions are thought to be essential [89].

(iii) Spiritual purification: A sick person may be obliged to take a bath (water or animal blood) at particular times for a set period of time. Some communities in Ghana regularly engage in this activity [88].

(iv) Please the gods: If an illness is believed to be brought on by casting a curse or breaking taboos to please the gods or ancestors depending on how serious the situation is. A person is often expected to give certain objects for sacrifice and/or libation, including immaculate animals (doves, cats, dogs, goats, and birds), local gin, cola nuts, eggs, and plain white, red, or black fabric. Usually, the gods specify these things. Depending on the nature and severity of the situation, the used things may be dumped into the river, let to decay, or put at strategic locations, often at crossroads on the outside of the village [90].

(v) Exorcism is the practice of driving out evil spirits. Many traditional tribes have the view that bad spirits are mostly to blame for illnesses, particularly mental illnesses. Only a priest or other religious leader with the necessary credentials and authority may execute exorcisms. Sometimes the devil was represented with a wax or clay figure, which was finally destroyed. Exorcisms often include whipping the person or touching them with unusual items like animal tails and other objects to frighten the ghost away. They may also involve singing and dancing to the rhythm of drums. The person who is possessed will get a little upset before eventually calming down after the spirit has been expelled from the body. This practice is also performed for those who are mentally challenged. They believe that the possessed individual will not achieve freedom until they are released from the influence of the evil spirit. Exorcism is thus seen to be essential [91].

(vi) Libation: In a libation, liquid – typically local gin – is poured over the ground or other inanimate objects, and then words are chanted or recited over it. It is often considered a kind of prayer. Historically, beer was the only alcoholic beverage available, but wine, whisky, schnapps, and gin have all joined the mix in recent decades. Corn flour combined with water is a common alternative in certain countries, while in others people drink coconut water or make wine from palm fruit [92]. Some forms of libation pouring include an invocation, a prayer, and a final conclusion.

- **Invocation:** They begin by calling upon the ancestors, the soil, and the supreme God. Pouring libations is a manner of showing respect to the dead and appeasing the spirits, as believed by those who partake in the practice.
- **Supplication:** After invocation, supplication asks the spirits, gods, or ancestors to help the worshippers obtain spiritual consecration (cleaning) for themselves or their society due to transgressions like breaking taboos (s). The specifics of what is prayed for vary according to the circumstances [92].
- **At the end:** After the libation pouring, they express gratitude by calling upon spirits and ancestors. They end up cursing their enemies for wishing them harm, which suggests that praying for the success of one's adversary is a waste of time. In turn, their enemies, witches, and bad-skilled opponents

will all die [17]. In this procedure, the individual delivering the prayers would pour the drink into the ground and the witnesses would then respond to each prayer point.

4.4 Physical Perspectives

The following strategies are used if the sickness is physical in nature:

(a) Herbs are administered to the sick individual in accordance with the nature of their ailment. Each prescription comes with detailed instructions on the dosage, timing, and how to prepare the herb.
(b) Application of clay and herbs: Some therapeutic processes may benefit from the application of clay and plants. It is also sometimes employed in ceremonies to ward off the bad spirits that cause disease, along with certain particular plants and clay.
(c) Counseling: The sick person is occasionally advised on the dos and don'ts of treatment, the foods to eat or avoid, and to generally behave well in accordance with established social and cultural norms. If this is not done, the good spirits will withdraw their blessings and protection, which will leave the sick person vulnerable to illness, death, drought, and other misfortunes. When a taboo has been broken, this is often done [93].

In addition to offering effective and affordable treatments for the common illnesses that plague populations in the African region (such as malaria, stomach infections, respiratory issues, rheumatism, mental health issues, bone fractures, infertility, complications of childbirth, etc.), THPs also provide counseling, advice, and solutions to prevent future recurrence.

5 Unusual Aspects of the Use of Traditional Herbal Remedies in a Few African Nations

The physical world around us, including the cattle, trees, people, and towns, as well as the invisible, supernatural world of spirits, powers, and sicknesses, may all be understood in an African manner, just as there is an African way of comprehending God [94, 95]. Over the course of centuries, people created distinctive indigenous healing practices that were tailored to and characterized by their culture, beliefs, and environment [61]. These practices met the health requirements of their communities.

Different ethnic groups and cultures have created various healthcare systems and therapeutic approaches in order to address the many diseases, symptoms, and causes that they are aware of. Despite differences, there are significant parallels between how traditional medicine is practiced in many African nations. The World Health Organization (WHO) has encouraged the development of national policy and regulations as crucial indicators of the degree to which traditional medicine and complementary and alternative medicine are integrated within a country's national healthcare system in response to the growing popularity of these practices. The following is a description of several nations' unusual customs:

5.1 Ghana

Herbal medicine in Ghana is often used as the number one line of defense against disease, particularly in rural regions. Traditional healers are often used for a variety of reasons, including the challenge of inability to get access to healthcare institutions, inadequate infrastructures, and the cost of care. In addition, the patient to doctor ratio for conventional healers is 1:200 as opposed to the approximately 1: 20000 ratio for medical practitioners. This has a significant impact on how healthcare decisions are made. The choice of kind of healthcare is also influenced by other variables, including financial position, educational level, and recommendations from friends and family [96]. Traditional medicine has been practiced in Ghana for centuries. Most households have a basic familiarity with traditional medicine, which has been passed down through the generations through folklore, although this knowledge is usually held by spiritual healers**.**

Modern science-based medicine is widely accepted in Ghana, although traditional medicine is still highly regarded. They consider both the spiritual and physical sides of recovery. Herbal spiritualists, also known as "bokomowo," are widespread across the nation and engage in occult rituals, divinations, and prayers.

Traditional healers and practitioners in several Ghanaian groups, particularly in the Akan tribes, believe that breaking taboos may cause serious sickness in the offender(s) or community [97]. In the traditional religion of Africa, taboos play a significant role. A community or a group of people forbids them from doing or living certain ways.

The Ministry of Health of Ghana has established a Traditional Medical Directorate with the goal of creating a comprehensive, distinguishable, and standardized supplementary health system based on traditional and alternative medicine expertise. The current situation in Ghana involves the construction of institutions to combine scientific research into plant medicines with the inclusion of traditional medicine in university curricula [98]. Additionally, conventional medical colleges that provide degrees now prepare and certify herbal physicians.

5.2 Zambia

In Zambia, the number one rule is prognosis and using intricate therapeutic methods involving bush-based plants, several ceremonies, and the ultimate goal of curing sickness. Serious or persistent diseases call for "chizimba," which refers to permanently locking a sickness or illness away. To do this, a lizard must be killed, and its heart must be burned with charcoal and the roots of certain trees.

The mixture is applied to tiny wounds made on the affected region and left breast. You may utilize one plant alone or combine it with additional plants. The plant components are freshly collected, ground up, and allowed to dry before being immerged in H_2O or other solvents, such as alcohol. Major plant resources are utilized in powder form or burned to make charcoal. The majority of Zambia's 72 or so ethnic groups share 6 basic types of therapy: drinking, eating, drinking as porridge, making small wounds in the skin and applying, bathing with herbs, dancing to expel spirits, and steaming with boiling herbs. Nga:nga is the name of the traditional healer in Zambia [99].

5.3 Tanzania

Traditional medicine has been practiced separately from allopathic medicine in Tanzania since the time of the colonial period, but it is now in danger due to a lack of documentation, the loss of biodiversity in some areas as a result of resource discovery and excessive mining, climate change, urbanization, and agricultural modernization. Rural and urban dwellers in Tanzania utilize traditional medicine to treat both acute and chronic illnesses. There are four major categories of traditional healers: bone setters, herbalists, traditional birth attendants, and diviners. Indigenous medical knowledge began to disappear as the majority of traditional healers aged and died, the young people who were supposed to carry on the tradition shied away from it, and those in remote regions died of AIDS. Lack of information about highly threatened or endangered medicinal plant species in Tanzania was another barrier to the growth of traditional medicine [100]. The Ministry of Health now oversees the practice of traditional medicine. By raising knowledge of the value of traditional medicine and medicinal plants in healthcare and educating traditional health practitioners on best practises, conservation, and sustainable harvesting, efforts are being made to expand the use of traditional medicine [101].

5.4 South Africa

In South Africa, traditional medicine is a daily part of thousands of people who live therein. Actually, the usage of traditional medicines, often known as muti, is reported to be at 80% of the population. The term "muti," which is derived from the phrase "medicinal plant," designates drugs that are traditionally obtained from plants, minerals, and animals.

Traditional healers of the southern Bantu group are called Sangoma or Inyanga, and they are the keepers of healing power. Depending on the patient's condition, a female traditional practitioner may use one of many treatment modalities during a normal session. Antibiotics and immune system boosters are used to treat disease and weakness, while sedatives are used to treat depression, medications that induce vomiting are used to cleanse the digestive system, and bitter tonics are used to stimulate appetite. Before giving them the proper herbal remedies, she often gave them advice [102].

5.5 Kenya

Kenya, like many other nations in Sub-Saharan Africa, is struggling with a lack of health workers, especially in rural regions. According to anecdotal data, at least 80% of the rural dwellers are poor and only have access to traditional medical practitioners (TMPs) [19].

There is relatively little quantitative research or literature on traditional medicine, alternative healing methods, the demand for traditional medical practitioners, or the function that they play in delivering specific healthcare services to the rural poor in Kenya. TMPs are thus now underrepresented in HRH planning processes because of a lack of official government recognition, and their operations are still uncontrolled. Hospitals are chosen if they are accessible and economical, according to data gathered from the community [103].

In Kenya, alternative medicine practitioners are know as allopathic physicians by a large margin. They follow the same customs as other African nations. They often mix contemporary and natural medications, particularly if they have chronic illnesses like HIV/AIDS, high blood pressure, cancer, or diabetes [104].

5.6 Nigeria

Apart from their Western equivalents, who practice like other tribes, Nigeria's distinct ethnic groupings have separate medical professionals. They are referred to as “babalawos” by the Yoruba, “dibia” by the Igbo, and “boka” by the Northerners or Hausas [105]. People's lives have been touched by traditional and herbal treatments, particularly in rural regions where access to mainstream medicine is limited [105]. The high cost of Western treatment makes traditional medicine appealing, in addition to the challenge of proper approach and the concern of adultrated or phoney medications. Most modern herbalists and naturopaths are well-versed in the healing qualities of plants and the social construction of illness. They use this information in conjunction with state-of-the-art skills and procedures learned at any of the various schools dedicated to either herbal medicine or homoeopathy, which allows them to effectively treat and prevent illness. A list of Nigerian medicinal plants and their therapeutic benefits has been released by the Association for Scientific, Identification, Conservation and Utilization of Medicinal Plants of Nigeria (ASICUMPON) [65]. Information from other books has also been valuable [62, 68]. Lack of sufficient standardization and safety rules is still Nigeria's biggest issue with herbal medication [106]. However, the attention and participation of educated and scientifically oriented individuals in the practice of herbal medicine have greatly reduced the mystique and enhanced the acceptance of these treatments by a broader proportion of the population than might otherwise be suspicious.

6 Adverse Effects of Herbal Medicines

Herbal medicines are widely utilized because of their purported benefits, but they are not risk-free. Even while there is evidence that shows medicinal herbs may be beneficial, they can also have unintended consequences if used improperly or in excess. The likelihood of unintended outcomes rises when consumption is indiscriminate, careless, or uncontrolled, and when adequate standards are absent. These topics have been the subject of several international symposia on the study of medicinal plants [107]. Many African plants are poisonous, yet some of the continent's flora also has promising therapeutic applications [79].

In Nigeria, researchers observed that many people use herbal medicine despite the fact that many of them are uninformed of the potential toxicity of these medicines [74]. Unfortunately, several all-natural remedies have been linked to potentially fatal adverse effects [108].

The current measures are inadequate in negative effects monitoring of herbal medicine [61, 109]. Because of their all-natural and biodegradable makeup, herbal medications are often seen as being just as safe as their synthetic counterparts. A very small number of patients that make use of herbs and their supplements relate that information to their physicians. Many adverse pharmaceutical reactions may not be formally disclosed to various health regulatory authorities or organizations, since no pharmacovigilance studies are being undertaken and patients are not revealing information to health services. Poisoning from herbs may be difficult to diagnose. When damage is thought to have been caused by a herbal remedy, a conclusive prognosis might be challenging to draw an inference without a complete study of the herbal formulations and its components [110].

When taken in conjunction with conventional treatments, herbal remedies have a very low rate of negative effects [61]. Several investigations have shown that reported adverse drug reactions may frequently be attributed to incorrect preparation and usage of herbal therapies. It was discovered that liver issues were the most significant indicators of toxicity as a consequence of prolonged usage, which was shown in a study of WHO [61].

These plants' poisonous ingredients, such as saponin, tannins, alkaloid, oxalates, etc., are probably to blame for the toxicities that have been documented. Microbial infection as a result of unsanitary circumstances during preparation is another significant cause of toxicity in herbal medicines that is worth highlighting [111]. When herbal medications are used with certain conventional pharmaceuticals or supplements, toxicity may also emerge from a herb–drug interaction [57]. Toxic effects from misusing and misidentifying plants are also possible.

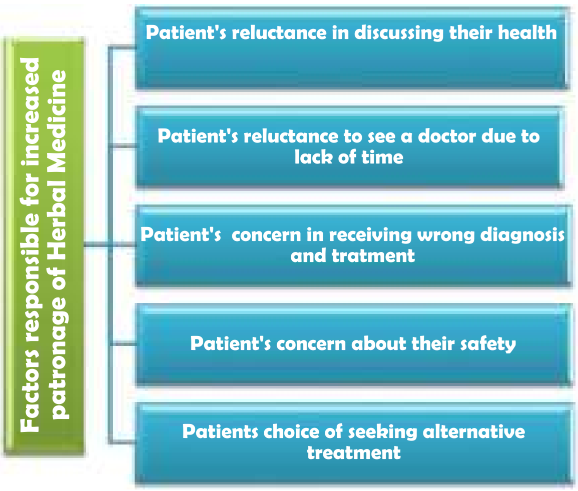
Therefore, it is important to convey accurate information of developing risk result as a crucial component of pharmacovigilance, which might really enhance patients' health and safety. This necessitates more coordination between conventional and contemporary medical professionals and pharmaceutical regulatory agencies. If known, the response time interval of a medicine and the incidence of an negative response may aid in determining the causative relationship in the management of pharmacovigilance [79]. Such details may be very helpful in interpreting medication safety signals and making judgments about further precautionary measures to be implemented in relation to future usage.

7 Factors Responsible for Increased Patronage and Self-Medication with Herbal Medicine

Many people believe that the various substances in herbal remedies work together synergistically, but this is not always the case. Herbal therapies are mainly made up of fragments of plants or unpurified plant extracts. The recent spike in public interest in herbal remedies has been attributed to a number of factors, including varying assertions about the efficacy or effectiveness of plant medicines. Unhappiness with the outcomes of synthetic drugs hoping that traditional remedies may bring about useful treatment of various ailments for which synthetic therapy with drugs proved unsuccessful or insufficient; reasons for this include (i) consumer preference for natural therapies and an increased interest in alternative medicines; (ii) an unshakeable conviction that herbal products are superior to manufactured products; and (iii) the high cost and unpleasant side effects of most conventional therapies.

There are a number of factors that contribute to patients and individuals turning to herbal remedies for treatment on their own (see Fig. 3), including (i) patients' reluctance to discuss their medical issues and concerns about the privacy of their health information, (ii) patients' reluctance to see a doctor due to a lack of time or (iii) patients' concerns about the possibility of receiving the wrong diagnosis and treatment due to vague or nonspecific symptoms, and (iv) patients' concerns about the safety of trying (v) patients' right to pick their own physician is inspiring them to try out alternative treatments like herbal remedies, with many making their decisions based on hearsay such "it helped a friend of mine" [112]. Furthermore, due to the

Fig. 3 Factors responsible for increased patronage of herbal medicine



influence of religion and the development in spiritual awareness [113, 114], many individuals are becoming more inclined to accept the therapeutic effectiveness of a course of treatment that is led by faith or intuition rather than by scientific logic.

When the body's innate capacity for healing is highlighted, the allure of herbal therapies increases [112]. These items have been significantly projected into larger spotlight by numerous herbal medicine producers' and their sales representatives' marketing tactics and efforts in addition to all of the aforementioned elements. Numerous media advertisement, especially those on television and radio, have greatly raised consumer awareness and given herbal goods an excessive amount of legitimacy and credibility [112, 115]. To appeal to the many age groups prevalent in the society, these advertisements are thoughtfully prepared. Herbal remedies are popular among the young because of the positive psychological benefits they have, the stress relief they provide, and the delay or prevention of the aging process. Herbs are recommended for their antiaging or rejuvenating benefits on the elderly, and for their fat-burning and beauty-enhancing properties in women [112].

8 Influence of Regulatory Policies on Safety of Herbal Medicines

It has been noted that the designation of many of these items as foods or dietary supplements in various countries is the primary cause of the majority of the issues related to the use of traditional and herbal medicines. As a result, before sale, no proof of the quality, effectiveness, or safety of these herbal medications is needed. In a similar vein, manufacturing standards and quality checks are often less stringent or monitored, and conventional healthcare providers may not always be qualified or certified. As a result, both national health authorities and the general public now have serious concerns about the safety of traditional and herbal medications [116]. Up until 2011, a customer in the UK may get a herbal product through one of three legal channels. The most prevalent method is the use of an unregistered herbal treatment, which is exempt from quality and safety requirements as well as consumer safety information [117]. The prepared tradional products must get license from the appropriate authorities before manufacturing can be tagged as "conventional" items or register as "traditional herbal medicinal products" [117, 118]. Similar to conventional medications, approved herbal medications are subject to quality, safety, and effectiveness standards. Therefore, for safe usage, they must be accompanied with detailed literatures which includes warnings, instructions, usage procedure, complications, storage instructions, and regulatory information. Typically, a booklet with this information is put inside the product packaging [117]. On the other hand, certain herbal medications cannot receive a license to market these items since there is inadequate proof of repeatable effectiveness to fulfil regulatory criteria [119].

In light of this, the UK established a "simplified registration procedure"for traditional herbal medicines known as the Traditional Herbal Medicines Registration Process. Herbal medicinal products sold under this system are expected to meet rigorous quality and safety standards, to recognize traditional uses as valid indications for their use, and to provide consumers with safety information in the form of a leaflet [117]. However, in different parts of the globe, particularly poorer nations, a wide variety of unregulated herbal products are sold without much in the way of oversight. The prevalent misconception that natural products are safe to use without risk of poisoning or adverse reactions may potentially lead to overexposure or even death. This misconception is not exclusive to underdeveloped countries. Even in advanced countries, people are drawn to "natural" products without fully understanding the risks associated with them, particularly with prolonged or excessive use [120].

9 Challenges of Monitoring Safety of Herbal Medicines

It is long overdue for both herbal products and pharmaceuticals to be included in pharmacovigilance systems, considering their widespread use. Since it is vital to evaluate the hazards connected with the use of herbal medicines primarily in terms of population exposure [121, 122], the efficacy and safety of the formulations has raised a cause for concern in public health. Protecting the public's health and promoting their safe use requires rigorous toxicity evaluation and vigilant pharmacovigilance [123]. This is because there has been a rise, in many regions of the globe, in the number of poisoning cases traced back to the use of herbal remedies. When laws concerning the use of traditional or herbal medicine are drafted and put into effect in different parts of the world, they often run into a number of problems. The regulatory status of traditional, complementary/alternative, and herbal medicines; the evaluation of their safety and efficacy; quality control; safety monitoring; and insufficient or poor knowledge about these medicines among national drug regulatory authorities are all problems faced and shared by many countries [122].

9.1 Challenges in the Regulatory Status of Herbal Medicines

Each country has its own criteria for classifying and defining herbal medicines. Depending on the rules controlling foods and medicines, the same medicinal plant may be categorized as a food, a functional food, a dietary supplement, or a herbal remedy in different countries. It also makes it hard to define the concept of herbal medicines for the purposes of national drug regulation [122], which may be confusing for patients and consumers. In the USA, natural products are regulated under the Dietary Supplement Health and Education Act (DSHEA) of 1994 [124].

A "dietary component" is a part of a product that is intended to be ingested as a dietary supplement. Vitamins, minerals, herbs, and other botanicals may be included in such products [124]. If a herb was on the market before 1994, the DSHEA may exclude it from further toxicity testing. In this scenario, the Food and Drug Administration (FDA) must provide evidence that a herbal medication or "dietary ingredient" poses a risk to human health. Another serious problem in many nations is that regulatory information on herbal drugs is frequently not exchanged between regulatory agencies and safety monitoring or pharmacovigilance centeres [121].

9.2 Challenges in the Assessment of Safety and Efficacy

It is an undeniable fact that there is a complexity of the requirements, research procedures, standards, and methodologies needed to assess the safety and effectiveness of herbal medicines in comparison to orthodox or conventional pharmaceuticals [122, 123]. Only one traditional remedy/plant part may include different hundreds of active ingredients, a combination traditional remedy may have many more of that amount. The amount of time and resources needed would be enormous if each active component in each plant used to design or create a herbal medication had to be separated. When a herbal product is a blend of two or more plants, such analysis may virtually be impossible [122].

9.3 Challenges in Quality Control of Herbal Medicines

The quality of the raw components used in their production has a significant impact on the safety and efficacy of these herbal medicines. Environmental variables and high-quality agriculture are all examples of extrinsic factors that influence source material quality in addition to intrinsic (genetic) features. Due to the complex interplay between these factors, it is difficult to perform quality controls on the herbal medicine raw materials [121, 122]. Species identification, proper storage, and material-specific sanitation and cleaning procedures are all vital for ensuring the quality of raw materials in the pharmaceutical industry. One of the most common challenges in ensuring the finished traditional herbal formulation quality, particularly the combination of traditional medicines, is validating the existence of all plants or starting components [122].

As a result, overall requirements and processes for quality control of final herbal products continue to be much more challenging [121, 122, 125] compared to those of conventional medications. In countries where herbal medicines are regulated, the WHO continues to support the development of quality assurance and control measures like national quality specifications and standards for herbal materials, Good Manufacturing Practices (GMP) for herbal medicines, labeling, and licensing schemes for manufacturing, import, and marketing [121].

9.4 Challenges in Safety Monitoring of Herbal Medicines

Increased use of herbal products in developed countries, reliance on plants by many in developing countries as a primary source of medicine, lack of regulation of herbal medicines in most countries, and the occurrence of high-profile adverse events have all contributed to a heightened awareness of the need to monitor safety and increase understanding of the potential harmful and beneficial effects associated with the use of herbal products in recent years.

Accidental ingestion of the wrong plant species, herbal products adulterated with other, unregistered medicines, contamination with toxic or hazardous substances, overdosing, misuse of herbal medications by consumers or healthcare professionals, and the concurrent use of herbal medications with other medications are all potential causes of negative outcomes following ingestion of herbal medicines. It is far more challenging to analyze adverse events connected with the use of herbal remedies than it is with conventional pharmaceuticals [122, 123], despite the growing interest among consumers, regulatory authorities, and healthcare professionals in doing so. Also, it is known that determining safety is complicated by factors such as the source of the plant, the variety of processing techniques used, the route of administration, and the possibility of drug interactions [126].

Identifying and gathering medicinal plants used in herbal therapies might be difficult since most herbal medicine manufacturers lack an expertise of taxonomy, botany, and documentation [127]. In order to eliminate the confusion caused by the common names, it is crucial to adopt the most generally used binomial names (including their binomial synonyms) for medicinal plants. For instance, the narcotic component included in *Artemisia absinthium* L., which goes by at least 11 different common names, has the potential to disrupt the central nervous system and lead to general mental impairment. Seven of the names used in common do not correspond to their botanical counterparts. *Valeriana officinalis* (garden heliotrope), which contains valepotriates with hypnotic and muscle relaxing effects, and *Heliotropium europaeum* (heliotrope), which contains potent hepatotoxic pyrrolidine alkaloids, are commonly mistaken with one another due to the popularity of common names. When reporting adverse drug reactions to herbal drugs, it is critical to provide the full scientific name of the plant, the component of the plant that was used, and the manufacturer's name. Therefore, the success of herbal medication safety monitoring relies on effective collaboration between botanists, phytochemists, pharmacologists, and other relevant players.

10 Importance of Traditional Medicine for Indigenous Peoples and Local Communities

Besides its obvious value in healing, traditional medicine also serves as a major economic driver in many regions. Traditional medicine, which must be emphasized, may have a significant role in shaping the character of a certain group. Pre-industrial tribes still participate in wild collecting, domesticating, cultivating, and managing medicinal plant resources since they are the ones who first identified most of the plants being used today [128]. Numerous indigenous peoples and local communities are helped by this economic activity, which in turn encourages the preservation of TM. While some therapeutic plants are grown for commercial purposes, the majority are still gathered from the wild [129].

Indigenous people and local groups may be knowledgeable about medical uses of plants as well as how to prepare and gather them. The indigenous people and local groups that have traditionally utilized herbal remedies may benefit greatly from this knowledge, as can anybody attempting to export and use medicine outside of its natural setting. TMK could also influence a society's spirituality and way of life. Traditional African medicine, for instance, is distinguished by a holistic worldview that sees all living things as part of a single, interconnected whole from which they get their life energy [130]. The practice of spiritual healing, which is regarded to be mediated by supernatural or spiritual forces, may be part of traditional African medicine. For psychological counseling and medical care, the majority of Africans with HIV/AIDS rely on traditional healers and herbal remedies [131].

11 Future Prospective

The advances recorded in the utilization of herbal medicine in Africa is imminent. The economic prospect of the utilization practice is enormous. However, the process can be intensified by promoting industrial and government plans and funding especially applying the biotechnological approaches in medicinal plant cultivation and processing. Also establishment of a scientific training and retraining programmes of traditional healthcare professionals should be encouraged. The implementation of positive strategies or blueprints for proper standards and regulation of herbal medicine practice is highly recommended. There is need for collaborative efforts to culminate in the beneficial effects of the practice of herbal medicine in Africa to avoid reprimand attitudes and perception of herbal medicine practices. The conservation and sustainable methods of harvesting medicinal plants need to be given top priority for habitat preservation. Proper documentation of medicinal plant types, their ecology, and method of distribution as well as various traditional extraction techniques for the preservation of cultural practices should be given attention. A partnership of practitioners of herbal medicine with scientist and researchers should be reassuring for proper collaboration and safeguarding the intellectual property rights of the herbal medicine practitioners.

12 Conclusion

The use of herbal medicines involves integrating a number of therapeutic techniques from indigenous medical systems that may date back many generations. This integration frequently yields helpful instructions for the choice, preparation, and application of herbal formulations for the treatment, control, and management of a wide range of illnesses. The availability and accessibility, efficacy, safety, cost, and cultural compatibility are the most often cited benefits of using herbal remedies in Africa. In African traditional medicine, practitioners evaluate patients utilizing their knowledge of the following techniques: divination, interviews and medical reports, spiritual and physical perspectives in order to diagnose, cure, and prevent illnesses.

In Africa, there has long been use of herbal medicine via various means and customs. The usage of herbal medicines for basic healthcare needs is still on the rise in Africa despite the advancements in Western medicine.

Abstract

The Nigerian ecosystem is most varied and contains diverse biological resources and biodiversity. The ecosystem serves as a source of medicines, foods, and diverse natural products that form the basis of traditional medicine in Nigeria. The use of traditional/herbal medicine has been in existence since time immemorial, and its practices are diverse. Its peculiarity and use are principally a function of the ethnic community in which the herbal practice is performed. It is used based on the active photochemical contained in the plants and therefore is a major component of treatment processes in over 300 ethnic communities in the country. The practice of herbal medicine is faced with a major challenge of documentation and a lack of clinical evidence to justify its use in most rural areas. This has posed a serious problem in meeting a requirement for herbal medicine that is standard and can be adopted in clinical practice. The country is rich in a collection of plants that can be used for medicinal purposes and herbal treatments, and their efficacy has been reported by research. Plants such as moringa (*Moringa oleifera*), neem (*Azadirachta indica*), and guava (*Psidium guajava*) to mention a few have been reported and found to exhibit good microbial inhibition. It is important to report the richness of Nigerian herbal medicine and its efficacy in treatment activities which will serve as evidence to support the incorporation of this approach into clinical medicine procedures. A number of plants in Nigeria have also been reported to contain terpenes, glycosides, alkaloids, and polyphenols which have therapeutic potential. Compounds such as orosunol, alloeudesmenol, and hanocokinoside have been identified but are yet to be researched in Nigeria. This chapter tends to highlight the medicinal plants in Nigeria, their application and use, and various therapeutic activities they can perform. Conversely, there is a dire need for information and research into the use of herbal plants to cure neglected tropical diseases (NTDs) that can be facing humans in Nigeria. It also highlights the prospects and future trends in the use of herbal medicine in the quest for acquiring a basis for herbal medicine procedures to be incorporated into Nigerian clinical care.

1 Introduction

Herbal medicine is the process employed in the use of herbal plants to treat diseases thereby enhancing the health and well-being of humans [1]. The potency of herbal plants differs and must be taken with caution. The use of herbal medicine is crucial in the provision of healthcare to the populace in rural and most developing and underdeveloped countries. Its use is also adopted in some developed countries in the treatment of some ailments. Herbal medicine may provide healing for ailments, the welfare of the community, growth, and the creation of wealth for individuals. The World Health Organization [2] reported the issue of global health is a major concern, as infectious diseases have been reported to be a cause of threat to humans and have accounted for 61.7% (5.9 million) out of the 9.6 million deaths occurred in the sub-Saharan regions of Africa. The use of plants with medicinal values in health care has been used since the olden years. Studies have shown evidence of the efficacy of medicinal plants and have provided information on the plant-based compounds that have therapeutic uses [3]. Based on this, researchers are developing research tools that are modern to develop herbal medicine processes and paying the way for its adoption into modern medicine [4]. At the concoction dosage, herbal medicines of plant origin are generally regarded as safe (GRAS) and this is based on their usage [5]. Based on this, the natural and abundant source of active drugs are plants which are very useful in the ethno-medicinal cure of various ailments [6].

Herbal medicine has been seen as an integral part of traditional medicine with a wide range of characteristics and components recognized by the World Health Organization (WHO). Their practice cuts across various sectors such as health practices, Indigenous knowledge, beliefs, spiritual therapies, and techniques which may be carried out in unison or in combination to address issues relating to diseases, and diagnose or prevent all forms of illness. In developed countries, the concept of herbal medicine has evolved into contemporary medicine. The use of herbal medicine is defined by the beliefs, environment, and culture and how it satisfies the needs and health concerns of the locality [3]. The increased and widespread use of herbal medicine has promoted its integration into the national healthcare systems in some countries by World Health Organization. This will go a long way in the development of policy and regulations nationally and easy incorporation into the national healthcare policy of the country.

Herbal medicines basically refer to all herbs, herbal preparations, and materials, or finished products from herbal products that may contain active ingredients from parts of plants or materials. It is also called botanical medicines or phytomedicines. The materials from plants to be used are the roots, seeds, berries, flowers, or barks and are components of many drugs in conventional medicine. The dependence on herbal medicine for health issues is a major activity in over 80% of the population in Asian and African countries [3]. It was estimated by World Health Organization that about 70–80% of the population depends on alternative medicine in developed countries of the world; it is the most popular form of practice and very lucrative in the international market. The major issue is the irresponsible or unregulated use of these herbal products which are capable of increasing the risk of toxicity in humans. The effectiveness and safety of herbal medicine products and practices lack scientific evidence making it difficult to evaluate their performance [4]. Different reactions have been reported when used or used in combination with conventional medicines, and despite its international adoption, there is no international standard for its evaluation. Dearth in the knowledge of plant population and its use as medicines is a major threat to the sustainability of herbal plants.

In Nigeria, the application of herbal medicine is more pronounced in the grassroots areas as a measure of clinical care. It employs approaches that hover around the use of holistic natural healing methods, and the growth and wealth creation of the locality. Due to this, recent research is being geared towards developing a framework that can be adapted to modern health practices using modern research tools and equipment [7]. The practices of herbal medicine are endemic to every society as they have developed methods for approaching this practice. The concept of illness and health involves the individual and totality of being which covers the social, emotional, spiritual and physiological, and immediate environment. The system of traditional medicine in Nigeria encompasses the following: traditional systems – which have been practiced by several Nigerians over decades; folk systems – which focus on the culture, faith, and beliefs of people; Indigenous system – which involves the knowledge level and resources that belong to the local people; and communal system – which involves resources collectively owned. In Nigeria, there are over 300 ethnic groups that are diverse and the practice of herbal medicine differs across these localities [8].

The acceptance and use of Indigenous herbal medicine must first be located within the global and historical concept of the locality. Despite the existence of herbal medicine over the years, a conflict of interest in the knowledge and use of these herbal medicines exists. This occurred especially when the European cultures crept into our health system in the fifteenth century and it distorted the traditional herbal medicine system and the local practices while ensuring the objectives of the European cultures are met [3]. Herbal medicines can be used by adults, pregnant women, and even children, and it has been evaluated, but their use in the population without health issues is yet to be evaluated empirically. With the immeasurable importance of herbal medicine, its use may produce several negative effects such as rashes, allergic reactions, asthma, headaches, nausea, vomiting, and diarrhoea [1]. Its use must be prescribed by qualified and registered personnel. When herbs are used in combination with pharmaceutical medications, interactions based on their activities may occur. Based on this, it is important to inform medical doctors about the herbal mixture taken at that point of diagnosis. The issue of unregulated use of herbal plants and mixtures is of great concern as it may affect organs of the body when in excess. This review, therefore, describes herbal plants, their use, various properties of herbal plants, and future prospects of herbal plants in Nigeria due to the large number of plant species that have not been analyzed for phytochemical constituents.

1.1 Concept of Herbal Medicine

Herbal medicine as described by the World Health Organization involves the total skills, knowledge, and practices which is based on various theories, experiences, and Indigenous beliefs of different cultures and used in the prevention, treatment, diagnosis, or improvement of health, both physical and mental. Its practice is common in other African countries and Asia, and an interesting area of research is the polypharmacological formulation of extracts from plants for use in healthcare [7]. The screening of herbal plants based on their phytochemical constituents is done to ascertain their antimicrobial activities against a broad spectrum of microorganisms. The resistance activities by most bacteria have caused a serious problem [8] and have stimulated continuous research in this area for the development of therapeutic agents that are safe. Plants with important components and promising attributes in inhibiting microorganisms that cause diseases and their use in ethnomedicine have been documented [9]. Research activities are in place to understand the functioning of herbal plants, and these results have formed a prototype for about 25–30% of marketed drugs [10].

1.2 Herbs, Traditional Knowledge, and Concept of Health in Nigeria

The health and well-being of individuals in every society differ as a result of various developmental approaches, knowledge, and practices. In most cultures of the world, the concept of good health and the condition of illness involve the physical, emotional, social, spiritual, and psychological well-being within its environment [8]. Herbal medicine in Nigeria has its roots in the traditional, folk, communal, and Indigenous systems thereby forming a link with culture, faith, and beliefs which has evolved over the years and is at the centre of the national economy [9]. The concept of herbal medicine is based on different experiences, beliefs, sociocultural diversity, and diverse ethnic groups [10], and this has limited the development of uniform herbal medicine practices.

WHO [11] described herbal/traditional medicine as "the totality of skills, knowledge, and practices that is based on belief, theories, and experiences which are endemic to different cultures." Herbal medicine is used in maintenance, prevention, improvement, diagnosis or treatment of illness, both mental and physical [12]. Based on this, it can be said that historic experiences dictate the form and contents of herbal medicine to be used for disease treatment and it is within a social and ecological context. Over the years, the perception of Nigerian herbal medicine usage has persisted among educated Nigerians most especially in the medical profession [13]. Based on this, the Traditional Nigerian Medicine Practitioner (TNMP) is constantly involved in ceremonies that are targeted towards restoring individuals to social, spiritual, and psychological harmony [14]. Since the 1960s, the Nigerian research community and some other post-colonial states in the developing world realized the inherited healthcare system and health needs of the people [15]. After these conscious efforts in the development of herbal medicine, WHO reported an increasing global trend to include herbal medicine in healthcare systems in developed and developing countries to address chronic ailments which conventional medicine could not address [2]. This has provided a leeway for the government to explore ways of connecting Indigenous healing practices with the medical systems.

2 Phytochemical Components of Herbal Plants

Phytochemicals are bioactive organic compounds that are contained in herbal plants and have medicinal purposes. This phytochemical can function in defensive roles to fight against chronic diseases and genetic and infectious diseases. They are found in grains, fruits, vegetables, and other forms of products from plants [16–18]. They can perform activities that are metabolic in nature, functioning as primary metabolites in all plants such as fats and sugars, and secondary metabolites providing specialized functions, and are found in plants that are of small range. Secondary metabolites are described as the biomolecules produced from sustainability or adaptation processes by plants in their native environments. These result from factors such as pollination, predation, and protection from drought and are not required for survival by the plant [19]. These metabolites and pigments can be processed into various drugs because of their healing effects, such as examples listed in Table 1.

Herbal plants are screened that differ in bioactive compounds; some of the compounds are tannins, alkaloids, and saponins [25]. The functional classes of phytochemicals that have therapeutic potential in them are:

- Anticancer agents
- Antioxidants
- Detoxifying agents
- Immunity-potentiating agents
- Neuropharmacological agents [19]

Table 1 Plants and the secondary metabolite they contain

S/N	Secondary metabolites	Plant source	Botanical names	References
1	Quinine	Cinchona plant	*Cinchona officinalis*	[20]
2	Digoxin	Foxglove plant	*Digitalis purpurea*	
3	Codeine and morphine	Poppy plant	*Papaver somniferum*	
4	Inulin	Dahlias plant	*Dahlia pinnata*	
5	Phytoalexins	Orchids	*Orchis militaris*	[21]
6	Teroenoids and steroids	Orchid plant	*Orchis militaris*	
7	Triterpenes and steroids	Foxglove plant	*Digitalis purpurea*	[22]
8	Stilbenoids and bibenzyls	Orchid plants	*Dendrobium chrysotoxum, Orchis militaris*	
9	Phenantherens	Orchids	*Gymadenia conopsea, Bletilla striata, Dendrobium moniliforme,* and *Cypripedium macranthos*	
10	Alkaloids	Orchids belonging to the genus *Dendrobium*	*Dendrobium nbile, D. chrysanthum, D. anosmum, D. crepidatum,* and *D. findlayanum*	[23]
11	Coumaris	Sweet woodruff and tonka bean	*Galium adorantum* and *DIpteryx odorata,* respectively	
12	Polyphenols	Ginger, guava, neem, and moringa	*Zingiber officinale, Psidium guajava, Azadirachta indica,* and *Moringa oleifera*	[23, 24]
13	Terenes	Moringa, guava, and neem ginger	*Moringa oleifera, Psidium guajava, Azadirachta indica,* and *Zingiber officinale*	
14	Glucosides	Guava, ginger, neem, and moringa	*Psidium guajava, Zingiber officinale, Azadirachta indica,* and *Moringa oleifera*	

Each functional class of phytochemical listed consists of various compounds which have multiple functions and varying levels of potency. Some plants can produce phytochemicals that have distinct functions and belong to the biochemical motifs [26]. Some of such bioactive compounds are listed in Table 2.

2.1 Phytochemical Screening of Medicinal Plants

In most plants used as medicines and aromatic plants, the major sources of active ingredients are found in the stems, barks, flowers, roots, or leaves [19]. The mode of action of these ingredients can be connected to the ecological or biochemical identities of plants and animals when functioning in the human central nervous

Table 2 Bioactive compounds with their distinct functions

S/N	Bioactive compound	Functions	References
1	Titerpenoids	Anti-inflammatory activity	[27]
2	Tannins	Anti-microbial, anti-inflammatory, and astringent properties	
3	Saponins	Blood cleansers, antibiotics, and expectorants	
4	Alkaloids	The effects are significant on the central nervous system (CNS)	
5	Glycosides	Increases the forces of systolic concentration	
6	Carotenoids	Anti-aging, antioxidant, anti-diabetic, anti-cancer, pro-vitamin, hepatoprotective properties, anti-obesity, and immune modulating	[28]
7	Phenolic compound	Antioxidants, attractants (carotenoids and flavonoids), structural polymers (lignin), defence response chemicals (phtyoalexins and tannina), and ultraviolet (UV) screens (flavonoids)	[29]
8	Terpenoids	Antioxidants, anti-cancer, anti-microbial, anti-inflammatory, and antallergic	[30]
9	Peptides	Anti-microbial, anti-cancer, antioxidative, anti-inflammatory, immunomodulatory, and anti-hypertensive	[31]
10	Fatty acids	Anti-cancer, anti-immune disorders, anti-vardiovacular diseases, and anti-osteoporosis	[32]
11	Terpens	Antioxidants, anti-cancer, antimicrobial, anti-inflammatory, food preservation, and antallergic	[30]

system [33]. The steps that are taken to adequately utilize the bioactive compounds from plants involve the following steps as described by [34]:

- Extraction
- Primary screening
- Isolation
- Purification
- Characterization
- Pharmacological and toxicological analyses

The principle of pharmaceutical extraction involves the division of microorganism tissues and plant constituents with the aid of a buffer solution or solvent that is selective and carried out according to protocols that are standardized [35, 36]. The quality of extract from plants is influenced by the part (root, bark, or leaf) of the sample, the extraction method, and the solvent used and concentration during extraction. The chemical constituent effects depend on the type of plant material, the source of the plant, the processing extent, the moisture level, and the size of particles [37]. The composition and quality of secondary metabolites are influenced by factors such as the type and timing of phytochemical extraction, the concentration and nature of the solvent, the temperature of processing, and the analyses of polarity [37]. As reported by [34, 38, 39], purification, identification, and characterization of

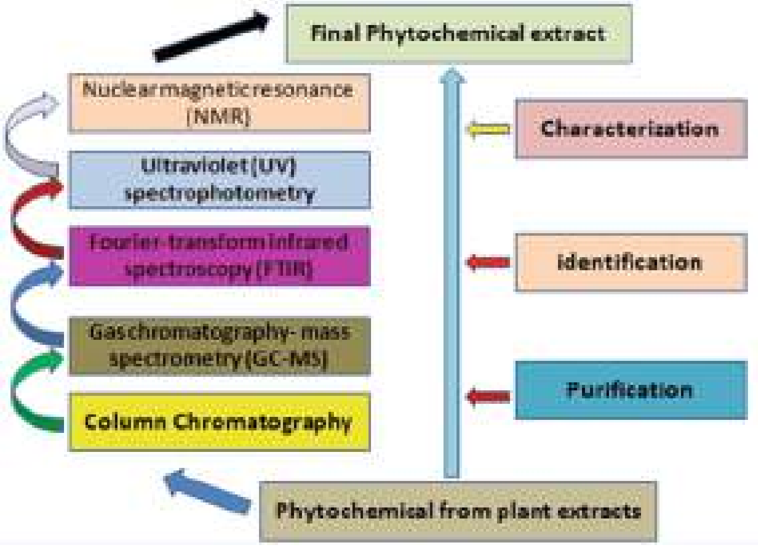

Fig. 1 Stepwise characterization of phytochemical groups. (Source: Refs. [34, 38])

phytochemicals from herbal extracts are carried out following the stepwise techniques of GC-MS (Gas Chromatography-Mass Spectrometry), FTIR (Fourier-transform infrared spectroscopy), UV (Ultraviolet), and finally NMR (Nuclear magnetic resonance) as illustrated in Fig. 1.

2.2 Processing Effects of Phytochemicals from Medicinal Plants

The antioxidant activities in herbal plant extracts can either increase or decrease as a result of the method of processing the herbal plants. Various methods can impact the availability of phytochemicals and their ability for use in pharmacology. An example is the sandpaper leaf (*Ficus exaperata*) which has the ability to inhibit arginase and angiotensin-1-converting enzymes (ACE). The best processing method is the soaking method, and it is far better than boiling, blending, and hand maceration [40]. The health benefits associated with herbal plants in mono or poly formulations result from a mixture of phytochemicals in a whole form and produce an overall action that may be due to the combined properties of antioxidants [36, 41]. The use of different processing methods, thermal or non-thermal, has been studied [42].

3 Medicinal Plants in Nigeria

Nigeria is blessed with diverse species of flora which may be used for medicinal purposes. Despite the discovery of antibiotics and their recorded successes, death caused by infectious diseases is ranked second in the world [43]. The quest for new

Table 3 Some Nigerian medicinal plants and their therapeutic functions

S/N	Plants with medicinal properties	Point of action	References
1	*Macaranga barteri* and *Ageratum conyzoides*	Antiviral	[45–48]
2	*Gossypium arboretum, Cajanus cajan, Heeria insignis, Momordica charantia,* and *Amaranthus spinosus*	Anti-parasitic	[49–52]
3	*Azadirachta indica, Justicia flava, Cassytha filiformis, Allamanda cathartica, Morinda lucida, Enantia chlorantha,* and *Landolphia owariensis*	Anti-parasitic, anti-fungal, and antibacterial	[50, 52–56]
4	*Ficus exasperate, Adansonia digitate, Cola nitida, Argemone mexicana, Annona senegalensis, Citrullus colocynthis,* and *Vernonia amygdalina*	Antibacterial	[50, 52, 56–59]
5	*Garcinia kola Buchholzia coriace*	Analgestic, antioxidant, anti-microbial, anti-inflammatory, anti-hypocholesterolemic, antiviral, and anti-diarrhoea	[60–62]
6	*Cola nitida and C. acuminata*	Anti-proliferative, anti-androgenic, and anti-coronary activities	[63, 64]
7	*Buchholzia coriacea*	Antioxidant, anti-microbial, and antitumor properties	[68, 69]
8	*Buchholzia coriacea*	Anti-allergies, anti-inflammation, platelet aggregation, free radicals, anti-ulcer, and hepatoxins potentials	
	Buchholzia coriacea	Anti-microbial, anti-diabetic, anti-helmintic, anti-ulcer, and anti-plasmodial activity	[65–67, 70–76]

compounds with therapeutic processes to treat diseases that are infectious has increased research in this area for the best plants that may contain massive drug compounds. Some of the herbal plants and their antimicrobial activities are presented in Table 3. The resistance by microbes to antibiotics has also stimulated the continuous research and need for a potent and safe therapeutic agent [44].

There have been several reports by researchers on plants that can be used for the treatment of ailments. Among the Esan in Edo state, 70 herbal plants were identified for the use of treating various sicknesses and ailments [77]. Among the Fulanis and Hausas, 72 plants were identified that can be used for treating cancer and disorders in Northern Nigeria [78]. In south-western Nigeria, about 73,143 individuals and 132 species of plants were identified as important in cancer treatment and management, diabetes, and haemorrhoids [79–81]. It was reported by Rufus [82] that the majority of tree species that grow in the Niger Delta have medicinal and pharmaceutical importance. Some plants used in Nigeria for herbal treatment and the specific ailments they addressed are presented in Table 4.

Plants regarded as weeds are very surprising to have phytochemicals that are useful for disease treatments and an important role in the fight against microorganisms [90]. Some weeds are consumed as drugs in orthodox medicine while some have been used locally for disease treatments [91, 92]. Most medicinal plants have become rare as a result of land clearing for structural development, and this may be a setback for the development of herbal medicine in Nigeria. The government can be blamed for its inefficient role in environment conservation issues and policy implementation around this. Another threat is the loss of culture which has made youths and younger generations to fill differently about herbal medicine. This is basically due to the recent development in technology and the rapid rate of urbanization. At this point, herbal medicine associations need to swing into action.

3.1 Antimicrobial Activities of Medicinal Plants

There are several activities herbal plants can address. The phytochemical in these plants can be extracted by using an aqueous solution, ethanol, dichloromethane, and methanol. The medium for extraction dictated the potency of the phytochemical and work rate [93]. Some antimicrobial activities addressed by different medicinal plants/extracts are highlighted:

- ***E. coli***

It can be addressed by the application of leaf and root extracts of *Terminalia glaucescens* [87, 94]. It is a gram-negative bacterium that can be addressed by the application of methanol extracts from medicinal plants [44]. The aqueous and ethanolic extracts of *Zingiber officinale* have shown multidrug resistance to food-borne pathogens. The methanol, water, chloroform, leaves, and petroleum ether extracts of *Senna alata* have antimicrobial properties at a concentration of 500 μg/mL and fight the bacteria isolates [95].

- ***S. typhi***

It can be addressed by the application of leaf and root extracts of *Terminalia glaucescens* [87, 94].

- ***Bacillus subtils***

The methanol extracts from some medicinal plants can fight against clinical isolates of these gram-positive bacteria. The methanol, water, chloroform, leaves, and petroleum ether extracts of *Senna alata* have antimicrobial properties at a concentration of 500 μg/mL and fight the bacteria isolates [95].

Table 4 Some Nigerian medicinal plants, parts, and their uses

S/N	Family	Scientific name	Habit	Part of plant used	Uses	References
1	Anacardinaceae	*Anacardium occidentale*	Tree	Fruits, stem, leaves, and bark	Treatment of malaria, typhoid fever	[81]
2	Asteraceae	*Tridax procumbens*	Herb	Leaves	For treatment of skin infections and sores on the skin	
3	Bignoniaceae	*Kigelia africana* Benth	Herb	The whole plant	Back ache and stomach ache	
4	Bombacaceae	*Bombax buonopozense*	Tree	Leaves and bark of stem	As blood tonic, for stomach ache, and skin infection treatments	
5	Caricacae	*Carica papaya*	Shrub	Stem bark, fruits, and leaves	Catarrh, cough, dysentery, malaria, diabetes, venereal diseases, and purgative	[80]
6	Cucurbitaceae	*Telfaria occidentalis*	Climber	Leaves	Treatment of convulsion and as a blood tonic	
7	Dioscoreaceae	*Dioscorea bulbifera*	Climber	Fruits	Treatment of fever and boils	
8	Dioscoreaceae	*D. dumentorum* (Kunth)	Climber	Tubers and leaves	Abdominal pains and malaria treatment	
9	Euphorbiaceae	*Euphorbia heterophylla*	Herb	Roots and leaves	Treatment of skin infections and as a purgative	
10	Euphorbiaceae	*Jatropha curcas*	Shrub	Leaves	Treatment of haemorrhoids	[79]
11	Fabaceae (Papilionioideae)	*Baphia nitida*	Small tree	Roots, bark, and leaves	Treatment of small pox, diabetes, constipation, and skin disease	
12	Fabaceae (Papilionioideae)	*Centrosema pubescens*	Climber	Leaves	Treatment of diseases occurring on the skin	
13	Guttiferae	*Garcinia kola*	Tree	Stem bark, foots, and fruits	Treatment of diabetes, cough, tooth ache, anti-cancer, and dysentery	
14	Icacinaceae	*Icacina trichanta*	Shrub	Roots and leaves	As a purgative, toothache, abortificient, aphrodisiac, and rheumatism	

15	Lilaceae	*Allium ascolanicum*		Whole plant	Treatment of dysentery, diabetes, anti-cancer, and haemorrhoids	[83]
16	Menispermaceae	*Rhigiocarya racemifera*	Climbing plant	Leaves and seeds	As an aphrodisiac and sedative	[78]
17	Moraceae	*Milicia excelsa*	Tree	Leaves, roots, and bark	For insomnia, malaria, nausea, and abdominal pain	
18	Olacaceae	*Olax subscorpioidea*	Tree	Twigs, bark, leaves, roots, and stem	Treatment of venereal diseases, guinea worm, yellow fever, and jaundice	[84]
19	Rutaceae	*Citrus aurantifolia*	Tree	Bark, roots, and stem	Gonorrhoea, diabetes, and haemorrhoids	[85]
20	Zingiberacea	*Aframomum melegueta*	Herb	Leaves and seeds	Stimulants and haemorrhoids	
21	Sapindaceae	*Paullinia pinnata*	Woody climber	Seeds, roots, and leaves	Leprosy, dysentery, jaundice, and dysentery	[79]
22	Solanaceae	*Nicotiana tabacum*	Shrub	Leaves	A stimulant, convulsion	
23	Steruliaceae	*Theobroma cacao*	Tree	Roots, seeds	Stimulant, toothache, and gingivitis	
24	Tiliaceae	*Corchorus olitorius*	Woody herb	Seeds, roots, and leaves	Fever, asthma, and diarrhoea	
25	Polygalaceae	*Carpolobia lutea*	Shrub	Bark, leaves	Aphrodisiac	
26	Annonaceae	*Annona senegalensis*	Tree	Leaves, fruits, and roots	Treatment of toothache, cancer, and various venereal diseases	[40]
27		*Monodora myristica*	Tree	The seeds	Treatment of headache, constipation, anaemia, and arthritis	
28		*Uvaria barteri*		The leaves	Toothache	
29		*Enantia chlorantha*	Tree	Tree bark	For treatment of jaundice and fever	
30	Apocynaceae	*Picralima nitida*	Shrubs		Treatment of dysentery, fever, and diabetes	[86]

(continued)

Table 4 (continued)

S/N	Family	Scientific name	Habit	Part of plant used	Uses	References
				The roots and tree bark		
31		*Alafia barteri*	Liana	The roots and leaves	Treatment of diabetes	
32		*Funtumia elastic*	Tree	The latex and stem	Treatment of jaundice and pile	
33		*Holarrhena floribunda*	Tree	The leaves, bark, and the whole plant	Treatment of jaundice, gonorrhoea, dysentery, and anti-malaria	
34		*Alsotonia boonei*	The tree	The leaves and roots	Treatment of fever, diabetes, and haemorrhoids	
35		*Raicolfia vomitoria*	Thee	The leaf sap, bark, and root	Treatment of measles, jaundice, convulsion, herpes, and internal disorders in man	
36	Asclepiadaceae	*Pergularia daemia*	Climber	The whole plant	Treatment of pile, diabetes, and fever	[41]
37		*Gongronema latifolium*		The stem and roots	Treatment of haemorrhoids and anthelmintic	
38		*Calotropis procera*	Shrub	The latex, roots, bark, and leaves	Treatment of diarrhoea, cough, dysentery, elephantiasis, ringworm, leprosy, and diabetes	
39	Asteraceae	*Chromolaena odorata*	Herns	Leaves	Treatment of dysentery, headache, and antimicrobial	[46]
40		*Ageratum conyzoides*	Herb	The whole plants	Treatment of ulcer, diabetes, menstrual pain and irregular menstruation, and diarrhoea	
41	Bombacaceae	*Adansonia digitata*	Tree	The bark, pulp, leaves, and fruits	Treatment of diabetes, malaria, and asthma	[87]
42		*Ceiba pentandra*	Tree	The oil and leaves	Treatment of sores, laxative, and rheumatism	
43	Moraceae	*Fisus sur*	Tree	Roots	Haemorrhoids	
44	Connaraceae	*Cnestis ferruginea*	Shrun	Roots and leaves	Treatment of fever, laxative, tooth ache, and haemorrhoids	
45		*Byrsocarpus coccineus*	Shrub	Roots and leaves	Treatment of cancer, jaundice, pile, dysentery, and haemorrhoids	

46	Concolvulaceae	*Merremia tridentate*	Climber	The whole plant	Treatment of gonorrhoea	
47	Cucurbitaceae	*Momordica charantia*	Climber	The fruit, leaves, and whole plant	Treatment of burns, ulcers, pile, diabetes, convulsion, and skin infections	[88]
48	Euphorbiaceae	*Alchornea laxiflora*	Shrub	The roots and leaves	For typhoid fever treatment and as antioxidant	
49		*Acalypha fimbriata*	Herb	Leaves	Treatment of asthma, ulcer, and rheumatism	
50		*Crton lobatus*	Herb	Roots and leaves	Rheumatism and skin diseases	
51	Fabaceae (Caesalpimioideae)	*Caesalpina bunduc*	Shrub	The roots, seeds, and leaves	Treatment of diabetes, fever, and anthelmintics	
52		*Albizia adianthifolia*	Tree	Bark of stem	Treatment of cough, gonorrhoea, night blindness, and haemorrhoids	
53	Fabaceae (Mimosoideae)	*Albizia zygla*	Tree	Bark and leaves	An astringent	[89]
54		*A. ferruginea*	Tree	The leaves, roots, and stem bark	Constipation and dysentery	
55	Fabaceae (Papilionooideae)	*Dalbergiella welwitschii*	Shrub	The leaves, roots, and stem	Menstrual order, diabetes, purgative, and anthelmintics	
56		*Ptrocarpus Osun*	Tree	Bark of the stem and root	Asthma, eczema, and infections on the skin	
57	Longaniaceae	*Anthoclesta djalonensis*	Tree	Stem bark and leaves	Abdominal pain, diabetes, eczema, and a purgative	
58	Marantaceae	*Thaumatococcus danielli*	Herb	Fruit	Treatment of diabetes	
59	Melastomataceae	*Heterotis rotundifolia*	Herb	The entire plant	Venereal diseases and antimicrobial	
60	Menispermaceae	*Rhigiocarya racemifera*	Climbing plant	Seeds and leaves	An aphrodisiac and sedative	

- ***Staphylococcus aureus***

The methanol extracts from some medicinal plants can fight against clinical isolates of these gram-positive bacteria.

- ***Pseudomonas aeruginosa***

It is a gram-negative bacterium that can be addressed by the application of methanol extracts from medicinal plants [44].

- ***Klebsiella pneumonia***

It is a gram-negative bacterium that can be addressed by the application of methanol extracts from medicinal plants [44].

- ***Salmonella typhi***

The tree bark of ethanol and acetone extracts of *Azadirachta indica* (*A. Juss*) has significant bacterial activity on the microbes at a concentration of 25–40 mg/mL [96]. The aqueous and ethanolic extracts of *Zingiber officinale* have shown multi-drug resistance to food-borne pathogens.

- ***Aspergillus niger***

The leaves of *Diospyros* spp. have the ability to resist this microbe [97].

- ***Proteus aeruginosa***

The methanol, water, chloroform, leaves, and petroleum ether extracts of *Senna alata* have antimicrobial properties at a concentration of 500 μg/mL and fight the bacteria isolates [95].

3.2 Anti-malarial Activities of Medicinal Plants

The incidence of malaria is a threat to global health and has killed millions of people worldwide in sub-Saharan Africa. Multi-resistant malaria parasites have become the order of the day, and this has resulted in the quest for developing combined formulations through research to address the parasite and develop a more efficient therapeutic drug [98]. Some of the combined drugs used are the artemether-lumefantrine and the sulfadoxine-pyrimethamine. *Allamanda cathartica* and *Bixa orellana* are plants that have anti-malarial properties [93], and *Alchornea laxiflora* (Breth.) is traditionally used for malaria treatment in Nigeria and belongs to the family Euphorbiaceae. The oral application of *Enantia chlorantha* has been used traditionally to treat ailments, most especially malaria, and can cause toxic effects

Table 5 Herbal plants, extracts, and results in treating malaria parasites

S/N	Malaria parasite	Herbal plant	Mode of Extraction	Results	References
1	*Plasmodium falciparum*	Sensitivity to *Diospyros monbuttensis* (Egun eja)		High anti-plasmodial activity ($IC_{50} = 3.2$ nM)	[98]
		Sensitivity to *Momordica charania* (Ejirin)		High anti-plasmodial activity	
		Sensitivity to *Morinda lucida* (Oruwo)	Ethanolic	Low anti-plasmodial activity ($IC_{50} = 25$ nM)	
		A. laxiflora		Significant anti-malarial activity in mice	[100]
		P. berghi	Ethyl acetate	Fights against chloroguine-sensitive (Pf3D7) and resistant (PfINDO) strains in mice	
2	*Eimeria* parasites	*M. lucida*		Drugs for poultry birds and veterinary purposes	[101]
3	*Plasmodium berghei*	*L. owariensis*	Methanol	Significant anti-plasmodial activity in albino mice due to presence of flavonoids, alkaloids, saponins, and tannins in the extracts	[102]

when administered in excessive dosage [99]. Table 5 presents dome herbal plants and their effects on malarial parasites.

Azadirachta indica is a common plant in Africa, and its extracts have exhibited potential for pharmacological anti-plasmodial activities [103]. The plant belongs to the Meliaceae family, its use as anti-malarial treatment is not yet ascertained, and this area calls for more research [103]. It was reported in an in silico study that nimbinone, numbone, and margolonone were identified as compounds that are functional and have the ability to modulate *P. falciparum* heat shock protein 90 (PfHsp90) activities.

3.3 Anti-fungi Activities of Medicinal Plants

They are infections caused by fungi and have the tendency of causing serious problems and life-threatening diseases [104, 105]. Fungal diseases that are severe may occur from other health issues such as asthma, cancer, organ transplant, and human immunodeficiency virus (HIV) [106]. These diseases vary based on the region as presented in Table 6. Different herbal plants have diverse anti-fungal activities some of which are presented in Table 7.

Table 6 Fungal infections in some countries and prevalence

S/N	Countries	Fungal infections	Prevalence	References
1	Nigeria	Cryptococcal antigenemia and subclinical histoplasmosis	HIV/AIDS patients, babies in neonatal intensive care	[107, 108]
2	Cameroun	Cryptococcal meningitis, oesophageal candidiasis, *Pneumocystis* pneumonia, disseminated histoplasmosis, and invasive aspergillosis	Adults	[109]
		Tinea capitis	School children	[109]
3	Mozambique	*Emergomyces* and recurrent *Candida* vulvo-vaginitis	HIV and hospitalized patients	[110]

Table 7 Some herbal plants, mode of action, and antifungal activities

S/N	Herbal plant	Mode of action	Mode of extraction	Treatment	References
1	*Calotropis procera*	Inhibition of *Microsporum* and *Trichophyton* species after inoculation for 10 days	Water	Eczema, leprosy, syphilis, malaria, and cutaneous infections	[111]
2	*Spondias mombin* (bark and leaves)	Contains alkaloids, terpenoids, glycosides, flavonoids, and saponins	Crude methanol	Anti-candidal effects	[112]
3	*Psidium guajava*			Active on *Candida albicans* from patients that are infected	[113]
4	*Alchornea laxiflora* leaf extract	Contains flavonoids, alkaloids, tannins, saponins, and reducing sugars		Antibacterial and anti-fungal activities	[59]

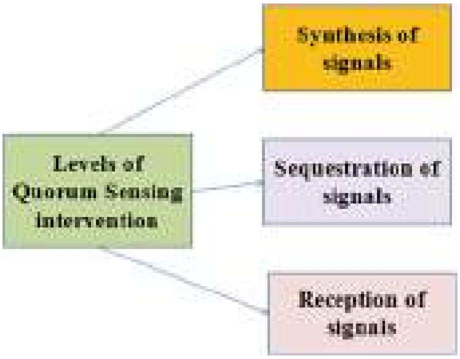
3.4 Antiviral Activities of Medicinal Plants

A fundamental approach towards producing an antiretroviral drug is reverse transcriptase encoding which acts in viral genome reverse transcription in human immunodeficiency virus type 1 (HIV-1) [22, 114]. Some plants were screened and showed antiretroviral activities (Table 8); examples of such plants are *Ancistrocladus korupensis* [103] and *Ancistrocladus congolensis* [115] produced michellamine A and B [21], and *A. congolensis* [115].

Table 8 Some medicinal plants with antiviral properties and their activity

S/N	Country	Virus	Form of extracts	Herbal plant	Part of plant extract	Activity	References
1	Nigeria	Echovirus prototypes 7 (E7), 13 (E13), and 19 (E19)	Methanolic	*Macaranga barteri*	Leaves	Highest anti-viral activity on E7 and E9	[116]
				Ageratum conyzoides	Leaves	Activity highest on E7 and E19	
				Mondia whitei	Leaves	Leaves extract on E7 and E19	
2	China	HIV-1 virus		*Rheum palmatum* and *R. officinale extracts*		Inhibition of HIV-1 reverse transcriptase-associated DNA polymerase (RDDP) and ribonuclease H activities	[116]

Fig. 2 The levels of quorum sensing interventions. (Source: Ref. [120])



3.5 Mechanism of Action of Medicinal Plants

Due to the rare occurrence of disease outbreaks in plants in the wild, it can be said that they have competent defence mechanisms to fight and protect against infectious diseases. Different action mechanisms can stimulate the action of antimicrobial activities such as:

- Enzymes and toxin activity inhibition
- Bacterial membrane damage
- Virulence factors suppression
- Biofilm formation
- Protein synthesis inhibition
- Quorum quenching [117]

Tannins can bind proteins, and this is their major mode of action thereby causing the synthesis of proteins in the cell [23, 118, 119]. The quorum sensing intervention during the mode of action synthesis is in three levels as presented in Fig. 2.

4 Methods of Herbal Medicine Preparations in Nigeria

Herbal medicine can be prepared using various methods, and principally, the medicinal plants are exposed to various treatments so as to extract the active ingredients and phytochemicals present. Some of the methods are:

- Extraction
- Distillation
- Expression
- Fractionation
- Purification

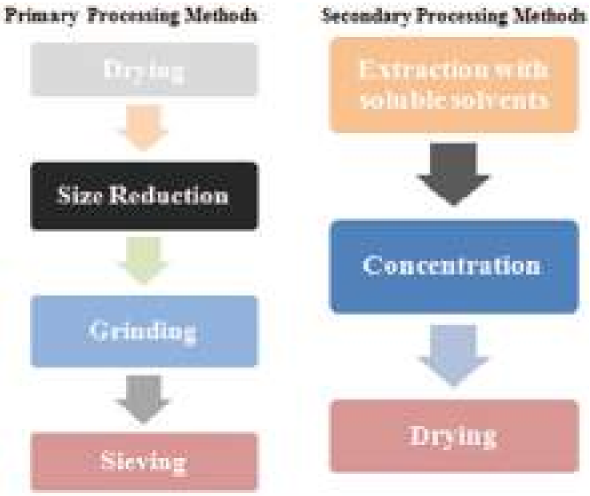


Fig. 3 Primary and secondary medicinal plant-processing methods

- Concentration
- Fermentation

The method of processing is very vital and is connected with the potency of the active ingredients in medicinal plants. The parts to be processed may be the rhizomes, roots, seeds, bark, fruits, leaves, stems, and flowers. It is therefore essential to determine the suitable technique of processing so as to maintain the optimum quality of the herbal product because the value of the herbal product is related to the active ingredients in the plants. The major processing steps are expressed in the flow chart in Fig. 3. There are two types of processing methods: primary and secondary processing methods. The products derived from secondary processing methods can be in the form of extracts which can be whole, concentrated, or powdered form. The form of the extract is then standardized based on herbal regulations [121]. The most common method of extraction is by boiling the plant to dissolve the chemicals. The roots, stems, bark, and rhizomes may be dissolved, and the process is called decoction. In this process, the plant is first dried then cut, so it can dissolute maximally, and finally boiled in water to extract oils, organic compounds, and other dissolved compounds [122]. Instead of water, glycerol or aqueous ethanol may be used for extraction.

4.1 Practices of Herbal Medicine

The origin of herbal medicine is ancient as it involves the use of medicinal plants to heal all forms of diseases and ensures the well-being of humanity. In practice, the healer can make use of substances such as money, seeds, bones, cowry shells, animal shells, use of herbs, and some other spiritual methods to cure ailments. The practice and its use have been studied extensively in Nigeria curing chronic illnesses among the adult and paediatric populations. It has been used to treat epilepsy [123], diabetes [124], hypertension [125], cancer [126], asthma, and sickle cell [127]. The studies on the use of herbal products among the general population are few [128, 129]. Oreagba et al. [130] assessed the herbal medicine use and prevalence among adults without illness in Lagos, Nigeria. Currently, the use of herbal medicine has various patterns used by respondents during the study, and its practices have been reported among adults with hypertension. The rate in the study was three times the value (23%) that was reported in children with epilepsy, sickle cell, and asthma. Some of the natural herbal medicine preparations used are agbo jedi-jedi, agbo iba, herbal toothpaste, jebu-ode mixture drink, splina, and omega roots.

4.2 Relevance of Herbal Medicine Use

Herbal plants naturally occurring are exposed to little industrial processing and are used to treat different ailments. They are known to be completely active ingredients, which may be concentrated in the leaves, roots, and stems, and are used for herbal preparations. The plants can produce materials such as oils, gums, juices, glycosides, and essential oils and may contain recipients. Herbal medicine played an important role in the treatment of Severe Acute Respiratory Syndrome (SARS) in China [130]. It helped to contain and treat severe issues of SARS. In Nigeria, the use of traditional herbal medicine is beginning to gain popularity. Its historical health benefits have shown that herbal medicine is an important and significant part of alternative medicine. It is a part and parcel of alternative treatment methods. Herbal medicine involves the use of different parts of the plant. At the moment, a high percentage of Nigerians, most especially in rural and remote areas, use herbal medicines as a principal source of healthcare [54]. It can also provide economic returns for people who depend on the use as a means of income. There are some factors affecting the acceptance of traditional medicine in Nigeria. They are:

- Some herbal remedies are affordable and very efficient.
- The use of herbs as food and medicine has been time immemorial therefore creating an avenue for acceptance.
- Communities may have a historic/cultural tie with some herbal medicines they use.
- Herbal medicine is perceived to have a strong emphasis on health than disease treatment.

5 Proposed Nigerian Medicinal Plants for Standardization

With the immeasurable benefits from various Nigerian medicinal plants and efforts to improve and harmonize the practice of traditional medicine in Africa, it has been proposed by the African Regional Standard Organization (ARSO) which is formed by the African Union (AU) to adopt ten plants that have medicinal properties in

Table 9 The proposed ten Nigerian plants for certification by Nigerian Medical Council (NMC)

S/N	Common name	Botanical name
1	Moringa	*Moringa oleifera*
2	Bitter kola	*Garcinia kola*
3	Scent leaf	*Vernonia amygdalina*
4	African bush mango	*Irvingia gabonensis*
5	Yellow yam	*Dioscorea bulbifera*
6	Red stinkwood tree	*Prunus africana*
7	Baobab	*Adansonia digitata*
8	Zobo	*Hibiscus*
9	Cashew	*Anarcadium occidentale*
10	Bitter leaf	*Vernonia amygdalina*

Source: Ref. [131]

Nigeria. The body is a nongovernmental organization that is aimed at standardization and regulation of clinical practices in Africa. The ten plants are categorized as Functional Food Plants of Africa and are listed in Table 9. The listed plants are captured in Nigeria as Food and Medicine.

The proposed plants were selected because they have been well-researched and have economic, financial, social, and health impacts. For instance, the African bush mango is a drug in Europe used for weight loss. It is locally called Ogbono and is of various types. Because of the lack of standards, people sell products that are not genuine as cases have been reported about people from Asia who sold drugs that they claim have contents that are not found in their drugs. *Prunus africana* is a plant on the red list of the International Union of Conservation of Nature (IUCN) as it cannot be traded or moved between country boundaries. The plant functions basically for inhibiting prostate enlargement and is commonly used in South Eastern Nigeria.

- ***Moringa oleifera***

It is commonly called the drumstick tree and is referred to with various names based on ethnicity in Nigeria. It has been reported that the plant strengthens the immune system of the body, is a natural energy booster, can cure migraines, asthma, and headaches, has an antibiotic potential, can reduce arthritis and pains, and inflammations, and can restrict the growth of tumours. The flower of the plant when boiled with soymilk is a good aphrodisiac. The fruit can boost sperm count and improves egg fertilization chances in men. It is enriched with iron and has more Vitamin C content than oranges. It has four times more calcium than milk and more Vitamin A than carrots. It contains double the protein as milk and triple the potassium as a banana. It can function in body detoxification and expelling harmful substances as wastes. It has the potential to address issues of malnutrition and can be taken by people with Human Immune-deficiency Virus (HIV)/Acquired Immune Deficiency Syndrome (AIDS). Nursing mothers who consume the plant have been reported to produce more healthy milk, and children gain more weight after leaves are added to their diets as supplements.

- ***Garcinia kola***

It is commonly called bitter cola, and it belongs to the Guttifereae family. It is called differently based on ethnicity in Nigeria. It has been reported by scientists in Nigeria that eye drops made from this plant have the ability to prevent blindness in patients suffering from glaucoma.

- ***Vernonia amygdalina***

It is called the bitter leaf and belongs to the family Compositae. It is called differently by various ethnic groups in Nigeria. It is a good panacea for cancer, diabetes, damage of the liver, infections that resist drugs, and safety in childbearing. The plant has been reported to pass human trials as an anti-diabetic medication and has received a United States Patent 6,531,461. The aqueous extract of the plant collected from Benin City has also been received by United States Patient 6,849,604 as a treatment for cancer. Researchers in Nigeria have reported the plant as a good protection against liver damage by acting as an antioxidant. The roots and leaves have been reported to increase the contraction of the uterus and motility thereby promoting safer childbirth. It is also useful in the management of the placenta that is retained, malaria, infertility, colic pains, and painful menstruation.

- ***Anacardium occidentale***

It is commonly called cashew and belongs to the family Anacardiaceae. It is called jambe in Hausa, and Kaju or Kantonoyo in Yoruba. The extract of seeds is an effective anti-diabetic agent. The tree and its products have been known to be an effective anti-inflammatory agent and reduce blood sugar and diabetes. Eating fruit, nut, and leaf extracts is good for tackling high blood pressure. The nuts can improve the sensitivity of a reflex called the baroreflex which is important in maintaining the level of blood pressure. A gram-positive bacterium that is responsible for the decay of teeth, tuberculosis, acne, and leprosy can be killed when cashew nuts, apples, and shell oil are consumed.

- ***Ocimum gratissimum***

It is commonly called scent leaf and is a member of the family Lameacea which is a mint family. It is referred to by the Yorubas as effirin and Ibos as arigbe or nchuanwu. It is a herb that can reduce physical and emotional stress, and improve anxiety and depression. Locally, the plant is used for treating diarrhoea, headache, and infection of the kidney and wart worms. Leaves contain thymol oil which is an antiseptic and can prevent bites by mosquitoes.

- ***Irvingia gabonensis***

It is a common fruit consumed in Nigeria and West Africa and is commonly called Wild mango or West African mango. It also has other names such as native mango, dika nut tree, bush mango, and dika bread tree. The name of the fruit varies with the ethnic group in Nigeria. Ogbono helps to reduce fat in the abdomen, reduce weight, and lower cholesterol and the chances of diabetes, cancer, stroke, heart disease, and kidney failure.

- ***Dioscorea bulbifera***

It is commonly called several names such as yellow yam, air yam, air potato, potato yam, cheeky yam, and bitter yam. It belongs to the family Diosoreaceae. It is known to cure dysentery, diarrhoea, and other ailments.

- ***Prunus africana***

It is called the red stinkwood tree and belongs to the family Rosaceae. The wood has an unpleasant odour which is the reason for the name stinkwood. The bark is used to treat health conditions by traditional healers such as enlargement of the prostate, erectile dysfunction, diseases of the kidney, infections of the urinary tract, stomach upset, chest pain, stomach ache, wound, baldness in males, and inflammation. The bark is also an aphrodisiac that enhances sexuality and vitality, especially in men. The plant has been reported to have bioactive substances with anti-cancer, anti-inflammatory, anti-microbial, and antiviral effects. Some of the compounds are sterols, coumarin, triterpenes, and flavonoids which have medicinal properties. The harvesting of the plant has been on the increase due to its properties and has the potential of saving the world from deadly prostate cancer.

- ***Adasonia digitata***

It is commonly called baobab by the English, Portuguese, and French. It is called several names based on ethnicity in Nigeria. The seeds, leaves, fruits, flowers, fruit pulp, roots, and bark baobab are edible and have been extensively researched. The fruit pulp is rich in calcium, vitamin C, phosphorus, carbohydrates, potassium, fibres, proteins, and lipids. It can be used in seasoning as an appetizer and in the production of juices. Seeds contain high levels of zinc, magnesium, phosphorus, iron, sodium, manganese, lysine, calcium, iron, and thiamine. It has biological properties such as antimicrobial, and anti-malaria, and can cure diabetes, anaemia, diarrhoea, and anti-inflammatory activities. The active ingredients are flavonoids, phytosterols as well as vitamins and minerals.

- ***Hibiscus sabdariffa***

It is commonly called zobo or roselle and is a member of the family Malvaceae. It is known to lower blood pressure and cholesterol and inhibits the invasion of human prostate cancer cells. The polyphenols that are contained in the leaves of hibiscus have the ability to inhibit the growth and destroy the growth of melanoma cancer [131].

5.1 Threats of Nigerian Herbal Medicine Sources

Some of the herbal associations are the Nigerian Traditional Medical Association (NTMA) and the Nigerian Union of Medical Herbal Practitioners (NUMHP), and their roles are:

- Ensuring quality control.
- Regulating pricing.
- Regulating the mode of herbal product marketing.
- The screening of members for authenticity: Fake members are sent out of the organization.
- Lobbying for recognition from the government, and this has been achieved by the organization.
- Interaction with an alternative practice of healing which are the orthodox practitioners of medicine, and this has so far not been achieved by the organization.
- Establishing gardens with herbal plants across the country.

The Nigerian Natural Medicine Development Agency (NNMDA) is also concerned with the regulation of herbal practices and has initiated activities and programs that are aimed at documenting medicinal plants and animals used in herbal medicine. They develop strategies that can be used to boost the nation's Indigenous non-medication, and techniques used in the practice of herbal medicine. The management of herbal plants is crucial because of the value they have and are potential drug sources for improved health care and economic promotion and biodiversity conservation. Many plant species have become scarce to collect in the wild due to the prevailing threats; likewise, the species available are prone to disappear due to the present condition in the wild. If they disappear, where can the species be sought? It was said by Soladoye and Olowokudejo [132] that if this continues, many industries and factories will become extinct. About 480 plant species in Nigeria are endangered as a result of increasing pressure from the population, forest logging, and clearing of lands for development and urbanization [133, 134]. It was reported by the International Union of Conservation and Nature (IUCN) [135] that about 560 Indigenous tree species are found in Nigeria, 16 critically endangered, 18 endangered, 138 vulnerable, 2 species are conservation dependent, 15 near threatened, 10 data deficient, and 173 least concerned. This translates that the endangered flora in the Nigerian ecosystem is fast increasing and the role of government has not been promising in the use of herbal plants. A vital approach may be to adopt approaches for the conservation of herbal plants thereby preventing the loss of total forest [136].

6 Future of Nigerian Herbal Medicine Practices

Considering the numerous herbal plants found in Nigeria, the future of herbal medicine seems very promising. There is quite a number of plants with medicinal potentials that are yet to be investigated for their compositions so as to be used as appropriate. The study of herbal plants and their therapeutic potentials have created a space for understanding the build-up of drugs, design, and development of the sector. The future of herbal plants can positively affect the practice of medicine as new diseases and pathogens are discovered daily and this calls for the use of complementary medicines to address them [10]. There is also an urgent need for new strains of drugs as microorganisms have begun to resist antibiotics; there is an immediate and urgent demand for discovering safe and natural compounds that can be used for this purpose. There is also an increase in the use of herbal plants as nutraceuticals and functional foods, thereby used as preventive medicine and searching for a solution to the issue of drug resistance by microorganisms [3].

7 Conclusion

From this review, it is evident that Nigeria has diverse medicinal plants which are identified by different names based on ethnicity. These plants have been seen to have potential as an alternative therapy to avert the spread of pathogens that are multidrug-resistant and the toxicity of some antibiotics. It has also been observed that these medicinal plants are on the verge of total disappearance as a result of the destructive practices by humans who do not value their use; therefore, sustainability and conservation are far from these medicinal plants. Nigeria lacks adequate information on some medicinal plants and most importantly their characterization and chemical composition towards their use. The investigation of bioactive components in Nigerian medicinal plants is few; therefore, the ethno-medicinal and phytochemical screening of these plants are yet to be validated. The knowledge which is Indigenous about medicinal plants is also diminishing as younger generations need to be enlightened on the importance of medicinal plants and the role they can play in human health. Due to the enormous therapeutic uses of medicinal plants, adequate research into novel plants and compounds can cure neglected tropical diseases (NTDs) that are endemic in Nigeria. There is also a dire need to strategize approaches that are reliable for the conservation of medicinal plant diversity and documentation of knowledge that are Indigenous for generations as native plant species are an important constituent of Nigerian and African traditional medicine.

Abstract

Herbal medicine utilization has the potential to stimulate sustainable development and influence livelihood of societies in diverse ways. This review will update and inform healthcare authorities and decision-makers about the value of herbal medicine in actualizing the sustainable development goals of adequate healthcare system for all by 2030. This chapter is poised to provide an overview about the role of herbal medicine in stimulating sustainable development in remote societies. Thus, the chapter reviewed and extracted important information's from a plethora of sources on sustainable development subject matter. The review highlights common types of herbal medicines used to treat illnesses, adverse effects, challenges, and the way forward in making herbal products acceptable globally. However, the growing demand for herbal medicine today is greatly contributing to the growth of developing countries' economy while at the same time improving livelihoods. The study finds that the increase in demand and value of herbal medicines today is closely connected with the rise in knowledge of the therapeutics, phytochemical properties, availability, affordability, and inexpensiveness of the herbal products as compared to modern drugs. The chapter further concludes that herbal medicine sustainability is impeded by various factors ranging from uncontrolled deforestation, climate change, absence of policies on herbal medicine usage, anthropogenic activities, and limited collaboration between modern and herbal medicine practitioners. It is concluded that herbal medicine plays a key and central role in the sustainable development of local communities through the strengthening of healthcare system. It is recommended that more collaboration be sought between modern healthcare specialist and local herb practitioners in developing countries.

1 Introduction

Herbal medicine is described as the combination of knowledge, skills, cultural experience, beliefs, and theories applied in the maintenance of human health through herbal materials prepared from active plant ingredients to diagnosis, prevent, and treat complex and complicated mental and physical illness incur by humans [1–3]. The increase in the demand of herbal medicine over the past decades is closely connected with its affordability, efficacy, cultural acceptability, inexpensiveness, and the treatment of diseases deemed incurable by modern health drugs and practitioners. These medicinal properties and qualities from herbal medicines have attracted the attention of modern health practitioners to incorporate herbal products in clinical research to unearth more healing properties in herbal products [1]. According to the WHO [4] estimate, about 50–70,000 plant species have medicinal attributes and component contained in them [5]. The plant components from which herbal medicines are derived are flowers, seeds, roots, stems, bark, fruits, and leaves [6]. These herbal components comprise of nutritional supplements that are extracted and prepared for intake [7]. In addition, herbal medicines are formulated into major forms: powdered and liquid [8–10]. Herbal medicines have in time immemorial ensured that local people live healthy lives and stay well all through their lives.

The role of herbal medicine in the maintenance of healthcare system is critical and differs by countries, regions, and countries. Scientific literature suggests that more than 80% of the world population still relies on herbal medicines for their healthcare needs [11–13]. For instance, Asia and Africa utilized more herbal medicine than other continents. That is to say, 80% of South Africa's population use herbal medicine to meet their healthcare needs as compared to 40% of Sierra Leonean relying on herbal medicines for medication [14, 15].

Globally, the value and the sustainable use of herbal medicine have been studied extensively over the past decades [16–18]. According to WHO [19], herbal medicines are described as the use of herbs consisting of therapeutic properties emanating from plants parts such as bark, leaves, seed, flowers, and roots. The increase in value and demand for herbal medicine is growing and contributing to the sustainable development of mankind overtime [20]. Nonetheless, the manner in which herbal medicine contributes to the sustainable development of society is poorly understood, and research especially in a developing country like Sierra Leone is unrealistic. The health of humans especially those living in rural communities greatly depend on ecosystem for the provision of goods and services that support healthy living in the form of medicine, food, shelter, clean water, and recreation among others [21]. Herbal medicines have been in existence for many decades with little or no major complication and implication [22]. In the era of pandemic outbreak, herbal medicines are witnessing a growing demand and awareness in terms of the benefits and importance of herbal medicines in tackling complex pandemic ailment especially in developing countries. These herbal medicines are critical in supporting the sustainable development goals in diverse ways. The sustainable development goals are the UN set of 17 goals with 169 targets to better the lives of mankind by 2030 [23]. In particular, SDG 3 focuses mainly on the sustainable health of human being.

1.1 Sustainable Development in the Context of Herbal Products in Developing Countries

Globally, herbal natural products have in time immemorial been used in many countries and industries to cure various ailments and have attracted global attention over the past centuries [24]. The sustainable development of herbal products is impinged by the high levels of dosage and misconception problems characterized by lack of clinical approval of herbal medicine drugs. However, the growing demand for herbal products today is greatly contributing to the growth of developing countries' economy and enhancing rural livelihoods. In such, the sustainable harvesting of herbal products has the potential to benefit herbal practitioners, improve their livelihood activity, contribute to environmental sustainability, social equity, and economic wealth, and improve healthcare system in remote communities.

Herbal medicine usage and utilization are rooted in indigenous knowledge and embedded in most local community lifestyle for years [25, 26]. These products have been used to provide natural solutions to healthcare issues in societies in a sustainable manner [24]. Natural herbal products are mostly categorized into food and medicinal products and are mostly derived from plant species. These herbal products have contributed to the sustainable development of society through livelihood security, affordable healthcare system, provision of income, creation of job for traditional healers, and provision of food supplement for local indigenes [25, 27]. While 80% of the developing world relies on herbal medicines for the healthcare needs, the developed world indirectly depends on herbal medicine for healthcare with 25% of modern pharmacy products derived from herbal plants [25, 28]. These herbal medicines are vital in the sustainable development goal agenda for the current and future generations. Herbal medicines play a critical role in achieving the sustainable development goal target of healthy lives in a healthy environment.

1.2 Herbal Medicine Sustainable Development Potential

As the sustainable development goal is geared toward living a healthy live for all, herbal medicines play an integral part in achieving this goal. Recent studies suggest that a wide range of therapies from herbs plays a critical role in the well-being of people regardless of race, color, and social status [29]. Specifically, herbal medicines stand the chance to meet target 3.8 of the Sustainable Development Goals (SDGs) that aim to ensure that there is a universal access to healthcare system for all that is free from financial risk, considered safe, and affordable for all class of people and is effective in fighting future pandemic [30].

Herbal medicine is a catalyst of sustainable development due to the fact that it enables new drugs to be discovered, readily available for all class of people, and cheap and support socioeconomic activities and livelihood. Herbal medicine further contributes to sustainable development through the provision of self-employment, household income, livelihood enhancement, support to healthcare system, and socioeconomic activities among others [29]. Today, majority of the global population consider plants as the primary source of healthcare that plays a critical role in the sustainable development of societies [31]. Plant species used to prepare herbal medicine has the potential to enhance the production of life-saving drugs that will contribute to sustainable development of the current and future generation [32]. Hence herbal medicine is an important tool for the sustainable development of healthcare system especially in developing countries [33]. In low-income countries, the sustainable economic development of local economies is greatly dependent on natural products like herbal medicines derived from plants. The sustainable use of herbal medicine provides a reliable source of livelihood and household income for remote communities of low- and middle-income countries like Sierra Leone. In such, the transfer of herbal medicine knowledge from generation to generation is a sustainable means of preserving drugs that will benefit society positively.

In Sierra Leone, herbal medicine plays a primary role in the day to day healthcare activities of people and is being considered an alternative source of employment, income generator, and environmental sustainability alternative. In Sierra Leone and other parts of the world, trade in herbal medicine has been a sustainable source of livelihood for traditional herb practitioners, middle men, and hawkers across the street and towns. Herbal medicines ensure the access to local medication easy for hard to reach communities within Sierra Leone while at the same time strengthening the fragile healthcare system that in turn enhances sustainable development [33]. Herbal medicines don't only enhance the realization of the sustainable development goals but serve as a source of income for local practitioners. Trade and practice in herbal medicine serve as a source of sustainable income and self-employment for local practitioners in developing countries.

1.3 Herbal Medicinal as a Sustainable Source of Income

Herbal medicine has been and is still a sustainable source of income in developing countries around the world. Herbal medicine practice and trade are important industry and business ventures that serve as the source of income for many herbal medicine practitioners around the world [34]. For instance, Sierra Leone has more than 45,000 herbal medicine practitioners nationwide [18]. Across Sierra Leone and in other part of Africa, many local indigenes relied on the additional income provided through herbal medicine sale and practice to supplement their basic needs on a daily basis. According to Zion Market Research, the global income generated by the sale of herbal medicine was reported to be estimated at USD 166 billion in 2021 and is expected to reach USD 348 billion by 2028 at an annual rate of 11.2% [22]. For instance, the value of herbal medicine trade in Sierra Leone over the past decades is estimated to be USD 64,000 annually [15]. The world herbal medicine market value and size in 2021 was valued at USD 151.91 billion and in 2022 was valued at USD 165.66 billion and is projected to worth 347.50 billion by 2029 respectively [35]. Similarly, the UN Comtrade [36] statistics reported that aromatic and medicinal plants are valued around USD 800 million per year at a growth rate of 15–25% [37].

Nonetheless, the trade value or income generated by this trade over the past decades in Sierra Leone is undocumented and under reported. In most part of Africa, the trade and income received from the sale of herbal medicines serves as an important source of livelihood and a major contributor to household income and the gross national products [34].

Across Africa, herbal medicine used for healing various illnesses is used as a profession to earn income [38]. Herbal medicine practitioners in middle- and low-income countries use this profession as trade upon which their sustenance and survival depend. Hence, they directly or indirectly demand a reward for their service in cash or in kind. Any given amount is mostly accepted, but the more you give, the more attention would be given to your situation. Compared to modern healthcare treatment cost, herbal medicines are perceived to be less expensive, more affordable, easily accessible, and readily acceptable in society today [39]. In most low- and middle-income countries where poverty and unemployment are rampant, herbal medicine practitioners' cost of medication is considered by many as cheap, affordable, and an important source of healthcare drugs for the low-income earners [40]. Across Africa and in other parts of the world, the herbal medicine trade is mostly done by the informal sector and is now traded in local markets by individual hawkers on the streets of urban and peri-urban communities. A study conducted by

Mander et al. [34] in South Africa indicated that about 74% of herbal practitioners, street traders, and herb harvesters are women mostly from rural settings. Herbal medicine products are sometimes sold as raw materials or process mixture of different plants by traditional health practitioners or traders for profit making. Recent estimate in herbal medicine trade by WHO is estimated around US$100 billion and still has a great potential of expansion in the next coming years. The WHO estimated that herbal medicine annual growth rate is around 15% and is derived from trade in herbal raw materials, medicinal plants, and other herbal products. The higher demand of herbal medicine is stimulated by shortage and high cost of western drugs as well as the introduction of counterfeit or fake drugs by criminal drug cartels.

2 Global Concept of Herbal Medicine Utilization

Herbal medicines include the combination of traditional knowledge on plant therapeutic experience spanning from many generations [41]. Herbal medicines are considered to offer a great deal of alternative treatment for sicknesses ranging from disease and other life-threatening ailments that positively affect the health of societies. Herbal medicines have over the past centuries evolved and became a strategic mainstream healthcare therapy with great drug development prospect for the human race [40]. There are different points of views on herbal medicines depending on localities and civilization. According to WHO [42], herbal medicine is characterized and includes any herbal material prepared by health practitioners from natural products containing active ingredient capable of treating complex ailment to those treating common cold and fever. Herbal medicine is perceived by traditional healers to have phytoconstituents that are well-matched with the human health system [43]. Herbal medicines comprise of many plant-extracted substances in the form of homemade infusion, dried products, seed, leaves, bark, etc. [44].

Herbal medicines have been in use for centuries as is considered a life-saving dietary that prevents and cures diseases and are considered by many as alternative medicines to western drugs. Even today, 60% of the global population and 80% of the population of developing countries rely on herbal medicines to supplement primary healthcare especially remote societies [45]. Herbal medicines have been reported to cure sicknesses like AIDS, skin disease, cancer, hypertension, diabetes, mental disorder, and tuberculosis among others [41]. On the global stage, herbal medicine is still supporting the health system of some countries like Egypt, China, Bhutan, India, South America, Mali, Sierra Leone, South Africa, and many more in tackling complex and complicated ailments that modern drugs can't treat efficiently [41]. The rise in demand for herbal medicines is closely associated with the herb's abundance, presumptive efficiency, easy access, inexpensiveness, quick reaction, and safety [41]. Nonetheless, critics have raised series of concerns about the prescription, consumption, standardization, and side effects posed by herbal medicines over the years [46]. For instance, the State Health Director of California in the USA once issued a warning in 2001 about the prescription and consumption of herbal product made from Anso Comfort capsules on the pretext of undeclared

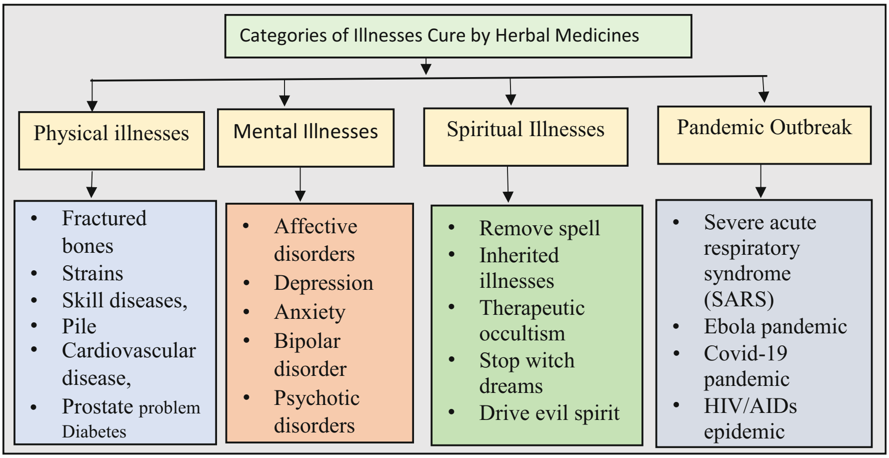

Fig. 1 Category of illnesses cured by herbal medicine

benzodiazepine chlordiazepoxide in the herb [46]. In most places around the world especially in developing countries, herbal medicines have been proven to cure physical, mental, spiritual, and pandemic illnesses (Fig. 1). The value of herbal medicine is hard to quantify due to the fact the practice does not require legal license in most cases.

2.1 The Value of Herbal Medicine to Society Today

The forest ecosystem is widely recognized as a reservoir with great importance in terms of job creation abilities, provision of food supplement, and other ecosystem services of great livelihood benefits and significance [47]. The value of herbal medicine can be expressed in healthcare service provided and income generated through trading. The increase in demand and value of herbal medicines today is closely connected with the rise in knowledge of the therapeutics, phytochemical properties, and the availability, affordability, and inexpensiveness of the herbal products as compared to their conventional medicine counterpart. This knowledge has aided the switch from 100% use of modern medicine to 50% use of herbal products [47]. This switch has boosted the market value especially during the COVID-19 pandemic when herbal medicines were used as a supplement to western vaccines. Nonetheless, there are a number of factors driving or propelling the use and value of herbal medicine especially during the pandemic and post-pandemic period. These factors are not limited to rising herbal therapy knowledge, affordability, growing public awareness, homeopathy, and dietary supplement treatment cost but by failure of modern medicine in treating complicated illness [7].

Herbal medicine has been in used for centuries and demonstrate great therapeutic phytochemical benefits, safety, and efficacy that has and will stand the test of time.

Herbal medicine value and contribution have not only been realized in the effective treatment of complicated illnesses but strive to meet the health needs of society for many centuries. For many in deprived communities around the world, herbal medicine is the only source of healthcare that is readily available, affordable, and accessible for all class of people. The phytochemical and therapeutic components of herbal medicines have contributed to the development of modern drugs sold in pharmacies around world today. Historically, more than 30% of modern drugs are directly or indirectly derived from plants. Recent data shows that lower income nations are the key actors and consumers of herbal medicine due to few healthcare infrastructure and weak purchasing power in those countries [19]. Hence, these societies value herbal medicine than other communities today. Besides the various illnesses cured by herbal medicines, the products have shown great potential in tackling emerging pandemic outbreak. For instance, countries like China and Madagascar employed herbal medicine in the fight against COVID-19 and other recent outbreaks. In such, if attention is given to herbal medicines and advance research is conducted, these products have the potential to tackle emerging pandemic outbreak with ease in the near future.

2.2 The Role of Herbal Medicines in Tackling Emerging Health Pandemic

The COVID-19 caused by SARS-CoV-2 and the Ebola formerly known as Ebola hemorrhagic fever are the two most recent pandemics that have devastated and killed millions around the world [48]. Scientific evidence has proved that herbal medicine helps to ease SARS-COVID-19 infectious disease [49]. During these pandemic periods, low- and middle-income countries like Sierra Leone, Guinea, Liberia, Togo, and Ghana relied on vaccine sharing arrangement from wealthy nations to vaccinate its population. Nonetheless, only around 10% of middle- and low-income countries received at least a single dose of vaccine [50]. Although COVID-19 and Ebola has negative impact on lives and the world order, it also has positive impact on the use and reliability of herbal medicine to tackle future pandemic outbreak. In most low- and middle-income countries, people have turned to herbal medicines to cure illness caused by the pandemic using well-prepared herbal infusions [51]. In some parts of the world, herbal medicines increase exponentially during the COVID-19 periods. For instance, in Malaysia, some ethnic groups use herbal medicines to tackle the Covid-19 pandemic during the peak period when vaccine access was difficult [51]. Similarly, in Madagascar, the Malagasy Institute of Applied Research developed a cure for coronavirus called "Covid Organics (CVO)," an organic herbal concoction. This organic herbal concoction cure was believed to cure COVID-19 patients suffering from the infection [52]. This organic herbal concoction was requested by Tanzania, Equatorial Guinea, the Republic of Congo, Guinea Bissau, and Sierra Leone among other countries in Africa [52]. According to a recent study conducted by Ekor [53], herbal medicines contained phytochemical components that have the potential of curing or deterring coronavirus infection accordingly. However, more studies are ongoing to prove the efficient of herbal medicines as an alternative complementary approach in tackling COVID-19 and other future pandemic outbreaks using herbal drugs to provide needed immunity [54]. In Asia and Africa, local populations are refocusing on herbal medicines as remedies to cure many emerging diseases at a low cost [55]. In Africa, countries like Madagascar have shown the importance of herbal medicine in fighting complicated and complex health crisis capable of wiping out generations. The emergence of global pandemic like COVID-19 and Ebola has brought recognition to herbal medicines potential in curing complex ailment that western drugs struggle to cure at a cheap cost. A recent study by Demeke, Woldeyohaninsg, and Kifle [49] revealed that herbal medicines have the capability of interfering with COVID-19 pathogenesis by hindering the SAR-COVID-19 replication process and infection. The study identifies *Mentha piperita*, *Allium sativum*, *Nigella sativa*, *Citrus* spp., *Allium cepa*, *Artemisia annua*, and *C. sinensis* plant species to contain phytochemical components that inhibit SARS-COVID-19 and is consumed through herbal drink [49, 56]. Similarly, studies conducted by Vellingiri and Rajagopalan [57], Luo [58], and Chan et al. [59] discovered that herbal medicines can reduce COVID-19 severity and in some cases prevent the virus from replication. For instance, India and China use herbal medicines alongside modern drugs to boost the immunity of patients infected by COVID-19 [60, 61]. Moreover, in China, herbal medicines demonstrate the ability to reduce mortality rate, inhibit replication, and improve symptoms signs [58]. Some plant species used as herbal medicine are presented in Table 1. The use of herbal medicines in tackling emerging global pandemic cannot be overemphasized. Herbal medicines have the potential to support various forms of livelihood activities especially in remote and hard to reach communities of low-income countries.

2.3 Herbal Medicine and Its Impact on Livelihood Activities

Globally, the significance of herbal medicine to mankind is basically infinite due to the roles played in enhancing livelihood through the sale of medicinal herbs and the principal source of income for herbal practitioners and their families. Over the past decades, herbal medicines have served mankind in treating complex ailment considered nontreatable and at the same time served as source of livelihood for practicing practitioners. Natural products like herbal medicine also have the potential to enhance livelihood via consumption, treating ailment, and sale of products to provide an economic safety net for herbal medicine practitioners [62, 63]. A study conducted by Timmermann and Smith-Hall [63] concluded that herbal medicine sale gives an opportunity to local herbal medicine practitioners to earn financial incomes capable of supporting their household and enhancing livelihood activities. A similar study conducted in the mountainous region of Nepal found that herbal plant plays an integral role in contributing to livelihood and annual income [64]. Rasul et al. [65] and Shrestha and Bawa [66] supported these claims in their study by concluding that 21% and 85% of household income came from the sale of herbal medicines in Nepal. Across the world, the sustainable use of herbal medicinal plant products is integral in

Table 1 Common herbal plants and their medicinal properties around the world

Scientific name	Family	Medicinal Properties	Reference
Mentha piperita	Lamiaceae	Treat fever, cold, oral mucosa, throat inflammation, and digestive issues and as antiviral and antifungal	[49, 76]
Allium sativum L	Liliaceae	Treat diseases like asthma, bronchitis, influenza, COVID-19, and others	[49, 77]
Allium cepa	Alliaceae	For cough and other infections of the air tubes in children	[49, 78]
Citrus spp.	Rutaceae	Contains hesperidin and rhoifolin properties: treat SARS-COVID-19 pro-inhibition in a dose-dependent manner	[49, 79]
Angelica decursiva	Apiaceae	Contains columbianadin and decreases airway inflammation	[49, 80]
Hibiscus sabdariffa	Malvaceae	Contains anthocyanin-converting enzyme, decreases plasma aldosterone and serum angiotensin	[81]
Salvia officinalis	Lamiaceae	Contains polysaccharide and emollient/ potent antitussive activity	[82]
Aloe barbadensis Mill	Asphodelaceae	Enhances potent antitussive/emollient activity and contains polysaccharide	[82]
Malva sylvestris L	Malvaceae	The Plants Contains Polysaccharide that enhances Gil/Vitaceae as well as Tetrastigma hemsleyanum Diels	[82]
Torreya nucifera	Taxaceae	Amentoflavone, authentic flavones. SARS-3CL pro-inhibition/62% at 100 μg/mL	[49, 83]
Artemisia annua	Asteraceae	Contains many biological metabolic, antitumor, antimicrobial, and immunomodulatory properties	[56, 84]
Ginkgo biloba	Ginkgoaceae	The herb improves circulation and cognition and the leaves aid in asthma and cardiovascular disorders	[85, 86]
Piper methysticum	Piperaceae	Plant used to cure nervous system illnesses, helps in relaxation, induces sleep, and helps in weight reduction	[86]
Echinacea purpurea	Asteraceae	Plant used to cure snakebites, syphilis, toothache, chronic arthritis, among others	[1, 86, 87]
Eleutherococcus senticosus	Araliaceae	Increase body's resistance against stressful situations, treat hypertension, diabetes, depression	[88]
Ephedra sinica	Ephedraceae	Plant used to treat cough, myasthenia, rheumatism, hay fever, enuresis, narcolepsy, among other sickness	[1, 86]

supporting livelihood activities in low- and middle-income countries. For instance, in the northern part of Sierra Leone, the livelihood of most communities depends on incomes derived from herbal medicine practice and healing. The town named "Kabala" is well known for the mystical power possessed by herbal practitioners in that part of the country and is the first choice for people to visit when inflicted with black magic sickness that cannot be cured by modern drugs. Besides, besides livelihood support provided, herbal medicine also supports healthcare system, boosts financial income, and enhances cultural diversity of people [67]. In countries like Guinea, Afghanistan, Ethiopia, Mali, Senegal and Sierra Leone, herbal medicine trade and practice boost household income and support livelihood activities while at the same time save lives. Besides herbal medicine practitioners, middle men dealing in herbal medicine products also rely on these herbs to provide livelihood support for themselves and their household. Herbal medicines do not only support livelihood activities but also contribute to the sustainable development of societies especially in developing countries. A study conducted by Abisoye et al. [68] found that income earned from herbal medicines sale or trade is used to support the livelihood of household by paying for children education, healthcare, feeding, shelter construction, and covering of other expenses. In some remote parts of Sierra Leone, herbal medicine practice and trade are full-time employment with huge financial income potential [62]. Herbal medicine practice has the potential to reduce poverty, enhance social equity, and provide integral resources that enhance sustainable livelihood. Moreover, herbal medicines play a critical role in sustaining local economies and rural livelihood for remote communities and societies. Traditional medicines can also ensure environmental sustainability through increased biodiversity and conservation of herbal plants [69]. Nevertheless, the contribution of herbal medicine to livelihood and household income in most countries around the world is not well captured and documented due to the absence of available database in these countries.

3 Common Herbal Plant Species Use for Medicinal Purposes Worldwide and in Sierra Leone

Plants with medicinal properties are globally a valuable source of healthcare medication from herbal products derived from the natural environment. Scientific literature has confirmed that plants are the primary source of herbal medicine around the globe and they are rich in phytochemical substances used for medication [16, 70]. Plant species differ with geographic location, climate, vegetation, and soil pattern (Table 1). Although some plants are found within a wide geographical area spanning through different continents, some are only found in specific countries or regions (Table 2). The extraction, preparation, processing, and administration of herbal medicine differ by country, culture, experience, and educational level [71]. Similarly, the number of illness or sicknesses that can be cured by herbal plants products also differs by region, country, culture, age, experience, spiritual powers, herb acceptability, and societal norms. Generally, herbal medicines derived from plant products treat various illnesses ranging from severe acute respiratory syndrome (SARS), HIV, prostrate problems, inflammation, cardiovascular disease, and depression, among other ailments [72–75]. Herbal drug products can be prepared, processed, and consumed in different forms and ways such as infusion, syrup, concoction, ointment, teas, rubs, powder,

Table 2 Some herbal plants, diseases cured, and mode of preparation in Sierra Leone

Scientific name	Family	Disease/sickness cured	Part use	Mode
Adenia lobata	Passifloracea	Abscesses, deworming	Leaf, stem	Decoction
Anisophyllea laurina	Anisophylleaceae	Eye problems, stomach pain	Leaf	Infusion, Squeezed juice
Anthostema senegalense	Euphorbiaceae	Abortion	Leaf	Infusion, squeezed juice
Carica papaya	Caricaceae	Constipation, dysentery, fetish, purgative	Leaf	Infusion, squeezed juice
Landolphia dulcis	Apocynaceae	Penis enlargement	Root	Infusion
Cassia alata	Leguminosae	Malaria, constipation	Leaf, bark	Infusion
Citrus aurantifolia	Rutaceae	Constipation, fever	Leaf, root	Infusion
Ficus exasperate	Moraceae	Abortion, malaria	Leaf, bark	Infusion
Funtumia africana	Apocynaceae	Impotency in male	Leaf, bark	Infusion
Gmelina arborea	Lamiaceae	Malaria	Bark, leaf	Infusion
Garcinia kola	Clusiaceae/ Guttiferae	Purgative, throat infection, diarrhea, long sexual intercourse	Seed, root, and bark	Infusion
Mangifera indica	Anacardiaceae	Malaria, constipation, headache	Bark, stem,	Infusion
Manihot esculenta	Euphorbiaceae	Constipation, body pain, fetish	Leaf	Infusion
Marsdenia latifolia	Asclepiadaceae	help child walk faster, convulsion, purgative	Stem, bark	Decoction, moldy paste
Mimosa pudica	Fabaceae	Pregnancy pain, skins boil,	Leaf	Moldy paste
Moringa oleifera	Rubiaceae	Heart attack, stomach ache, deworming, malaria	Leaf	Decoction,
Musa sapientum	Musaceae	Ulcer, vomiting, diabetes,	Leaves, fruit	Decoction,
Nauclea latifolia	Rubiaceae	Malaria, typhoid, stomachache, headache,	Bark, stem, leaf, root	Infusion
Parkia biglobosa	Leguminosae	malaria, diarrhea, diabetes, hemorrhoid	Leaf, bark	Decoction, Infusion
Spondia mombin	Anacardiaceae	Menstrual problem	Leaf	Decoction
Tecoma stans	Bignoniaceae	Fever, stomachache	Stem, leaf	Infusion
Terminalia ivorensis	Combretaceae	Dysentery, diarrhea	Leaf, bark	Infusion

(continued)

Table 2 (continued)

Scientific name	Family	Disease/sickness cured	Part use	Mode
Terminalia superba	Combretaceae	Heal sore, malaria, diarrhea, skin boil	Leaf, bark	Infusion, squeezed juice
Vernonia amygdalina	Asteraceae	Malaria, elephantiasis, constipation, fetish	Stem, root, bark	Infusion, squeezed juice
Ficus capensis	Moraceae	Stomachache	Bark	Decoction
Ficus laprienrii	Moraceae	External bleeding	Leaf	Decoction
Heinsia pulchella	Rubiaceae	Heat rash	Leaf	Decoction
Hibiscus esculentus	Malvaceae	Diarrhea	Bark	Decoction
Hymenocardia lyrata	Euphorbiaceae	Skin disease	Bark	Decoction
Hyptis suaveolens	Labiatae	Fever	Leaf	Decoction
Ipomoea involucrata	Convolvulaceae	Gonorrhea	Stem	Decoction
Jatropha curcas	Euphorbiaceae	Stomachache	Leaf	Decoction
Mareya micrantha	Euphorbiaceae	Skin disease	Leaf	Decoction
Microglossa afzelii	Compositae	Headache	Leaf	Decoction
Musanga cecropioides	Moraceae	Toothache	Flowers	Decoction
Napoleona vogelli	Lecythidaceae	Cough	Bark	Decoction
Newbouldia laevis	Bignoniaceae	Elephantiasis	Root	Decoction
Ocimum viride	Labiatae	Headache	Leaf	Decoction
Olyra latifolia	Gramineae	Stomach pain	Fruit	Decoction
Parinari excelsa	Rosaceae	Headache	Bark	Decoction
Parinari macrophylla	Rosaceae	Bone fracture	Leaf	Decoction
Phyllanthus discoideus	Euphorbiaceae	Fever	Bark	Decoction
Pterocarpus santalinoides	Papilionaceae	Body pain	Leaf, flower	Decoction

capsule, etc. [72]. However, critiques argue that herbal medicines lack standardization in terms of prescription, consumption, and application. Table (1) presents the common herbal plants around the world and their medical properties, while

Table (2) presents herbal plant used to cure diseases, mode of preparation, and parts of plants used to prepare medication in Sierra Leone.

4 Drivers of Herbal Medicine Use

In both developing and developed countries, the patronage of the populace toward herbal product utilization is on the increase based on details that include but are not limited to the following factors: insufficient knowledge about herb preparation process, complexity of phytochemical properties, dosage misconceptions, and religious and cultural beliefs, among others, which are the influencing factors shaping herbal medicine intake [89]. For some people, herbal medicine is part of their cultural and spiritual belief that can't be easily broken [90]. However, for others herbal medicine consumption and application are associated with witchcraft and evil spirit. Herbal medicine intake and acceptability in developing countries are mainly influenced by trust in plant, tribal belief, as well as the magical power of the practitioners. However, in developed countries, the intake of herbal medicine depends on proven scientific evidence and the accuracy of clinical trial results obtained from series of experiments [91]. Another prominent reason why herbal medicines are gaining popularity is the fact that the drugs are less expensive and easily available as compared to conventional medicines (Table 3). The integration of

Table 3 Factors influencing herbal medicine use and characteristics

Influencing factors	Characteristics	Source
Age and marital status	Elderly people believe more herbal medicine than younger people base on experience	[89]
Accessibility of health service	Long distance to clinics, medical fees	[37]
Accessibility of herbs	Natural herbs are mostly abundant within the patient locality	[92]
Spiritual significance	Supernatural power belief	[89]
Educational level	Less educated people rely on herbs more	[93]
Religious belief	Motivates or discourages herb intake	[94]
Healthcare staff attitude	Most conventional healthcare practitioners embarrass patients	[95]
Cultural beliefs	Influence herbal medicine intake	[96]
Affordability of healthcare services	Some remote places lack healthcare services; hence, herbal medicine is the only option	[97]
Primitive preparation method	The primitive techniques used to process herbal medicines discourage some people	[98]
Cost-effectiveness	Herbal medicines are freely harvested	[99]
Financial income	Does not require huge sum of money	[93]
Lack of awareness	Most people lack awareness about herbal medicine benefits	[93]

clinical trial for herbal drug safety and efficacy assessment of different herbs is critical for the global acceptance of herbal drugs in the near future.

5 Negative Effects of Herbal Medicines and Its Sustainable Development Implication

Although herbal medicines are derived from natural plants, it is worth noting that plant products don't simply mean safe and without side effects [100]. As such, herbal medicine safety has been a major problem in local healthcare system especially in low-income countries and has attracted huge global debate on the standardization of herbal products for people's well-being [101].

Scientific evidence has shown that some herbal medicines have serious side effects such as fatigue, headache, vomiting, and asthma among other negative reactions [100]. Like western or conventional medicines, herbal medicines are not risk-free, neither free from side effects [101]. Some herbs from plants can cause additional sicknesses and stimulate adverse reaction on patient if wrongly prescribed. The perception or idea that herbal medicines are completely safe without any adverse effects is untrue and deceptive [101]. Studies have revealed that a range of herbal medicines have produce undesirable side effects that are life threatening and can lead to early death [102]. Studies conducted by Ernest [103] and Ekor et al. [102] alleged that some herbal products turn into poison leading to the death of most patients. The consequences of wrong herbal medicine prescription and the inadequate knowledge about the potential adverse effects and reactions have sent many patients to their early graves in deprived communities around the world. In spite of the positive contribution of herbal medicines to the sustainable development of societies, herbal therapies remain a threat to the health of many patients due to wrong prescription, little or no clinical testing, or standardization of products [102]. Moreover, the causative factors of herbal medicines' adverse effects are closely associated with mislabeling and misidentification of some herbal products by illiterate or semi-illiterate herbal practitioners [102]. The absence of accurate dosage prescription, proven clinical test, and safety assurance information is complicating the healing potential of herbs related medication around the world.

In such, the negative attributes associated with some herbal medicines properties undermine the sustainable development goal 3 and its related targets. Most herbal products have adverse and irreversible life-threatening side effects that have been killing patients slowly in developing countries, hence impeding the sustainable development drive. The growing report on the adverse side effects of herbal medicines is also impeding the sustainable development of novel drug derived from plants [101]. The root cause of herbal medicines adverse effects is closely aligned with the primitive techniques used in preparing and extracting phytochemical properties and the knowledge level of concern practitioners [101].

6 Challenges Facing Herbal Medicines' Sustainability

Herbal medicine sustainability around the world is facing multiple challenges ranging from deforestation, climate change vulnerabilities, limited research in herbal medicines, conservation and management, among others (Fig. 2). The analysis of these challenges is highlighted below.

6.1 Deforestation

Although herbal therapies have proven to be beneficial to society, however, the therapies' sustainability is face with complex and grave challenges that threatened the continuous availability of herbal drugs. The high rate at which herbal medicine plants are disappearing today is alarming and needs urgent attention to be addressed to avoid extinction. The forest ecosystem is the main reservoir for herbal medicines but is rapidly shrinking despite actions being initiated to halt deforestation and by extension to restore degraded lands globally. The recent Forest Resources Assessment (FRA) estimates show that 420 million of forested areas were deforested between 1990 and 2020 [104]. The high rate of deforestation taking place around the globe presents an uncertain future for medicinal plant existence in few years to come [105]. This situation may then have greater impact on global health system especially for majority of the population in developing countries who find it difficult to access conventional medicines [105, 106]. The high rate of deforestation in most

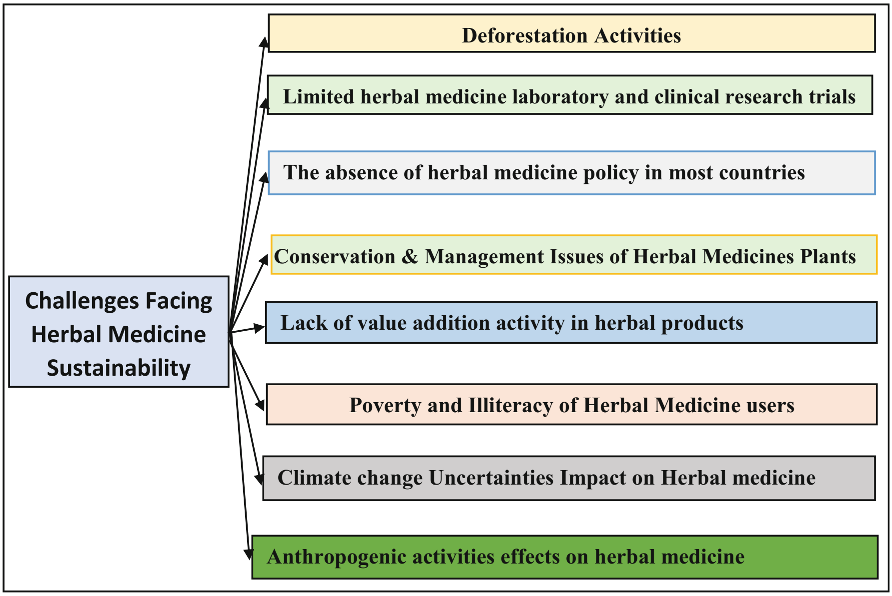

Fig. 2 Challenges facing herbal medicine sustainability

developing countries is connected with biomass energy production [107] and shifting cultivation.

6.2 Limited Herbal Medicine Laboratory and Clinical Research Trials

Herbal medicine has been used to treat various sicknesses and considered the backbone to local healthcare system for decades especially in hard to reach communities. However, only limited clinical or laboratory research work is being conducted globally on a step by step basis to prove the efficacy and safety of herbal medicines as compared to conventional medicine [108]. The absence of adequate clinical experience for herbal medicines affects user confidence and dependability of the product on the international stage. A handful of research conducted over the past years have shown that plant contains antibacterial, antiviral, anticancer, phytochemical, nutraceuticals, and Ayurvedic therapies that can help cure pandemic outbreaks like COVID-19 and Ebola [109]. The absence of adequate number of clinical or laboratory research in herbal medicine therapies has triggered the high rate of mortality resulting from side effects and wrong dosage prescription worldwide [109]. The tropical climate in most developing countries supports herbal plant growth, distribution, and diversity, but the absence of medical research facilities in those countries prevents the actual healing potential of herbal medicine from being realized. According to Alam et al. [109] and Ren et al. [110], some Chinese herbal medicine has been proven to prevent or have the ability to prevent certain critical illnesses from progressing to a deadly and irreversible state. However, the fewer research conducted on herbal medicines hinders the conservation and sustainability of herbal products across Africa and beyond [111, 112].

6.3 The Absence of Herbal Medicine Policy in Most Countries

The safety and efficacy connected with herbal medicines is the growing concern for health authorities and the general public today. The absence of sound and updated policies on herbal medicine development, regulation, monitoring, safety, quality control, processing, and harvesting is limiting the full healing potential of herbal medicines. In addition, the omission of herbal drugs in our healthcare and medical learning system and institutions is jeopardizing the future sustainability of herbal drug acceptability [90, 113]. For instance, the presence of national policy on herbal drugs can help shape and achieve the sustainable conservation and management of herbal plants. Sound policy on herbal medicines can provide the required policy direction and framework needed for sectors to follow for the long- and short-term sustainable utilization of herbal drugs. In some communities of low-income countries, there are by-laws to prevent wildfire outbreak, social unrest, and community forest degradation among others but certainly most don't have by-laws to protect the unsustainable exploitation of herbal plants [90].

6.4 Conservation and Management Issues of Herbal Medicine Plants
